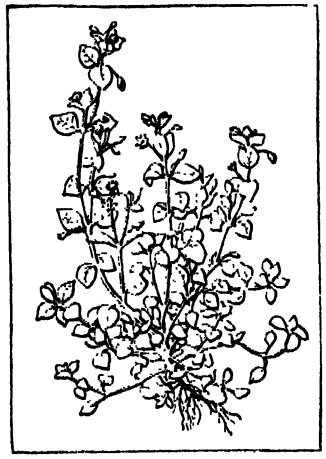
his line during the night with breastworks. *Polk's* right overlapped Thomas's left, and two brigades worked round the breastworks into his rear, but were driven out by his reserves. *Polk's* frontal attacks were repulsed, but Thomas urgently called for reinforcements to secure his left. Rosecrans, believing that *Bragg* was massing all his troops against Thomas, ordered the best part of three divisions to the left. The withdrawal of a fourth (Wood's), due to a misunderstanding, opened a gap in the Federal line, into which *Longstreet* stepped. He had organized a heavy column of attack with eight brigades in three lines and another division forming a flankguard on his left. The Federal right wing, now numbering less than 7,000 men, was swept off the field, but not being pursued, rallied in McFarland's gap. Rosecrans, McCook and Crittenden were all caught in the rout and went to Chattanooga. The break in the Federal line occurred about noon. Thomas was left with five divisions (including one from each of the other two corps) and two or three brigades to withstand *Bragg's* whole army. *Longstreet,* swinging to the right, endeavoured to reach Thomas's rear. Four of Thomas's divisions continued to hold the breastworks in *Polk's* front, but Brannan's division and part of Wood's formed a fresh line nearly at right angles with Thomas's main position along Horseshoe ridge, a spur projecting from Missionary ridge. *Longstreet* had almost enveloped Brannan's right, when two of Granger's brigades under Steedman came to the rescue, and after a desperate struggle dislodged the attacking force, and the Federals held the ridge against renewed assaults, until *Longstreet,* having vainly called for reinforcements from *Polk's* wing, put in his reserve division. The Federals were then driven back from the ridge, with the loss of three regiments captured, to the Snodgrass hill, an elevation 50 ft. lower and over 200 yd. to the rear. Thomas, on receiving an order about 4.30 P.M., had already ordered his left wing to withdraw. *Polk,* who had remained inactive since his repulse in the morning, about 4 P.M. had recommenced his attacks, but the four Federal divisions succeeded in extricating themselves. The right, on Snodgrass hill, was then withdrawn, before *Longstreet* could renew the attack. The Confederate pursuit was halted at 6 P.M., at which hour the whole field was in their possession. Thomas took up a position for the night covering Rossville, and *Bragg's* army being too exhausted to attack next day, after dark (Sept. 21) the Federals withdrew unmolested to Chattanooga. The two armies were probably of about equal strength, from 60,000 to 65,000 each. The percentage of losses was heavier than in any other battle of the Civil War, the casualties on either side exceeding 16,000.

See Gracie, *Truth about Chickamauga* (1911); Geer, *Campaigns of the Civil War* (1926). For a very different version, claiming a Federal victory, *see* Massachusetts Military Historical Society, vol. vii.

(W. B. Wo.)



CHICKASAW, an American Indian people of Muskogi stock for long resident in northern Mississippi, and later forming one of the "five civilized tribes" of Oklahoma. They were foes of the French, friends of the British, and fierce fighters. They never numbered more than about 5,000, which is also their present population, although this comprises many individuals of mixed blood (*See* MUSKOGIAN INDIANS.)

CHICKASHA, a city of Oklahoma, U.S., on the Washita river, 45 mi. S.S.W. of Oklahoma City; the county seat of Grady county. It is on federal highways 81 and 277, and is served by the Rock Island and the Frisco railways. By the federal census of 1950 the population was 15,753, as compared with 14,111 in 1940. Chickasha is the trade centre of a diversified farming, livestock and dairy region. The city has cotton gins, compresses, flour and oil mills. The Chickasha natural gas field is one of the largest in the world. The Oklahoma College for Women, one of the highest ranking colleges of its kind, is located there. Chickasha was founded in 1892. In Indian language Chickasha means rebel.

CHICKEN POX or varicella, a contagious disease characterized by an eruption of vesicles in the skin. The disease usually occurs in epidemics, and the patients are generally between two and six years old. The incubation period is at least two weeks; there are practically no prodromal symptoms, though slight fever for about 24 hr. may precede the eruption. A number of raised red papules appear on the back or chest; in from 12 to 24 hr. these develop into tense vesicles filled with a clear fluid, which in another 36 hr. or so becomes opalescent. During the fourth day these vesicles shrivel up, and the scabs fall off, leaving as a rule no scar. Fresh spots appear during the first three days, so that at the end of that time they can be seen in all stages of growth and decay. The eruption is most marked on areas covered by clothing, but it also occurs on the face and limbs and on the mucous membrane of the mouth and palate. The temperature rarely rises above 102° F. The disease runs a favourable course in most cases, and after-effects are rare. The patient should be isolated. The diet should be light, and the patient should be prevented from scratching the spots, which would lead to ulceration and scarring. After the first few days there is no necessity to confine the patient to bed. In the large majority of cases, it is easy to distinguish the disease from smallpox, but sometimes it is difficult. The chief points in the differential diagnosis are as follows: (1) In chicken pox the rash is chiefly on the trunk, and less on the limbs and face; (2) some of the vesicles are oval, whereas in smallpox they are always hemispherical. They have not at the outset the hard shotty feeling of the more virulent disease; (3) the vesicles attain their full growth within 12 to 24 hr.; (4) the rash appears "in crops"; (5) there is no prodromal period.

The disease is believed to be caused by a filterable virus. A curious and imperfectly understood relationship exists between chicken pox and herpes zoster (shingles). Contact with chicken pox gives rise in some individuals to herpes zoster, while the reverse may also occur though to a lesser extent. There also appears to be a certain degree of cross immunity between the two diseases.

CHICKWEED (*Stellaria media* or *Alsine media*), an annual herb of the pink family (Caryophyllaceae), called also satin-flower, tongue-grass and winter weed. It is native to Europe and Asia and widely naturalized throughout North America and other regions. The plant has weak, reclining, much-branched stems, oval or ovate leaves about 2 in. long and small white flowers. In mild climates it is found blooming throughout the year; in colder regions, as in the north-eastern U.S., it withstands severe frosts and may be discovered blossoming under light snow in midwinter. Various other species of *Stellaria* and also of *Arenaria* are known as chickweeds. Closely allied are the mouse-ear chickweeds (*Cerastium* sp.), various species of which are found in Great Britain, North America and other temperate regions. Most plants called chickweed, though abundant as weeds, are readily eradicated by cultivation. Perennial species are sometimes persistent in lawns.

CHICKWEED, A COMMON GARDEN WEED USED AS FOOD FOR CAGED BIRDS

CHICLANA DE LA FRONTERA, a town of southern Spain, in Cádiz province, 12 mi. S.E. of Cádiz. Pop. (1940) 14,337 (mun., 17,047). Owing to its position in the fertile valley of the Irio, facing the Gulf of Cádiz, 3 mi. W., Chiclana is the centre of a great fruit and vine growing district, and is the favourite summer residence of wealthy Cádiz merchants. Its hot mineral springs also attract many visitors. About 5 mi. S. is Barrosa, where the British under Sir Thomas Graham (Lord Lynedoch) defeated the French under Marshal Victor, March 5, 1811.

CHICLE or **CHICLE-GUM,** the coagulated milky juice (latex) of the sapodilla or naseberry (*Sapota achras*), a tropical American tree of the family Sapotaceae, the fruit of which is widely used in all tropical regions. The latex was first taken to the United States as a substitute for rubber or balata, but be-

ginning about 1890 was imported in increasing quantities, being the basic ingredient of modern commercial chewing gum. The latex is collected by tapping the trunk after the manner followed for gathering balata and gutta percha (*q.v.*); zigzag deep cuts are made to a height of 30 ft. or more up the trunk. The very viscous "milk" oozes out and runs slowly down to a receptacle placed at the base of the tree, the flow lasting for hours and amounting at times to many quarts. The *chicelero* collects the chicle from his "walk" of trees once a day, gathering about a ton per season from 200 to 300 or more trees, which are rested from four to seven years between tappings, about 15% being lost by this treatment.

Practically all the gum comes from Yucatan and adjacent El Petén in Guatemala from wild trees, but attempts to grow it in plantations have been started in British Honduras. The coagulated raw gum is boiled in large kettles until a water content of about 33% is attained; the semisolid mass is then poured into wood forms and moulded into *marquetas* or blocks of about 25 lb. weight, which are packed for transportation in bales of four blocks each.

For manufacture into chewing gum the grayish-brown blocks are remelted, foreign matter is removed, sugar and flavouring substances are added and the finished product moulded and wrapped in packages.

After 1924 the scarcity of chicle resulted in the importation into the U.S. of jelutong from the East Indies, a gum derived from *Dyera costulata* (family Apocynaceae), often called wild rubber. It is mixed with chicle to make chewing gum.

CHICO, a city of Butte county, Calif., U.S., 96 mi. N. of Sacramento on federal highway 99E and the Southern Pacific and Western Pacific railways. The population in 1950 was 12,210; in 1940, 9,287. Almonds, prunes and other fruits, alfalfa, rice and other grains are produced in the region. The city has a match factory, rice mills, fruit-packing houses and creameries, and manufactures steel, aluminum, metal tubes, portable homes, packing cases, millwork, concrete pipe, beet sugar, brooms and sheet metal. Chico State college and a federal plant-introduction station are situated there. In Bidwell park (2,400 ac.) is the Hooker oak which has a diameter of 9 ft. and a spread of 150 ft. Gold and silver are mined in the county, especially around Oroville, the county seat.

CHICOPEE, a city of Hampden county, Mass., U.S., just north of Springfield, on the east bank of the Connecticut river at the mouth of the Chicopee, and served by the Boston and Maine railroad.

It has an area of 22.9 sq.mi., and includes five villages: Chicopee Center, Chicopee Falls, Willimansett, Fairview and Aldenville. The population in 1950 was 48,939; it was 41,664 in 1940 by the federal census.

The Chicopee falls 70 ft. there in less than 3 mi., furnishing power for numerous factories. Among the leading manufactures are radios and electrical appliances, furniture, knit goods, tires and sporting goods.

Chicopee was settled about 1638; was set off from Springfield as an independent town in 1848; and was chartered as a city in 1890. The name is an Indian word meaning "cedar tree." Chicopee Falls was the home of Edward Bellamy.

The bronze-casting industry (later abandoned) was founded there by Nathan Peabody Ames (1803–47), a swordmaker, who in 1836 began the manufacture of cannonballs and church bells. Some of the finest bronze work in the country was done there, including the doors of the national capitol.

CHICORY, *Cichorium intybus* (family Compositae), in its wild state is a native of Great Britain, occurring most frequently in dry chalky soils and by roadsides. It has a long fleshy taproot, a rigid branching hairy stem rising to a height of 3 to 5 ft., the leaves around the base being lobed and toothed, not unlike those of the dandelion. The flower heads are of a bright blue colour, few in number, and measure nearly an inch and a half across. Common chicory is cultivated extensively on the continent of Europe—the Netherlands, Belgium, France, Germany. Its roots roasted and ground are used as a substitute for, adulterant of, or addition to coffee; both roots and leaves are employed as salads; and the plant is grown as a fodder or herbage crop for cattle. In Great Britain it is chiefly in connection with coffee that chicory is employed. A large proportion of the chicory root used for this purpose is obtained from neighbouring continental countries; but a considerable quantity is cultivated in England, chiefly in Yorkshire. It gives the coffee additional colour, bitterness and body.

The blanched leaves are much esteemed by the French as a winter salad, *Barbe de capucin.* In Belgium a variety of chicory called *Witloef* (or witloof) is preferred. There, also, the fresh roots are boiled and eaten with butter, and throughout the continent the roots of witloof are stored for use as salads during winter.

In North America chicory is an introduced weed which has become widely distributed. It is abundant in pastures and along roadsides in the eastern United States and Canada, and is usually considered a pest. As a cultivated crop common chicory is grown to some extent for its root. Witloof chicory (French endive) is grown to some extent as a forcing crop. The roots are grown in the open during the summer and are taken up in the fall to be forced during the winter. If the seed is sown early in the spring in temperate regions having a growing season of five and one-half to six months, the plants may go to seed instead of forming large storage roots suitable for forcing. In such regions seed should be sown in June. The roots may be forced under greenhouse benches, in cellars or out of doors. (*See* also ENDIVE.)

CHICOUTIMI, industrial town and capital of Chicoutimi county, Quebec, on the Saguenay river, 227 mi. N. by E. from Quebec, on the Canadian National railway; it is also connected with Quebec by regular steamship lines. Pop. (1951) 23,216. It is the centre for one of the greatest hydro developments in North America for aluminum production at near-by Arvida. The district has pulp, paper, furniture and textile plants. (C. Cy.)

CHIDAMBARAM, a town of India, in the South Arcot district of Madras, 7 mi. from the coast and 151 mi. S. of Madras by rail. Pop. (1941) 26,212. The fine pagodas at Chidambaram are the oldest in the south of India. The northern frontier of the ancient Chola kingdom is supposed to have been there. The principal temple is sacred to Siva, and is visited by huge numbers of pilgrims.

CHIEF (Fr. *chef,* head; Lat. *caput*), the head or upper part of anything and so, in heraldry, the upper part of the escutcheon, occupying one-third of the whole. The phrase "in chief" (Med. Lat. *in capite*) is used in feudal law of the tenant who holds his fief immediately from the lord paramount (*see* FEUDALISM).

CHIEF JUSTICE. By mid-20th century, every U.S. state constitution with the exception of one carried a section providing for a highest appellate court. Each had a presiding officer—entitled the chief justice in 44 states, the chief judge in Maryland and New York, the president in West Virginia and the presiding judge in South Dakota. Until 1951 the supreme court in Delaware was presided over both by a chancellor and a chief justice, but under a reorganization that year a separate supreme court was created headed by a chief justice.

The manner of selection and terms of office of the chief justices varied widely among the states. The most common single method of selecting the chief justice is appointment by members of the court. This occurred in 28 states under various forms of a rotation system in the 1950s. In 16 of these states rotation took place within a specified period ranging from six months to four years; in 7 the justice with the shortest term left to serve became chief justice for the remainder of his term on the bench; and in 5 the senior justice became chief justice for the remainder of his term.

In the rest of the states the chief justice was specifically designated for his office. Nine states provided for his popular election; eight states for appointment by the governor; and three states for selection by the legislature.

Terms served by the chief justices differed as widely in the states as the methods for their selection. In the 1950s they ranged from six months in Indiana and Iowa to life tenure in Massachusetts and New Hampshire.

In at least 19 states terms of office of chief justices were identi-

cal with those of the associate justices. These states generally included those in which the chief justice is elected to his office or where he is appointed by the governor or legislature. Tenure in this group ranged from 6 to 15 years. Those states selecting their chief justices by rotation, seniority or in accordance with the principle of the shortest term to serve commonly provided for much briefer tenure. In ten such states at mid-century he served two years; in five, one year; and in two, six months.

There were a number of states in which the chief justices had an indeterminate period of office. Thus, in Tennessee the chief justice served at the pleasure of the court; in Maryland it was reported that the term was undefined, although presumably as long as he sat on the court. Besides judicial responsibilities, the chief justice of the court of last resort has innumerable administrative duties. Although most details can be delegated to the clerk's office, many of these functions can be executed by him alone; and his immediate responsibility for administrative matters never can be delegated.

The powers of the chief justices vary sharply among the states. For example, in New Jersey, under the new constitution of 1948, the chief justice was made permanent administrative head of all of the courts in the state with powers of assigning judges to equalize case loads, of requiring judicial statistics on number of cases handled and hours in which the court held session, among others. He was provided with a well-staffed administrative office whose director was appointed by the chief justice. The director was made responsible for all fiscal and business activities of the court. In most states, however, the chief justice does not have supervisory powers over other courts in the state and is not adequately provided either with legal or administrative assistance.

One of the most important developments in judicial administration took place in 1949 when the Conference of Chief Justices was organized. The conference met annually thereafter and provided a forum to discuss improvements in judicial administration by the highest judicial officers in each of the states. The conference requested the Council of State Governments to act as its secretariat, and the council issued a series of reports and memoranda on judicial administration for consideration by the executive and legislative branches in the various states as well as by the judicial departments. (S. Sr.)

CHIEF RENT: *see* QUIT RENT.

CHIEFS. Chieftainship occurs among many but not all primitive peoples at all levels of culture. Its essential feature is the fact that there is always some individual person who is regarded as the official head of the community, and who acts as its leader, ruler and representative. Almost everywhere he bears some distinctive title; and by virtue of his office he frequently enjoys special rights and privileges, and is held in a high degree of honour and appreciation by the other members of the community.

Forms of Chieftainship.—The institution varies according to the size and structure of the community. Among the lower hunting peoples, where the political unit is a small local group, there is generally only a single chief; and this is also the case even among such relatively advanced peoples as the Bantu tribes of South Africa. Elsewhere there may be found a dual chieftainship, as, *e.g.*, under the dual organization (*q.v.*), where each moiety often has a chief of its own. Or, as among many North American and Melanesian tribes, there may be a division of functions resulting in the occurrence of two chiefs, one of whom is generally associated with the economic and religious side of tribal life, while the other is associated with the military and profane aspects. Thus, among the Mekeo peoples of New Guinea, each clan possesses two chiefs, the high chief and the war chief, while among the neighbouring Roro peoples, the high chief is associated with another, whose business it is to see that the orders of the high chief are carried out. In both cases the functions of the high chief are mainly of a sacred kind. Again, as in Polynesia and parts of Africa, where the community is divided into a number of distinct social classes, there may be several chiefs or grades of chiefs. In general, with the advance in political organization, political powers and functions are multiplied and diversified, and this increasing complexity of duties and functions requires the existence of different grades of officers. Thus, the highly organized Iroquois and Creek of North America have civil chiefs and sub-chiefs, chosen for personal merit, and permanent and temporary war chiefs. These several grades of chiefs bear distinctive titles, indicative of their diverse jurisdiction.

In most communities the office of chief is hereditary within a certain family or group of families, so that only members of this family or group of families can become chiefs. Where inheritance is thus recognized it is almost always reckoned in the male line. The chieftainship goes only exceptionally to a woman, and then usually only in default of a suitable male successor. Female chiefs occur sporadically, especially in parts of Africa, but there is hardly a single people among whom the chiefs are regularly women. The rule of descent generally follows that of the community. Where it is patrilineal, the chief is usually succeeded by one of his sons, most frequently the eldest, but primogeniture is by no means universal. In matrilineal societies, the successor is normally a brother of the chief, or one of his sister's sons. Even where the office is thus inherited, however, the succession is often dependent upon the fulfilment of certain conditions. If the rightful heir is regarded as incompetent, or is physically unsound, or suffers from some other disability, he may be passed over. Sometimes he is required to pass through certain tests before he is allowed to take up office.

In other communities the chief is elected. Where this is the case, the choice is often determined by personal qualities or attributes, such as bravery in war, skill in hunting, fishing or some other occupation, ability in council or debate, knowledge of tribal lore and tradition, wealth, generosity, character and so on. Sometimes the chief is elected for a certain period only, as among certain North American tribes, where special war chiefs are chosen to hold office only as long as the war lasts.

Powers and Functions.—These vary considerably; in many parts of the world the office is unaccompanied by the exercise of authority or political functions; at any rate, as far as the administration of justice is concerned. This is the case especially in Oceania and America; in Africa, on the other hand, the chief is often not only the chief judge of his people, but also the law-giver. But his other activities extend over a very wide range. He is often a prominent figure in the economic life of the tribe, and directs hunting, fishing, planting, harvesting, pastoral migrations and trading, according to the mode of life of the people. In many tribes he is regarded as the owner of the tribal land, and regulates its distribution and tenure. He is generally the wealthiest man in the tribe, and often has a very definite function as a sort of tribal banker, providing his people with feasts and, if need be, with the necessities of life, in return for the tribute which they pay him. In war, he is often the actual leader, fighting at the head of the tribe, and where he is too old or too sacred to do that, he plans campaigns and creates *morale* by incantations and medicines. In a number of cases he assigns wives, manages marriages, confirms inheritances, and otherwise makes his influence felt at many junctures of family life.

The chief plays an extremely important part in the religious life of the community. He acts as priest in public rites, prayers and sacrifices; he is frequently the chief magician of his people, and is often held responsible for the weather and the crops, for the health of his subjects and the fertility of their herds. So that, especially among the more highly organized peoples, he is often regarded as sacred or even divine, both during his lifetime and after his death. There are almost always special prohibitions and obligations regulating the relations between him and his subjects, and some form of etiquette and ceremonial to be observed in approaching him. His own health and soundness are in some cases of vital importance to the community. For their sake he must observe many irksome rules of conduct and diet, neglect of which is regarded as harmful not only to himself but also to his people; and bodily weakness may render him liable to deposition and even death.

Origin.—Of the various theories put forward to explain the existence of chiefs, one of the most famous is that in which Sir

James Frazer argues that the chief developed out of the medicine man, and was primarily a magician, his juridical and other functions being a subsequent development. By Davy's theory the chieftainship arose through the concentration of wealth in the hands of one man, whose superior economic position gave him authority over the rest. Rivers, again, stresses the fact that chiefs usually have customs peculiar to themselves, frequently with a similarity between the functions of chiefs in different societies widely separated; and he therefore thinks that the strong basis of "group sentiment" in the government of early societies changes to that of individual authority by the advent of a race of rulers, "enterprising strangers," imposing their ideas upon a community, and becoming chiefs.

There is something to be said for each of these theories, but while each of them lays stress upon a factor of great importance, none of them is exclusive. There is no single factor which can be regarded as having produced chieftainship, which is probably the resultant of a whole series of different factors acting in different combinations in different parts of the world. The essential fact about chieftainship, wherever it occurs, is that it serves as a means of concentrating the activities of the community under the direction of one person. The chief is not merely the representative and leader of the community; he is also frequently the symbol of its corporate unity.

See J. G. Frazer, "The Magic Art and the Evolution of the Kingship" (*The Golden Bough*, vols. i and ii, 1911); R. H. Lowie, *Primitive Society* (1920); G. Davy, *La Foi Jurée* (1922); W. H. R. Rivers, *Social Organisation* (1924). (I. S.)

CHIEMSEE, also called *Bayrisches Meer,* the largest lake in Bavaria, lies 1,600 ft. above the sea, between the rivers Inn (to which it drains through the Alz) and Salzach. With a length of 6 and a breadth of 9 mi., it has an area of about 33 sq.mi., and contains three islands, Herrenwörth, Frauenwörth and Krautinsel. The first is beautifully wooded; it was the seat of a bishop from 1215 to 1805, until 1803 it contained a Benedictine monastery, and today it is remarkable for its castle. The shores of the lake are flat on the north and south sides, but its other banks are flanked by undulating hills. The waters are clear and well stocked with trout and carp; but the fishing is strictly preserved, and steamers ply on the lake.

CHIENGMAI, chief city of northern Thailand (Siam) and terminus of the 467-mi. railway from Bangkok. Pop. (est. 1937) 60,000. The massive but decaying walls of the old city enclose an area of about .4 sq.mi. on the bank of a tributary of the Menam Chao Phya river. The rather fertile valley is 20 mi. wide by 80 mi. long, and is surrounded by high, wooded mountains, inhabited by tribesmen, chiefly Karens. The city has outgrown the walls, and the business district is outside the walled area The last *chao,* or hereditary chief, died in 1939. His son received a pension but did not succeed him. The population consists of Laos (closely related to the Thai), Thai, Chinese and Shans. The American Presbyterian mission commenced work in 1867, its chief local institutions having been Prince Royal college, McCormick hospital, Dara academy and the Chiengmai Leper asylum. Leprosy abounds there, and the asylum had 1,200 outpatients. The Roman Catholic mission had two schools.

From the 13th century until its absorption in the 18th century, the Lao or northern Thai kingdom of Chiengmai fought chronic wars with its ambitious southern Thai neighbour. Twice it was conquered and ruled by Burma, but regained its independence when Burmese rule subsided. The distinction between the Lao of Thailand and the Thai has been almost obliterated. Chiengmai was broken up into a number of tribal states, each with a hereditary chief, co-operating with Thai officials. The small surrounding states of Nan, Prè, Lampun, Lampang and Tern also had hereditary chiefs, but only Lampun has a surviving ruler of the old type. Chiengmai was a provincial or circle headquarters for northwestern Thailand until about 1932, when the circles were abolished.

Roads and trails radiate in several directions and Chiengmai has long been the trading centre of this area—meeting place of Chinese, Burmese, Shan and Thai merchants. The hills are rich in teak, and two large British companies extracted large quantities of this valuable wood. Rice is the chief crop, minor crops being legumes, tobacco and cotton.

CH'IEN LUNG or **K'IEN LUNG** (1711–1799), Chinese emperor, the fourth of the Ch'ing dynasty, was born Sept. 25, 1711. He succeeded his father, Yung Ch'eng, as emperor in 1736. At that time he dropped the name Hung-li, which he had previously borne, and was thereafter known as Ch'ien Lung. When he first came to the throne, Ch'ien Lung was much influenced by his ministers but by 1750 he was in almost complete personal control of the imperial power. About this time he began a succession of wars and campaigns which had substantially increased the territory under Chinese domination by the time of his retirement Rebellions were put down in several parts of the empire during his reign; the territories of Ili, Turkistan, Kuldja and Kashgaria were conquered; and Tibet, Burma, Nepal and Annam were scenes of successful military ventures, some of these territories paying tribute to China for many years afterward. Ch'ien Lung is perhaps best known as a patron of the arts. He himself was a poet, the author of some thousands of verses, but he encouraged not only writers but painters, pottery makers, musicians and scholars. In 1772 he authorized the collection of all important writings extant in the kingdom This collection he ordered housed and catalogued in the Imperial library, together with a history and criticism of each work. During Ch'ien Lung's reign attempts were made by the British to increase trade with China. A mission for this purpose, sent in 1793 under the leadership of Lord George Macartney, came to nought, however, and trade with a number of countries continued, as before, exclusively at the port of Canton. In 1796, having reigned 60 years, Ch'ien Lung voluntarily abdicated, not wishing to rule a greater length of time than his illustrious grandfather, K'ang Hsi. It is probable, however, that he continued to have much influence over his son and successor Chia Ch'ing, until his death on Feb. 7, 1799.

CHIERI, a town and episcopal see of Piedmont, Italy, province of Turin, 13 mi S.E. by rail and 8 mi. by road from the town of Turin. Pop. (1936) 9,601 (town); 13,736 (commune) Its Gothic cathedral (1037, rebuilt 1405), is the largest in Piedmont, and has a 13th-century octagonal baptistery. Subject to the bishop of Turin in the 9th and 10th centuries, it became independent in the 11th century. In 1347 it submitted voluntarily to Count Amedeus VI of Savoy and finally came under Savoy in the 16th century. In 1785 it was made into a principality of the duke of Aosta. It was an early centre of trade and manufacture, and in the middle of the 15th century produced about 100,000 pieces of cotton goods per annum.

CHIETI, a city of the Abruzzi, Italy, the capital of the province of Chieti, and the seat of an archbishop, 140 mi. E.N.E. of Rome by rail, and 9 mi. W. of Castellammare Adriatico. Pop. (1936) 17,575 (town), 30,266 (commune). It is situated at a height of 1,083 ft. above sea level, 3 mi. from the railway station from which it is reached by an electric railway. It commands a splendid view of the Apennines on every side except the east, where the Adriatic is seen. It is an active modern town, upon the site of the ancient Teate Marrucinorum, the chief town of the Marrucini Some scanty remains of the theatre, of a temple (?) and some large reservoirs exist. The Gothic campanile of the cathedral is fine. Close by is the town hall, which contains a small picture gallery. The de Laurentiis family possesses a private collection of some importance. To the north of Chieti is the octagonal church of S. Maria del Tricaglio, erected in 1317. The order of the Theatines, founded in 1524, takes its name from the city. Under the Lombards Chieti formed part of the duchy of Benevento; it was destroyed by Pippin in 801, but was soon rebuilt and became the seat of a count. The Normans made it the capital of the Abruzzi.

CHIFFON. In dress fabrics, one of the most delicate, gauze-like and transparent of all silk tissues. Chiffon consists of a plain woven texture produced from very fine and hard-twisted warp and weft of corresponding denier (counts), with a corresponding number of warp threads and picks per inch, and a soft dull finish. So very delicate and flimsy is the chiffon texture, that

it is easily distorted and pulled out of shape.

The term chiffon has different meanings in different countries. Thus, in France, it signifies a rag; in Rumania, a bleached cotton shirting; in Germany it means a stout, fine, plain woven linen fabric with a smooth finish, and used for shirtings and other garments for underwear; in England, chiffon net (also nun's veiling) signifies a very fine and delicate quality of silk net used as lace and for veils. Chiffon twist signifies a hard-twisted silk thread spun with about 50 or more twists per inch, and used in the production of chiffon tissues.

CHIFFONIER, a piece of furniture differentiated from the sideboard by its smaller size and by the enclosure of the whole of the front by doors. Its name (which comes from the French for a rag-gatherer) suggests that it was originally intended as a receptacle for odds and ends which had no place elsewhere, but it now usually serves the purpose of a sideboard. It is a remote and illegitimate descendant of the cabinet; it has rarely been elegant and never beautiful. It was one of the many curious developments of the mixed taste, at once cumbrous and bizarre, which prevailed in furniture during the Empire period in England. The earliest chiffoniers date from that time; they are usually of rosewood; their "furniture" (the technical name for knobs, handles and escutcheons) was most commonly of brass, and there was very often a raised shelf with a pierced brass gallery at the back. The doors were well panelled and often edged with brass-beading, while the feet were pads or claws, or sphinxes in gilded bronze.

CHIGGER. A name used for a mite (*see* HARVEST-BUG) and for a flea (*see* JIGGER, CHIGGER or CHIGOE).

CHIGI-ALBANI, a Roman princely family of Sienese extraction descended from the counts of Ardenghesca. The earliest authentic mention of them is in the 13th century, and they first became famous in the person of Agostino Chigi (d. 1520), a banker who built the palace and gardens afterwards known as the Farnesina, decorated by Raphael. Pope Julius II made him practically his finance minister. Fabio Chigi, on being made pope (Alexander VII) in 1655, conferred the Roman patriciate on his family, and created his nephew Agostino prince of Farnese and duke of Ariccia, and the emperor Leopold I created the latter *Reichsfürst* (prince of the Holy Roman empire) in 1659. In 1712 the family received the dignity of hereditary marshals of the Church and guardians of the conclaves, which gave them a very great importance on the death of every pope.

See A. von Reumont, *Geschichte der Stadt Rom*, vol. iii. (1868); *Almanach de Gotha;* V. Frittelli, *Albero genealogia della nobile famiglia Chigi* (1922).

CHIGWELL, an urban district of Essex, England, with stations (Chigwell Lane and Chigwell) on the L.N.E.R., 13 mi. N.E. of London. Pop. (1951) 51,775. Area 14 sq.mi. The village, which is mentioned in Domesday, lies in a branch of the Roding valley, fragments of Hainault forest lying to the south and east, bordering the village of Chigwell Row. The scenery of the neighbourhood is described in Dickens's *Barnaby Rudge*, and the King's Head inn, Dickens's "Maypole," still stands. The old grammar school was founded by Samuel Harsnett, archbishop of York (d. 1631), whose fine memorial brass is in St. Mary's church, a Perpendicular structure with a Norman south door.

CHIHLI: *see* HOPEI.

CHIHUAHUA, a northern frontier state of Mexico, bounded N. and N.E. by the United States (New Mexico and Texas), E. by Coahuila, S. by Durango, and W. by Sinaloa and Sonora. The population in 1950 was 841,077, and the area, 94,806 sq.mi. The surface of the state is in great part an elevated plain, sloping gently toward the Rio Grande. The western side, however, is much broken by the Sierra Madre and its spurs, which form elevated valleys of great fertility. An arid sandy plain extending from the Rio Grande inland for 300 to 350 mi. is quite destitute of vegetation where irrigation is not used. The more elevated plateaus and valleys have the heavier rainfall, but over most of the state it is less than 20 in.; an impermeable clay substratum prevents its absorption by the soil, and the bare surface carries it off in torrents. The great Bolsón de Mapimí, an enclosed depression, in the southeastern part of the state, was once considered to be an unreclaimable desert, but experiments with irrigation have shown its soil to be highly fertile. The only river of consequence is the Conchos, which flows north and northeast into the Rio Grande across the whole length of the state. In the north there are several small streams flowing northward into lakes. Agriculture has made little progress in Chihuahua, and the scarcity of water has been a serious obstacle to its development outside the districts where irrigation is practicable. Stock-raising is an important industry in the mountainous districts of the west, where there is excellent pasturage for the greater part of the year. The principal industry of the state, however, is mining—its mineral resources including gold, silver, copper, mercury, lead, zinc and coal.

The silver mines of Chihuahua are among the richest in Mexico and include the famous mining districts of Batopilas, Chihuahuilla, Cosihuiriachic, Jesús María, Parral and Santa Eulalia or Chihuahua el Viejo. There are more than 100 of these mines. The state is well served by trunk-line railways and by several short branches to the mining districts.

Chihuahua originally formed part of the province of Nueva Viscaya, with Durango as the capital. In 1777 the northern provinces, known as the Provincias Internas, were separated from the viceroyalty, and in 1786 the provinces were reorganized as intendencias, but Chihuahua was not separated from Durango until 1823.

An effort was made to overthrow Spanish authority in 1810, but its leader Hidalgo and two of his lieutenants were captured and executed, after which the province remained passive until the end of the struggle.

The people of the state have been active partisans in most of the revolutionary outbreaks in Mexico, and in the war of 1862–66 Chihuahua was loyal to Juárez. The principal towns are the capital Chihuahua, pop. (1950) 110,779; Parral, 120 mi. S.S.E. of the state capital, in a rich mining district, with a population (1940) of 24,231; Ciudad Juárez across the Rio Grande from El Paso, pop. (1950) 128,782; Camargo, pop. (1940) 7,705; Santa Barbara (1940) 13,902; and Jiménez, 120 mi. S.E. of Chihuahua, pop. (1940) 5,175.

CHIHUAHUA, a city of Mexico, capital of Chihuahua state, about 1,000 mi. N.W. of Mexico City and 225 mi. S. by E. of El Paso. Pop. (1940) 56,805; (1950) 110,779. The city stands in a beautiful valley opening northward and hemmed in on all other sides by spurs of the Sierra Madre. It is 4,635 ft. above sea level, and its climate is mild and healthful. The city is laid out regularly, with broad streets, and a handsome plaza with a monument to Hidalgo and his companions of the revolution of 1810, who were executed there. The most noteworthy of its public buildings is the fine old parish church of San Francisco, begun in 1717 and completed in 1789, one of the best specimens of 18th-century architecture in Mexico. It was built, it is said, with the proceeds of a small tax on the output of the Santa Eulalia mine. Other prominent buildings are the Government palace, the Porfirio Díaz hospital, the old Jesuit college (now occupied by a modern institution of the same character), the mint, and an aqueduct built in the 18th century. Chihuahua is served by the Mexican National, the Kansas City, Mexico and Orient (Santa Fe) and the Mexico North-Western railways. Mining is the principal occupation of the surrounding district, the famous Santa Eulalia or Chihuahua el Viejo mines being about 12 mi. from the city. Manufacturing is making good progress, especially the weaving of cotton fabrics by modern methods. The manufacture of gunpowder for mining operations is another old industry.

Chihuahua was founded between 1703 and 1705 as a mining town, and was made a villa in 1715 with the title San Felipe el Real de Chihuahua. Because of the rich mines in its vicinity it soon became one of the most prosperous towns in northern Mexico, although the state was constantly raided by hostile Indians. In 1763 it had a population of nearly 5,000. The war of independence was followed by a period of decline, owing to political disorder and revolution, which lasted until the presidency of Gen. Porfirio Díaz. In the war between Mexico and the United States, Chihuahua was captured on March 1, 1847, by Col. A. W.

Doniphan, and again on March 7, by Gen. S. Price. In 1864 President Juárez made the city his provisional capital for a short time.

CHIKMAGALUR, a town and district of Mysore state, republic of India. The town, about 90 mi. N.W. of Mysore city, had a population of 21,744 in 1951.

CHIKMAGALUR (formerly KADUR) DISTRICT has an area of 2,771 sq.mi. Pop. (1951) 417,538. The larger part consists of the Malnad or hill country, which contains some of the wildest mountain scenery in southern India. The western border is formed by the Ghats, of which the highest peaks are the Kudremukh (6,207 ft.) and the Meruti Gudda (5,444 ft.). The centre is occupied by the horseshoe range of the Baba Budans, containing the highest mountain in Mysore, Mulainagiri (6,310 ft.), and enclosing the Maidan or plain country, a fertile, well-watered region, with the famous "black cotton" soil. The principal rivers are the Tunga and Bhadra, which rise near each other in the Ghats and unite to form the Tungabhadra, a tributary of the Kistna. The eastern region is watered by the Vedavati (Hagari). From all the rivers water is drawn off into irrigation channels by means of anicuts or weirs. The chief natural wealth of Chikmagalur is in its forests, which contain large supplies of the finest timber, especially teak, and provide shelter for the coffee plantations. Iron is found and smelted, and there is corundum in some places. The staple crop is rice, chiefly grown on the hill slopes, where the natural rainfall is sufficient, or in the river valley, where the fields can be irrigated. The district is served by the Southern railway, on which, 23 mi. N.E. of Chikmagalur, is Kadur, from which the district formerly took its name.

CHILACHAP, or TJILATJAP, a port in Java, Indonesia, on the southern coast, in the residency of Banjumas, west of Schildpadden bay. Its harbour, the most favoured by nature in the whole of Java, is formed by the island of Nusa Kambangan, which is long and narrow and lies close to the shore opposite Chilachap, beyond which it projects for a considerable distance and thus protects it from the heavy monsoon seas and swell of the Indian ocean. With the exception of Segoro Wedi bay, Chilachap is the only harbour on the south coast of Java which affords protection during the southeast monsoon, and it is the most important.

The town of Chilachap, which has a population of 28,309, including 670 Europeans and Eurasians, and 1,626 foreign Asiatics, stands on a tongue of land flanked on the east by Schildpadden bay, and on the west by the estuary of the river Donan. The entrance to the harbour is between a projecting headland of Nusa Kambangan and South point, on the tongue of land opposite, and is 1½ mi. wide, but because of a sandbank the navigable channel, which varies in depth from 29 ft. to 48 ft., is narrow. The port has two concrete wharves, 1,350 ft. and 400 ft. in length, respectively, affording mooring places for vessels drawing up to 30 ft. of water at low tide. Chilachap is connected by rail with Batavia, Surabaya, Surakarta and Samarang by a junction with the main Batavia-Surabaya line at Maos. Japanese troops occupied Chilachap shortly after their invasion of Java in World War II.

CHILAS, an important settlement far up the Indus; headquarters of the Chilas subdivision (2,800 sq.mi.) of the Gilgit agency, lying within the Shinaki tribal territory. The settlement is about 100 mi. N.N.E. of Abbottabad, North-West Frontier province, Pakistan. The Chilas settlement, situated 4,010 ft. above sea level, holds an important position with reference to the Kashmir-Gilgit route via Astor. It is connected with Gilgit via Bunji by a metalled road. Chilas also offers a route to Gilgit from the Kaghan valley in Hazara through Babusar pass, shorter than from Kashmir through Burzil pass and gaining importance with the development of the Kaghan valley.

The Chilas valley is rich and green. Although it was included in the British territory in 1893, it kept its autonomy.

CHILBLAIN (*pernio*) is a chronic condition of inflammation and swelling usually of the toes, feet or fingers, accompanied by intense itching. The condition is frequently precipitated by impaired and weak circulation in the extremities and may follow prolonged exposure to cold and dampness or sudden changes in temperature. Ulceration may occur. To minimize the possibilities of chilblain formation, warm loose hose and warm shoes should be worn, and the feet and hands should be dried carefully and rubbed briskly after each washing.

CHILD, SIR FRANCIS (1642–1713), English banker, was a Wiltshire man, who, having apprenticed to a goldsmith, became himself a London goldsmith in 1664. In 1671 he married Elizabeth (d. 1720), daughter of another goldsmith named William Wheeler (d. 1663), and with his wife's stepfather, Robert Blanchard (d. 1681), took over about the same time the business of goldsmiths hitherto carried on by the Wheelers. This was the beginning of Child's bank. Child soon gave up the business of a goldsmith and confined himself to that of a banker. He inherited some wealth and was very successful in business; he was jeweller to the king and lent considerable sums of money to the government. Being a freeman of the City of London, Child was elected a member of the court of common council in 1681; in 1689 he became an alderman, and in the same year a knight. He served as sheriff of London in 1691 and as lord mayor in 1699. His parliamentary career began about this time. In 1698 he was chosen member of parliament for Devizes and in 1702 for the City of London, and was again returned for Devizes in 1705 and 1710. He died on Oct. 4, 1713, and was buried in Fulham churchyard. Sir Francis, who was a benefactor to Christ's hospital, bought Osterley park, near Isleworth, later the residence of his descendant, the earl of Jersey.

Child had 12 sons. One, Sir Robert, an alderman, died in 1721. Another, Sir Francis (*c.* 1684–1740), was lord mayor of London in 1732, and a director of the East India company. He was chosen member of parliament for the City of London in 1722 and was member for Middlesex from 1727 until his death. After the death of the younger Sir Francis at Fulham on April 20, 1740, the banking business passed to his brother Samuel, and the bank passed to his descendants, retaining its identity until May 1924, when it was absorbed by Glyn Mills and Co. Child's bank was at first conducted at the Marygold, next Temple bar in Fleet street, London, and later occupied the site formerly covered by the Marygold and the adjacent Devil tavern.

CHILD, FRANCIS JAMES (1825–1896), U.S. scholar and educator, was born in Boston, Mass., Feb. 1, 1825. He graduated at Harvard in 1846, taking the highest rank in his class; remained as a tutor in various subjects; and after two years of study in Europe succeeded Edward T. Channing in 1851 as Boylston professor of rhetoric, oratory and elocution; and in 1876 became professor of English at the same institution. Child studied the English drama and Germanic philology, the latter at Berlin and Göttingen during a leave of absence, 1849–53; and he took general editorial supervision of a large collection of the British poets. He edited Edmund Spenser (5 vol., 1855), and published an important treatise in the *Memoirs of the American Academy of Arts and Sciences* for 1863, entitled "Observations on the Language of Chaucer." His largest undertaking, however, grew out of an original collection of *English and Scottish Ballads* (8 vol., 1857–58). He accumulated, in the university library, one of the largest folklore collections in existence, studied manuscript rather than printed sources and carried his investigations into the ballads of all other tongues, meanwhile giving a sedulous but conservative hearing to popular versions still surviving. His final collection was published as *The English and Scottish Popular Ballads*, first in ten parts (1882–98) and then in five quarto volumes, which remain the authoritative treasury of their subject. Child worked—and overworked—to the last, dying in Boston Sept. 11, 1896, having completed his task save for a general introduction and bibliography. A sympathetic biographical sketch was prefixed to the work by his pupil and successor George L. Kittredge.

See also Gamaliel Bradford, *As God Made Them* (Boston, 1929).

CHILD, SIR JOHN (d. 1690), English deputy governor of Bombay from 1679 to 1681 and president of Surat from 1682 to 1690, was the first person to be placed in control of all the East India company's factories in India. In 1672 he married Susannah, daughter of Capt. John Shaxton, who commanded the Bombay garrison. He was implicated in the mutiny of Shaxton's troops two years later but was restored to favour through the influence

of his namesake, Sir Josia Child, the powerful governor of the company in London. Like his patron he was utterly unscrupulous and had a passion for intrigue. His tyrannical behaviour as president led to Capt. Richard Keigwin's rebellion at Bombay in 1683. Acting under instructions from London, Child became involved in war with the Mogul emperor Aurangzeb, but the seizure of Surat by Mogul troops forced him to sue for peace. He was not the strong governor that historians had depicted, and his career was a series of ignominious failures.

See R. and O. Strachey, *Keigwin's Rebellion* (Oxford, 1916), which gives evidence that the two Childs were in no way related. (C. C. D.)

CHILD, SIR JOSIA (1630–1699), English merchant, economist and governor of the East India company, was born in London in 1630, the second son of Richard Child, a London merchant of old family. After serving his apprenticeship in the business to which he succeeded, he started on his own account at Portsmouth, as victualler to the navy under the Commonwealth, when about 25. He amassed a comfortable fortune and became a considerable stockholder in the East India company. He was returned to parliament in 1659 for Petersfield; and in later years sat for Dartmouth (1673–78) and for Ludlow (1685–87). He was made a baronet in 1678. His advocacy, both by speech and by pen, under the pseudonym of Philopatris, of the East India company's claims to political power, as well as to the right of restricting competition with its trade, brought him to the notice of the shareholders, and he became a director in 1677, and, subsequently, deputy governor and governor. In order to control the company's affairs in India he got rid of John Pettit, the senior and best-qualified candidate for the presidency of Surat, in favour of a subservient protégé named John Child. He was for a considerable time virtually the sole ruler of the company and directed its policy as if it were his own private business. He has been credited with the change from unarmed to armed traffic; but the actual renunciation of the Roe doctrine of unarmed traffic by the company was resolved upon in Jan. 1686, under Gov. Sir Joseph Ash, when Child was temporarily out of office. He died on June 22, 1699.

Child made some important contributions to the literature of economics; especially *Brief Observations Concerning Trade and the Interest of Money* (1668) and *A New Discourse of Trade* (1668 and 1690). He made various proposals for improving British trade by following Dutch example and advocated a low rate of interest as the "*causa causans* of all the other causes of the riches of the Dutch people." This low rate of interest he thought should be created and maintained by public authority. Child, while adhering to the doctrine of the balance of trade, observed that a people cannot always sell to other countries without ever buying from them and denied that the export of the precious metals was necessarily detrimental. He had the mercantilist partiality for a numerous population and propounded a new scheme for the relief and employment of the poor; he advocated the reservation by the mother country of the sole right of trade with its colonies.

See P. and O. Strachey, *Keigwin's Rebellion* (Oxford, 1916).

CHILD, LYDIA MARIA (1802–1880), U.S. author and reformer, was born at Medford, Mass., Feb. 11, 1802, and died at Wayland, Mass., Oct. 20, 1880. One of the most prominent women of her day, Mrs. Child's present claims to remembrance are the contemporaneous popularity of her stories *Hobomok* (1824), *The Rebels* (1825) and *Philothea* (1836); her editorship of the *Juvenile Miscellany*, the first children's monthly periodical in the United States; and her efforts in behalf of the slaves, freedmen and Indians, including her stirring *Appeal for That Class of Americans Called Africans* (1833) and her editing of the *Anti-Slavery Standard* (1840–44) in association with her husband.

In spite of the 35 editions of her *Frugal Housewife* (1829) and the German, the eight American and the 12 English editions of her *Mother's Book* (1831), these and her many other stories and books on feminism, religion, biography and history have been superseded by later works.

BIBLIOGRAPHY.—*Letters of Lydia Maria Child* (1882), with a biographical introduction by J. G. Whittier, appendix by Wendell Phillips; also, a chapter in T. W. Higginson's *Contemporaries* (1899).

CHILDEBERT, the name of three Frankish kings.

CHILDEBERT I (d. 558) was one of the four sons of Clovis. In the partition of his father's realm in 511 he received as his share the town of Paris, and the country to the north as far as the river Somme, and to the west as far as the English channel, with the Armorican peninsula. In 524, after the murder of Chlodomer's children, Childebert annexed the cities of Chartres and Orleans. He took part in the various expeditions against the kingdom of Burgundy, and in 534 received as his share of the spoils of that kingdom the towns of Mâcon, Geneva and Lyons. When Vitiges, the king of the Ostrogoths, ceded Provence to the Franks in 535, the possession of Arles and Marseilles was guaranteed to Childebert by his brothers. Childebert also made a series of expeditions against the Visigoths of Spain. In 542 he took possession of Pampeluna with the help of his brother Clotaire I, and besieged Saragossa, but was forced to retreat. From this expedition he brought back to Paris a precious relic, the tunic of St. Vincent, in honour of which he built at the gates of Paris the famous monastery of St. Vincent, known later as St. Germain-des-Prés. He died without issue in 558, and was buried in the abbey he had founded, where his tomb has been discovered.

See "Nouveaux documents sur le tombeau de Childebert à Saint-Germain-de-Prés," in the *Bulletin de la Société des Antiquaires* (1887).

CHILDEBERT II (570–595), king of Austrasia, was a son of Sigebert. When his father was assassinated in 575, Childebert was taken from Paris by Gundobald, one of his faithful *leudes*, to Metz, where he was recognized as sovereign. He was then only five years old, and during his long minority the power was disputed between his mother, Brunhilda, and the nobles. Chilperic, king at Paris, and King Gontran of Burgundy, sought alliance with Childebert, who was adopted by both in turn. But after the assassination of Chilperic in 584, and the dangers occasioned to the Frankish monarchy by the expedition of Gundobald in 585, Childebert threw himself unreservedly into the arms of Gontran. By the pact of Andelot in 587 Childebert was recognized as Gontran's heir, and with his uncle's help he quelled the revolts of the nobles and succeeded in seizing the castle of Woëwre. Many attempts were made on his life by Fredegond, who was anxious to secure Gontran's inheritance for her son Clotaire II. On the death of Gontran in 592, Childebert annexed the kingdom of Burgundy, and contemplated becoming sole king of the Franks. He died, however, in 595. Childebert II had had relations with the Byzantine empire, and fought in 585 in the name of the emperor Maurice against the Lombards in Italy.

CHILDEBERT III was one of the last and feeblest of the Merovingians. A son of King Theuderich III, he succeeded his brother Clovis III in 695, and reigned until 711.

See B. Krusch, "Zur Chronologie der merowingischen Könige," in *Forschungen zur deutschen Geschichte*, vol. xxii, pp. 451–490.

(C. PF.)

CHILDERIC, the name of three Frankish kings.

CHILDERIC I (*c.* 437–481), king of the Salian Franks, succeeded his father, Merwich (Merovech), as king about 457. With his tribe he was established around the town of Tournai, on lands which he had received as a *foederatus* of the Romans, and for some time he kept the peace with his allies. About 463, in conjunction with the Roman general Egidius, he fought against the Visigoths, who hoped to extend their dominion to the banks of the Loire; after the death of Egidius he assisted Count Paul in attempting to check an invasion of the Saxons. Paul having perished in the struggle, Childeric defended Angers against the Saxons, recovered from them the islands they had seized at the mouth of the Loire and destroyed their forces. The Saxon chief Odoacer now agreed to serve the Romans and the two chieftains, now reconciled, intercepted a band of the Alamanni. These are all the facts known about him. The stories of his early life by the Franks, of his stay of eight years in Thuringia with King Basin and his wife (or sister) Basine, of his return when a faithful servant advised him that he could safely do so by sending to him half of a piece of gold which he had broken with him and of the arrival at Tournai of Queen Basine, whom he married, are preserved by Gregory of Tours, and have found a place in French epic poetry. After the fall of the western empire in 476 there is no doubt that

Childeric regarded himself as freed from his engagements toward Rome. He died in 481 and was buried at Tournai, leaving a son Clovis (*q.v.*), afterward king of the Franks. His tomb was discovered in 1653, when numerous precious objects, arms, jewels, coins and a ring with his name and the image of a long-haired warrior, were found.

CHILDERIC II (*c.* 653–675), king of Austrasia, was a son of the Frankish king Clovis II, and in 660, although a child, was proclaimed king of Austrasia, while his brother Clotaire III ruled over the rest of the dominions of Clovis. After the death of Clotaire in 670 he became ruler of the three Frankish kingdoms, Austrasia, Neustria and Burgundy. He was murdered in 675 while hunting. He was buried at St. Germain near Paris.

CHILDERIC III (d.*c.* 751), king of the Franks, was the last of the *fainéant* Merovingian kings. The throne had been vacant for seven years when the mayors of the palace, Carloman and Pippin the Short, decided in 743 to recognize Childeric as king. We cannot say whose son he was, or what bonds bound him to the Merovingian family. He took no part in public business, which was directed, as before, by the mayors of the palace. When in 747 Carloman retired into a monastery, Pippin resolved to take the royal crown for himself. Childeric was dethroned in 751 and placed in the monastery of St. Omer. (C. PF.)

CHILDERMAS: *see* INNOCENTS' DAY.

CHILDERS, HUGH CULLING EARDLEY (1827–1896), British statesman, was born on June 25, 1827. On leaving Cambridge he went out to Australia in 1850. In 1852 he was appointed auditor-general in Melbourne, and in 1853 collector of the customs; he carried through a bill for the establishment of the University of Melbourne, and was its first vice-chancellor. In 1856 he represented Portland in the new parliament of Victoria, and was commissioner of trades and customs in its first cabinet. In 1857 Childers returned to England as agent-general of the colony, and in 1860 entered parliament as liberal member for Pontefract. In 1865 he became financial secretary to the treasury. He occupied various posts in the Gladstone ministries. As secretary for war from 1880 to 1882 he was responsible for the administration of the Transvaal War in 1881 and the Egyptian War in 1882. During his term of office the territorial system was introduced, with other administrative reforms of the army. From 1882 to 1885 he was chancellor of the exchequer, and the beer and spirit duty in his budget of 1885 was the occasion of the government's fall. In 1886 he was returned as a Home Ruler (one of the few Liberals who adopted this policy before William Gladstone's conversion) for south Edinburgh, and was home secretary in Gladstone's ministry of 1886. The withdrawal of the financial clauses of the first Home Rule bill was largely the result of his threat of resignation. He retired from parliament in 1892, and died on Jan. 29, 1896.

See the *Life of Childers*, by his son (1901).

CHILDERS, ROBERT CAESAR (1838–1876), English oriental scholar, son of the Rev. Charles Childers, English chaplain at Nice, studied Pāli during his residence (1860–64) as a civil servant in Ceylon. In 1869 he published the first Pāli text ever printed in England, and began to prepare a Pāli dictionary (2 vol., 1872–75), which was awarded the Volney prize by the Institute of France. In the *Journal of the Royal Asiatic Society* he published the *Mahā-parinibbāna Sutta*, the Pāli text giving the account of the last days of Buddha's life. In 1872 he was appointed sublibrarian at the India office, and in 1873 first professor of Pāli and Buddhist literature at University college, London. He died in London on July 25, 1876.

CHILDERS, ROBERT ERSKINE (1870–1922), Irish politician, the son of Robert C. Childers of London, was educated at Haileybury and Trinity college, Cambridge. From 1895 to 1910 he was a clerk in the British house of commons. He served as a trooper in the South African War in 1900 and from 1910 to 1914 was engaged in political work and writing for Irish home rule. During World War I he served in the royal naval air service and in the royal air force, in which he attained the rank of major and won the D.S.C. From 1917 to 1918 he served on the secretariat of the Irish convention. On his demobilization he returned to Ireland and was elected to *dail eireann* as deputy for Wicklow in May 1921. He was principal secretary to the Irish delegation of plenipotentiaries to Westminster, Oct.–Dec. 1921. He afterward opposed the Anglo-Irish treaty of 1922, supported Eamon de Valera in the *dail* and joined the Republicans when they again took up arms. He was captured in Wicklow Nov. 10, 1922, and tried by military court martial on Nov. 17, on the technical charge of having possession of an automatic pistol without proper authority. He was found guilty of treason, and executed on Nov. 24, 1922.

Among his publications are: vol. v of the *Times* history of the South African war, dealing with the guerilla campaigns; a brilliant story, *The Riddle of the Sands* (1903); *The Framework of Home Rule* (1911); *Military Rule in Ireland* (1920).

CHILD PSYCHOLOGY AND DEVELOPMENT. General psychology seeks to give both a description and explanation of the mental processes of adults—processes such as those of learning, perceiving, thinking and motivation. Child psychology is that branch of psychology which devotes itself to the investigation of the processes of psychological growth and adjustment in human beings from conception to adulthood.

Child psychologists strive not only to plot the course of behaviour, ability and attitude change which characterizes the progress of individuals as they mature but also to describe and explain the differences observed between children in the many aspects of their development. With this objective, the discipline, it should be expected, would have nebulous bounds since it is recognized that the individual and his functional environment are interdependent as are also all of the functions of the person to some degree. In order to achieve its purposes, child psychology has cross-fertilized with other sciences such as cultural anthropology, sociology, psychiatry, pediatrics, nutrition and physiology. Vitamin deficiencies and hormone irregularities are not without influence on behaviour and attitude. Comparisons of the behaviour of children in different cultures have thrown into relief the moulding effect of the social milieu.

Child psychology has a rather short history, most of its development as a science having been achieved in the 20th century.

Methods and Techniques of the Science.—The techniques whereby the specific mental functions and behaviour patterns of children are described and analyzed are essentially those used in general psychology since the same processes are studied, though procedural adjustments must often be made to the level of skill and the motivation of young subjects.

The data of child psychology are obtained from a variety of sources. Most frequently children are observed directly either in a casual or in a systematic and controlled way. Casual observation often makes it possible to catch behaviour on the wing; controlled observation is usually necessary to provide detailed descriptions of behaviour and analyses of the influences which alter it. By controlled observation is meant a procedure whereby conditions within and/or about the subjects being studied, as well as the methods of the observer, are regulated or arranged. The controls imposed vary with the purposes of the investigator.

In addition to learning about pre-adult humans through their own direct observations, investigators may gain insights through reports others give of children in questionnaires, interviews or in less formal ways; through records kept by some agency such as a school or clinic, as well as through a study of the things children create; *e.g.*, their drawings and compositions. Introspections by a child himself or by an adult on his own childhood may also shed light on how human beings develop psychologically. That not all evidence of the kinds enumerated can be trusted, however, suggests that the task of data gathering must be surrounded by such safeguards as will ensure accuracy. Since, moreover, much mental behaviour is covert and has to be inferred from behaviour that can be directly observed, the pitfalls which interfere with accurate inference have also to be avoided.

Quantified descriptions of various qualities children have—their abilities, skills, interests, values, social-emotional characteristics

—are achieved usually through tests (objective and projective), ratings and rankings, simple counts and what are known as time-sampling methods.

Since the investigator as he observes children directly in their activities may not be able to see and hear quickly enough to give an accurate report of what happens, he may find it profitable to obtain a permanent record which can then be analyzed at leisure. Hence, cinematic and sound recording are among the routine techniques of the child psychologist. The movie and the wire or plastic sound records obtained can be presented at any desired tempo and can be reviewed an indefinite number of times.

To discover the usual course of developmental change in children, two chief methods have been employed. The same group of subjects is followed through a period of years, or different groups of children at successive ages are studied. The latter cross-sectional method is less time-consuming since the investigator is not obliged to wait for his subjects to grow up; but the resulting composite image is likely to give us the impression that development in the case of the individual is smoother and more regular than it actually is. In fact, no child, as he matures, may follow exactly the pattern of the mean.

Whereas from some points of view the first method, the longitudinal, is preferable—since it yields a picture of the development of each individual as well as of the trend in the total group—it is not often used, not only because of the slow rate at which data can be accumulated but also because subjects are lost with great rapidity because of the difficulty of sustaining co-operation and of population mobility. An investigator might well lose two-thirds of his subjects over a period of 18 years. Those subjects who were still available at the termination of such a long study would, doubtless, be a highly selected group and hence would not depict well what is typical.

MENTAL DEVELOPMENT

Both the fact that people differ and the fact that they are alike in many of the aspects of their development need consideration. This first section will sketch roughly what tends to be the rather usual pattern of unfolding in children in a culture such as that of the United States; *i.e.*, give a sort of developmental time schedule for the average child. A brief discussion of the problem of individual differences is reserved for a later section.

Although the most striking characteristics of development are that it is continuous, irreversible and its parts all interrelated, any description of its course must be cross-sectional and selective—deal with discrete bits of behaviour at arbitrarily chosen landmarks. The reader must fill in with his imagination the gaps between the segments selected for mention.

Prenatal Development.—If the beginning of psychological life is to be understood, the child must be studied before birth. Because of the fact that the prematurely delivered foetus which is more than six months of age can live, if given proper care, and hence can be available for visual inspection, the behaviour and ability of the foetal infant during the last three months of the prenatal period are better understood than are those of younger foetuses. Direct observation of aborted foetuses who are younger than six months must be distorted by the fact the infant is dying when under visual scrutiny. Some of the indirect means devised to throw light on the activities of young foetuses involve the use of palpation, X-rays, the stethescope, the electrocardiograph and introspections by the pregnant mother on the felt movements of the child she is carrying.

Many behaviour patterns once thought to appear only after birth we now know can be elicited much earlier. By the 2nd month after conception, for example, a primitive sort of sucking response can be aroused; by the 11th week, grasping; by the 4th month, rudimentary respiratory movements; and by the 7th month, the corneal reflex. Quickening may be felt by the mother as early as the 16th week. The foetus' heart begins to beat at about the 3rd week.

There is evidence that learning can occur before birth, but how much and what is usually learned is not clear. While the one-time belief that a mother could "mark" her child physically by the specific thoughts and feelings she experienced while pregnant has long been exploded, it is not out of the realm of the possible that her mental state, since it affects her physiological condition, may have some influence on the foetus' psychological life. We know it can influence the foetus physically.

The Newborn.—The neonate is no automaton, no mere bundle of reflexes, but rather an organism with an extensive repertoire of responses so co-ordinated as to make possible, if it is given some protection, its survival in this everchanging and infinitely complex world. Its responses are, to be sure, largely vegetative, but the psychological registration of these in feeling should not be overlooked. A few hours after birth, for example, crying on the part of the infant will accompany the "hunger" contractions of its stomach. The newborn can be roused via all sense modes if the stimuli are such as to have organic significance. Sometimes the infant's response is seen chiefly in increased or decreased movement of a massive sort or in changes in circulation or breathing. Often, however, the response appears more specific and localized—such as fixating, converging on or following a light or closing the hand when the palm is stimulated. The neonate reacts less vigorously to pain than do older children and, strangely enough, it does not shed tears when it cries. Whether its discriminations embrace those between the various colours or beween different odours is still something of a moot question, but it seems not unlikely that it can sense certain gross differences within these modalities.

The baby who has just arrived seems capable of being upset not only by interference with its biological needs (*e.g.*, by food, water and air lacks, too great heat or cold and by pain) but also by sudden intense light, sound or equilibratory stimuli. There is disagreement, however, as to whether it can be said that the new infant shows differentiated emotions. It seems clear enough, even though an occasional faint smile may be seen flickering across the newborn's face, that pleasant excitement is generally lacking. How safe it is to assume that differentiation has occurred in the area of unpleasant emotion (*e.g.*, that anger and fear have emerged) is a point that is debatable.

Even though the newborn sleeps about 20 hrs. a day and spends much of his waking time in nursing, he is still a learner. Conditioning with respect to certain details of the feeding routine are some of the learnings that have been reported to have occurred within four to five days of birth.

The Yearling.—By one year the infant has made great strides and has quite a distinct personality. The yearling seems to be making his most dramatic advances in locomotion. Not only has he greatly expanded his horizon by learning to sit alone, but he can voluntarily change the horizons upon which he looks; for he can creep, pull himself to standing and walk, if led by the hand. The experience of stepping out on his own usually comes a couple of months later.

Manual explorations, too, are among his enthusiasms. He seems to have a compulsion to touch and finger articles and grabs avidly for most everything in sight. Even so tiny an object as a crumb may attract his attention and, when it does, he can appropriate it with a neat pincer grasp. But his manipulation does not stop with mere grasping and holding, as it did earlier. The objects he picks up are likely to be combined in some activity. The yearling enjoys putting objects into containers, such as a ball into a box. The object, to be sure, does not stay put long, for he retrieves it promptly with the same flourish displayed in depositing his cache. If we would point to his lacks rather than achievements in the case of manual skills, we might mention his awkward voluntary release of objects whose position he is trying to control. He tends to have difficulty, for instance, according to Arnold Gesell, in dropping a pellet into the mouth of a small bottle, and he does well if he can build a block tower of even two blocks.

In self-help he is beginning to make progress. He drinks from a cup easily and can hold it alone, although, of course, he needs both hands to steady it. Bits of solid food such as meats he finger-feeds himself. If he uses a spoon, he tends to turn it over as he lifts it to his mouth, rather than to keep it upright, with the result that any self-feeding he does with a spoon may consign more food to his chin and bib than mouth.

That his infancy is about behind him is attested by the fact that he is now on a three-meal-a-day schedule. If he has a bottle, it usually is just one a day. His social advance is revealed also by his sensitivity to approval and disapproval. He can even inhibit his impulses a bit if the person who is requesting him to refrain from some act remains close at hand and frowns or displays some other sign of disapproval. The baby of a year is likely to shy away from strangers, an attitude which, while it does not seem like a social advance, does reflect his budding understanding of human groups and alliances.

In the matter of verbal communication the year-old infant has not made much progress. He has spoken his first word but at best this is little more than a vocal stunt which he performs on request. In spite of his lack of verbal skill, it must not be overlooked that he is making progress in important aspects of language. His eager interest in the world about him and the resulting perceptual differentiations he makes as well as the understandings he gains will provide him with meanings without which the words he is soon to acquire would be hollow shells.

The Toddler.—By two years the child is a toddler and explorer. He can even run. He is likely to fall frequently not only because of his light mass, small base and relatively high centre of gravity but also because of his lacks in foresight and learned motor skills. The climbing of stairs and the walking of simple inclines fascinate him. When he climbs stairs, he marks time (*i.e.*, brings one foot up to the level of the other before advancing) and holds on to the balustrade. He thinks it a feat to jump down one step without falling. Not only can he carry himself almost anywhere he wants to by walking and running, but before he is three he is frequently a master of one form of vehicular locomotion; *i.e.*, he can ride a tricycle, if given opportunity to learn.

In manual skills, as in locomotor, he has made progress. His hand preference is fairly well established. He helps, when being dressed, chiefly by holding his various members in readiness; but pulling off his cap, shoes, stockings and mittens are not beyond him. If his food is soft or finely cut, he can feed himself with a spoon, though the activity takes considerable concentration. The spoon he holds fist-fashion. He can drink from a cup and not infrequently holds it with one hand. His improvement in co-ordination is revealed by the fact that he is seen frequently pushing a baby carriage, covering a doll, putting pegs into a simple peg board. Opening and closing containers and screwing and unscrewing are sources of great delight. Although he is usually unable to make a representative drawing (his are scribbles), the two-year-old likes pictures and tends to puff with pride as he names the common objects and animals portrayed in his picture book. He can often recite a short nursery rhyme or supply the final words to the lines of the rhyme as the adult reads a familiar jingle. In fact, his verbal skill is considerable; a vocabulary in use of approximately 300 words has been estimated as about average. One-word sentences, however, predominate in his speech, though he is beginning to put words together. When the two-year-old refers to himself, he usually does so by name. Pronouns are rather conspicuously absent from his speech, but before he is three the first person singular and the pronominal adjective, "mine," may be overworked, especially when he is playing with his peers. The two-year-old, in addition to knowing his name, knows his sex and that he is a little person; i.e., he has begun that classification and diagnosis of himself which will occupy him endlessly in his life.

As might be expected, since correct pronunciation involves fine auditory perception and delicate motor control, the toddler's pronunciation is far from perfect, letters in his words being frequently omitted and misplaced or wrong ones substituted.

It is possible to guide the behaviour of the two-year-old somewhat by simple directions; for instance, he can hold a limited task in mind, such as returning with the toy he has been sent into the next room to fetch. Control of him, however, has still to be chiefly nonverbal. Nor has he internalized to any extent the mechanisms which would help him inhibit his impulses. If told not to do something, he cannot yet be trusted to desist when the adult's back is turned. This is not necessarily because he is perverse but merely that he has not yet formed the mental cues which will help him to remember and control. His conscience, like his good intentions, is short-lived and poorly formed.

That he has come a great way in his socialization is indicated by the fact that he has fairly dependable bowel control. In the matter of bladder control his success is not so great. While daytime accidents are not usually frequent, he is likely to wet himself at night. He is down to one nap a day and this usually in the afternoon. Awake now about ten hours a day, he has much time for getting acquainted with his universe. No wonder he learns rapidly.

In his social relations the young two-year-old is more adult-centred than peer-centred. At nursery school, for instance, he is more inclined to ignore or play alongside other children than to play co-operatively with them. Objects and materials seem to interest him more than do children, though he may spend considerable time watching the latter and may snatch things from them if they have something that appeals to him. In the main, he has few techniques of defense.

If the adults caring for the toddler are and have been relatively fearless and have dealt with him wisely, he is likely to have few fears. Among the fears common at this age, says Arthur T. Jersild, are those of animals, falling, sudden loud noises, strangers and strange settings. When distressed, the two-year-old cries readily and, when thwarted, often merely explodes—lies down on the floor and kicks or bangs his head but fails to direct his attack toward those who have interfered with his desires. He is easily made cranky by hunger, fatigue and colds and has little self-control. In general, he lacks sympathy with and insight into the sufferings of others. If another child cries he may, however, watch in a rather troubled way.

The School Entrant.—The fact that formal education usually begins around six years indicates the belief of society that the child by this age can take reasonably good care of himself and can work with a group. The six-year-old's control of his body is shown by his ability to climb almost anything in sight, skip, hop and gallop, as well as run fleetly.

He grasps a knife, fork, spoon and pencil with a fingerhold—a form which makes for much finer control than the fisthold which characterized him at two years. In the matter of dressing and undressing, he is quite independent, only an occasional snugly fitting rubber or awkwardly placed button producing calls for help. With assistance on ears and back, he may give himself an acceptable bath. He can tie a bow knot, use a pair of scissors with fair control, paste and hammer, as well as saw in a fashion. His wood products, such as boats and wagons, begin to resemble what he is trying to represent. His drawings, too—people, houses, trains, autos, planes and flowers are among his favorite themes—are now recognizable. For the spatial relationships of the major parts of the objects he tries to represent he has some feeling, but his sense of proportion is none too good; those parts in which he has a special interest or for which he has enthusiasm are usually portrayed disproportionately large. The doors and windows in the houses he draws provide more than adequately for exit and light.

That in representing he pays attention to more than the spatial relationships of the parts is apparent in that, when painting or colouring, he tends to portray objects in realistic colours. When he strings beads he often follows a pattern instead of merely interesting himself in getting the beads on the string, as he did earlier. This following of a bead pattern may involve other discriminations such as those of simple number. In fact, the school entrant has made significant progress in the development of a conception of number. According to Lewis M. Terman, he can count 13 pennies and can select out of a pile, on request, groups of objects numbering as many as 10.

The most significant achievement of the sixth year, in the case of the schoolchild in the U.S., is that of learning to read. Reading, however, might better be designated word-calling at first, for only gradually does the child learn to read along continuously and get ideas from his reading.

With baby talk largely a thing of the past, and in spite of the fact that he is beginning to shed his milk teeth, the school entrant's enunciation is not unlike an adult's. In his six years he has

acquired an active vocabulary of about 2,500 words. Compound and complex sentences are common among his verbal products, his sentences averaging around five words. This fact indicates his thinking has reached a respectable degree of abstractness since qualifiers are not unusual. The six-year-old's use of the present, past and future tenses reflects some understanding of time, though he does show his youth by the extent to which he lives in the present—by his relatively infrequent references to the past and future and also by his inability to work toward a remote goal.

Important in revealing his social progress is the fact that the six-year-old cries relatively infrequently, in contrast with the two-year-old, expressing his displeasure and wants more often in words. If he is angry he tends to work his way through the difficulty by the use of language rather than as he did earlier by loud lament or physical force. Emotional explosions as undirected as tantrums occur rather seldom. Instead, his attacks, when he is annoyed, tend to be well directed, whether they are verbal or physical.

Having to defend himself and his status in a society which is highly competitive, a child of six in the U.S., for instance, is already rivalrous and status-conscious. Despite rivalrous attitudes, however, it is not beyond him to share spontaneously some of his possessions, to take turns and to listen quietly when another person has the floor. It is sometimes, of course, difficult to persuade him that these procedures are in his interest. With guidance in a project, he may be able to take a role which complements the roles of others and to sustain this role for a number of days. Among his play activities are likely to be such co-operative enterprises as playing school, house, store and war. In such techniques for manipulating others as flattery, bribery, bargaining, threats and forming counteralliances he tends to be fairly well practised.

The child of six can enter into the more intimate types of social relationships, too. He usually has a special friend or two whom he seeks out and, if need be, defends, albeit his alliances are not distinguished for their permanence. Among racially mixed groups he is likely to prefer those of his own race. Association with those of other races tends, notwithstanding, to be free and easy. Also he associates with the members of both sexes rather willingly, though he is seen more with the members of his own sex.

A further sign of his increasing socialization is the fact that when not too sorely tempted, the six-year-old can control himself, even in the absence of the enforcing authority. He does have a conscience and finds it difficult to bear or conceal guilt. Since the school entrant is governed little by broad principles, his morals tend to be specific to the situation; he may be honest or generous in one situation and dishonest or selfish in another.

Among the fears common in children of this age, according to A. T. Jersild, are likely to be those of the dark, robbers, animals, being alone, dangers associated with imaginary creatures, and bodily injury through drowning, fire or traffic accidents. Those fears of sudden loud noises and high places so characteristic of young children have in most cases disappeared. It is conspicuous that the fears of the child of six are roused less than they were at a younger age by present events and more by symbols of objects, persons or situations which he believes threaten his welfare. These threats may, of course, be more imaginary than real. Indeed the boundary between the real and imaginary is still somewhat blurred at times for the six-year-old. When he listens to the radio, which he likes to do, he often believes the action and characters are real.

Because he has just entered school and is having to work out adjustments to a new and usually taxing social environment, he may be more emotional, explosive and less well-adjusted than he was somewhat earlier. Insecure in the school environment and in his relations with his new companions, he may take out his irritations on the members of his family. It is well to realize also that his parents may have been dwarfed some in significance by the emergence of the teacher as a new authority.

The Preadolescent.—Since girls are more accelerated in their development, the picture given in this section is chiefly of girls of about 10 years and boys of about 11. The picture, it should be added, blurs sex differences even more than has been the case thus far.

The preadolescent period is often called the gang age, since children of this age seem to go in packs. Informal clubs, pass words and code language are their special joy and are signs of the increasing dependence of preadolescents on their peers and their decreasing dependence on adults. In their social interplay children just entering the second decade tend to be somewhat rough. The flaunting of untidiness is not unusual among them, and the lack of social amenities in her preadolescent son has been many a mother's despair. Practical jokes, such as poking and tripping, and slapstick comedy are forms humour takes. The comic strips (usually not comics but pictorial detective and adventure stories) are read avidly and programs of similar type on the radio are listened to. Favourite play activities for boys of this age in the United States, for instance, are roller skating, bicycling, romping, carpentering, chasing, swimming, coasting, skating, marbles, baseball and football. The girls tend to favour more quiet play, although rope jumping, jacks and hopscotch are at the peak of their popularity. Popular among girls, too, are sewing clothes for dolls, playing the piano for fun and listening to the radio.

A deep gulf separates the boys and girls, partly because the members of each sex are not equally vigorous and hence have developed dissimilar play interests, and partly because they are so anxious to conform to the pattern society holds for their sex that they feel they cannot run the risk even of association with the opposite sex.

The interracial distance, like the intersex distance, tends to be great in the preadolescent period.

At 10 to 11 years, then, it is clear the child tends to be leaguing himself strongly with his peers and those of his own social group. It should be no surprise to find that he is less respectful of adult authority than he was earlier. A number of these young children even engage in some of the minor forms of delinquency such as petty larceny. These delinquencies are usually committed in gangs.

If we look back and consider from where these preadolescent children have come, their school accomplishments seem considerable. Reading for them is usually no longer a difficult task. Although the comics rank high in the materials read by boys and girls of preadolescent years in the United States these children tend to enjoy books also. The boys are inclined to like particularly books of adventure, mystery and magic, tales of children of other lands and realistic accounts of animals. Girls tend to like stories of home and school life.

There is some evidence that the average preadolescent's comprehension vocabulary may be as extensive as 12,500 words. The 10-to-11-year-olds express themselves easily in speaking, the average length of their sentences being between six and seven words, and among their verbal products will be found virtually all important language forms.

In contrast with their verbal skill, children of this age still do not have much fluency in communication through writing. Their themes and letters lack flexibility as well as variety of expression. They have the motor ability to write easily, their expression being blocked among other things by their preoccupation with the details of spelling and of written forms. They typically have only a limited command of the intricacies of capitalization, punctuation and paragraphing but do apply the simpler rules successfully.

Their progress in mathematics has usually carried them to a level at which they can deal with the elements of addition, subtraction, multiplication, division and with simple decimals.

The Adolescent.—Adolescence is the period, usually from 11 or 12 to 22 or 23 years (boys later than girls), when the individual is completing his growth and the development of the structures and functions which make procreation possible. The onset of menstruation is generally taken as the beginning of adolescence in girls, a custom which should not blind us to the fact that significant hormonal and growth changes precede this event. In the male no such convenient landmark is available. The menarche occurs most frequently in girls between 12 and 14 years, although the range of ages at which it appears is great, while puberty in boys is delayed on the average from a year and a half to three years longer.

When the individual begins to take on the physique of the adult

and experiences the effects of his altered physiology, life tends to change rapidly for him. While societies differ greatly in the clarity with which they define the adolescent's role for him, in U.S. society the route from childhood to adulthood is not well outlined. The young adolescent finds the people about him treating him in varying degrees as an adult. Since children in the United States are usually not active participators in the work of adults, an adolescent may find that his mother, who still thinks of him as a child, gives him little responsibility and humours him, whereas the proprietor of the drug store where he serves as errand boy expects of him mature judgment and dependability. Forced into the role of an adult one minute and that of a child the next, the youth tends to be confused.

As he comes to think of himself as grown, we find the adolescent asserting his independence and wanting to be responsible for his own destiny. With respect to peer dictates, however, he is inclined to be a severe conformist. Whether or not he is to wear a certain type of clothing when his friends do is a momentous matter. When the code of his peers conflicts with that of his home, the latter sometimes is sacrificed, though as a rule not without struggle. Delinquency and radicalism approach their maximum at this period.

The young adolescent tends to spend much time with his peers; this is the age of the drugstore and pool-hall gangs. Clubs and teams are matters of much importance. The adolescent is increasingly able, as he matures, to submerge his interests as he elevates those of his group. His friendships tend to be intense, both with older persons and with his peers, keeping his life from assuming too pale a cast. He loves idealistically, even though rather egotistically, and is anxious to be approved. Members of the opposite sex who were heartily scorned a few years earlier are now often worshipped. Strong heterosexual interests, along with physical maturation, tend to appear earlier in girls than in boys. With these interests comes concern over grooming. The adolescent's looks are likely to be the source of much anguish to him—a few unwanted pounds or inches may make life miserable, and sad is the youth if acne mars his skin. Much conflict stems from the fact that adolescents differ greatly in the time at which they experience their growth spurt and sexual ripening. A youngster who is still in his prepubertal period at 15 when all his friends have taken on adult appearance is likely to doubt his normality. He may even find himself rejected by his peers.

Since the role of the male in the United States is that of wage earner and provider, boys in that land approaching adulthood become increasingly concerned with the problem of selecting an occupation and earning money. Girls, too, give some heed to the problem of their future work, for no longer is it lacking in respectability for women to engage in gainful occupation, even after marriage.

Though young in experience, adolescents tend to be strong in physical capacity. Girls, it has been reported, reach the peak of such motor abilities as running and throwing at about 14 years—while boys approach their peak in these skills about 3 years later. The sexes become sharply differentiated in strength and endurance, on the average, after 13 years.

It is difficult to say when the peak in intellectual capacity is reached. In simple functions like memory span the maximum occurs earlier than is true in the case of the more complex cognitive activities. The adolescent who remains in such stimulating environments as a university seems to increase his score in tasks of the type included in the so-called intelligence up to at least 20 years. The adolescent's command of language improves steadily with the years, and the average high-school senior has a comprehension vocabulary, according to one estimate, of 15,000–18,000 words. Whether or not a youth's vocabulary increases after he leaves high school will depend largely on the demands of his social and occupational environments.

INDIVIDUAL DIFFERENCES

As was stated earlier, the developmental picture just sketched is that of the average child and in one culture. But each child is unique, and few are average in even most respects. Among children are the feeble-minded and the geniuses, the right-handed and left-handed, the stutterers and those with fluent speech, the delinquent and the moral conformist, those who attack every one who crosses their path and those who seldom think a hostile thought. Suffice it to say that the genes inherited and the environments, intra-uterine and postnatal, which have surrounded the children cause the heterogeneity we find in the child population. Both nature and nurture influence every trait and behaviour a child displays, but in the case of some qualities the dissimilarities children exhibit are more frequently reflections of the varied environmental pressures to which the children have been subjected, whereas in the case of other qualities the population variance seems to derive more from genetic influences.

Not a great deal is known of the role heredity plays in producing psychological variance, though such evidence as is available suggests that in some areas the weight of heredity is great. More is known about the likely effects of at least some environmental forces. Environmental effects can best be gauged either by studying the same individuals under different circumstances, for then surely heredity is held constant, or by comparing individuals such as identical twins, who have developed from the same fertilized egg and, hence, have the same genes. It is impossible, on the other hand, to hold environmental forces completely constant, while heredity is varied. Even children growing up in the same household may have different nurturing. The fact of family resemblance alone proves nothing conclusive about the effects of either nature or nurture.

Environmental Influences.—The forces in the environment which cause people to differ are, of course, almost infinite in number. Among important classes or complexes of these influences are those of race, nation, social and income class, individual family attitudes and practices, schooling, disease and nutrition. That code of behaviour, values and practices to which groups such as a race, nation or social class hold their members we customarily call culture. The details of such a code, for conformity with which the child is rewarded and for deviation from which he is punished, are astoundingly numerous. Children are made to follow the endless minutiae of the group's feeding rituals, to learn the group's language with all that implies in the way of the determination of thought, to respond in certain ways to each class of person (*e.g.*, their elders, their peers, the younger, the sick or those in various social and occupational positions) and to conduct themselves in accordance with the behaviour forms considered appropriate for each type of situation and setting. Most of what is to be valued and what is to be abhorred is dictated.

Within each such group as a race or nation there are subgroups, each with its code. The family is an important subgroup since it is the chief conveyor to the child of the social traditions of the race, nation and social class to which it belongs as well as of its own unique traditions. It is an agency which tends to make its influence felt during most of the individual's life and is especially strategic because of its functions of ministration and protection. If a child's parents are cautious, they will warn him innumerable times of dangers and hazards; if they are hostile, he will have felt the chill of their irritation, hate and resentment with untold frequency. It is no wonder, then, we find that children whose parents are rejecting tend to be hostile, tense, distractible and avid for attention; or that children who are overprotected tend to be tender, adult-centred and conforming. A child from an upperclass family lives by a code of manners and morals so different from that of a lowerclass child that the two may find it difficult to converse. One class may value formal education and the fruits thereof, disapprove physical attack as a means of settling difficulties and put rigid taboos on certain sex practices such as masturbation, while another class sanctions the exact opposite of these values and behaviour patterns.

Disease and malnutrition also contribute to individual differences among children. An infection resulting in encephalitis has the power to change the whole course of the individual's life—make a dissenter out of a docile soul, a mental defective out of a genius or a cripple out of an athlete. Malnutrition, like disease, may warp the body, ready it for invasion by bacteria and viruses and colour the individual's whole outlook by limiting his energy

BY COURTESY OF YALE PSYCHO-CLINIC, YALE UNIVERSITY

GROWTH OF CHILD BEHAVIOUR FROM BIRTH TO FIRST BIRTHDAY

These pictures of a normal infant under systematic observation, were made in the photographic laboratory of The Yale Psycho-Clinic. They show characteristic behaviour patterns at advancing age levels as follows:

1. At *one week* of age the infant stares at large objects. Lies with head on side, extending arm on same side (tonic neck reflex; cf. 3 and 4)
2. At *6 weeks* of age, lifts head when held in ventral suspension
3. At *8 weeks* clasps a ring, without visual regard
4. At *12 weeks* follows with eyes a small moving ball
5. At *16 weeks* intently regards cube on table
6. At *20 weeks* makes crude approach on spoon
7. At *24 weeks* picks up cube on the table
8. At *28 weeks* bangs a cube on the table
9. At *32 weeks* plucks a tiny pellet
10. At *36 weeks* holds two cubes and attends to a third
11. At *40 weeks* explores the clapper of a bell
12. At *44 weeks* secures a ring by pulling a string
13. At *48 weeks* lifts a cup to secure a cube
14. At *52 weeks* makes a crude imitative scribble with crayon

or disturbing his body's functioning. Rickets, pellagra and beriberi are forms of malnutrition with massive cumulative psychological effects.

CHILDREN, CARE OF: *see* INFANCY.

CHILDREN, DISEASES OF. The major developments in this special branch of medical science, known also as pediatrics, took place after the turn of the 20th century. Prior to that time there existed but little knowledge of, or interest in, the special problems of child health. Infants and young children were regarded merely as "miniature adults," whose physical, mental and emotional disorders required no special consideration beyond that afforded mature persons. As a result of this attitude and the undeveloped state of medical science and practice, the incidence of disease and the mortality rates among children were appalling; 20% to 40% of all infants born alive died during the first year of life. Of the total deaths in the population, three out of four occurred in children under 12 years of age. However, as a result of revolutionary advances in the field of pediatrics and intensive application of sound public health principles, death rates among children at mid-20th century were reduced to one-tenth of those figures in some parts of the world.

One of the most important steps in the development of modern pediatrics was the recognition by physicians of certain fundamental differences between the child and the adult. Conditioned by his state of immaturity, the infant or young child differs from the mature person physiologically, psychologically, immunologically and anatomically. The constant changes in functional patterns incident to growth and development impose different standards for health appraisal and for nutritional, medicinal and other health requirements in the very young. Throughout the wide range of diseases affecting infants and children, the concept of prevention predominates over that of treatment in the mind of the properly trained physician. Fortunately, advances in the basic sciences of nutrition, microbiology, immunology, epidemiology, hygiene and sanitation made it possible for medical practitioners and public health officers to exercise a large measure of control over many of the most devastating physical diseases. Improvements in diagnostic laboratory techniques together with revolutionary developments in chemotherapy and in pediatric surgery reduced the dire effects of certain nonpreventable diseases to a minimum.

The diseases which affect infants and children may be classified according to the nature of their causes, the particular organ systems primarily involved or a combination of these methods. Since pediatrics is based upon the science of growth and development of the individual, the pediatric physician must take into account, so far as is feasible, all conditions that influence the orderly course of these normal processes from the moment of conception throughout the periods of infancy, childhood and adolescence. For example, such determining factors as heredity, prenatal influences (including maternal illness) and injuries incident to the process of birth, explain most cases referred to as diseases of the newborn.

Examples of the hereditary diseases are haemophilia, erythroblastosis foetalis, familial periodic paralysis, certain nervous and mental diseases and a tendency to allergic disorders, such as eczema and bronchial asthma. Of the congenital diseases known to be acquired in utero by the infant as a result of maternal disease, syphilis, certain anomalies (*e.g.*, congenital cataracts and possibly malformations of the heart) and toxoplasmosis are best understood. Prematurity of birth, which constitutes the major cause of an excessively high rate of mortality among infants, is due in the main to foetal anomalies or to impaired health in the mother during her period of gestation. Accidents incident to the birth process, such as asphyxia, brain haemorrhage, fractures and muscular paralyses, may result in immediate death or may be followed by such sequelae as retarded mental development, epilepsy and cerebral palsy.

Serious accidents (including poisoning) which involve children are largely preventable. Yet, as a result of personal carelessness and lack of education in accident prevention, such mishaps were still responsible at mid-century for more deaths and more permanent disabilities than many of the more serious infectious diseases.

Disorders of nutrition, together with the alimentary or enteral diseases, presented the most serious of all problems involved in the care of infants and young children prior to the time when their specific causes were discovered. Later, however, it became possible to prevent the major number of these or to effect a cure in most instances after the disease has been allowed to develop. The nutritional requirements of children for normal growth and development and for normal functioning of the various organ systems of the body differ quantitatively from those of mature men and women. On the basis of age and size, the growing individual needs much more of the essential food substances than do adults. These nutrients are water, protein (essential amino acids), "energy foods" (fats and carbohydrates), vitamins and minerals (calcium, iron, iodine, magnesium, potassium, sodium, phosphorus, chloride, sulphur and the so-called essential trace elements).

Prolonged deficiency of intake in the case of any one or any combination of these essential nutritional factors causes more or less specific symptom complexes. For example, unless water is furnished for young children and infants in required amounts, a state of underhydration ensues. This is manifested by dryness of the skin and mucous membranes, interference with normal circulatory and secretory functions and obvious discomfort from intense thirst. Severe protein privation in the young interferes with building new, and maintaining pre-existing, protoplasm in the living cells of the body and interferes with blood protein formation. Insufficient intake of fats and carbohydrates to satisfy the energy needs of the body likewise limits growth. Of the minerals, calcium and phosphorus are required in optimal amounts for bone formation and for certain other vital cellular functions. Magnesium plays a role in cellular function somewhat similar to that of calcium. Sulphur derived from certain essential amino acids of the diet (methionine and cystine) plays its specific role in the formation of certain all-important substances, such as enzymes, insulin and glutathione. Iodine is essential for synthesis of the hormone thyroxin in the thyroid gland, which is essential for normal growth and development. Iron is an essential constituent of the red blood cell pigment, haemoglobin, which carries oxygen from the lungs to all parts of the body. A deficient intake of this element results in the development of a common form of anaemia. The monovalent elements (namely, sodium, potassium and chloride), which constitute the chief electrolytes in the body fluids, together with the phosphate and bicarbonate ions, serve essential roles in maintaining the normal chemical environment of all living cells, as well as the normal acid-base balance. Alterations in their concentrations in the body fluids, whether caused by certain endocrine disorders, kidney disease, diarrhoea, vomiting or profuse sweating, produce serious illness.

Specific diseases develop from vitamin deficiencies in the diet. Deprivation of vitamin A manifests itself as xerophthalmia and also as "night blindness" arising from disturbed function of the retinal pigments. A variety of disease states occur in infants and growing children deprived of different members of the vitamin B complex. The best known of these are beri beri (caused by lack of thiamine); pellagra (deficiency of niacin); ariboflavinosis (lack of riboflavin) and megaloblastic anaemia of infants (lack of folic, or folinic, acid). Scurvy is caused by inadequate amounts of ascorbic acid (vitamin C) in the diet. Rickets is caused by a deficiency of vitamin D in the diet, unless the skin is exposed directly to ultra-violet light waves. Haemorrhagic disease of the newly born infant is caused by a relative deficiency of vitamin K in the mother's diet during her period of pregnancy. These deficiency diseases rarely occur, however, if the diet contains sufficient amounts of natural foods, including milk, meats, egg yolk, fish liver oils, fresh citrus fruits, green vegetables, salt and water. Cure of existing vitamin deficiency diseases is accomplished most promptly by administration of the missing vitamin in concentrated or synthetic forms.

Many serious diseases of childhood are caused by pathogenic or

parasitic living organisms. Such diseases are classified into general categories according to the type of organism responsible for the particular disease state. For example, there are (1) the bacterial diseases, caused by microscopically visible germs; (2) the viral diseases, caused by specific viruses too small to be seen with ordinary optical microscopes; (3) the rickettsial diseases, caused by an intermediate type of micro-organism; (4) the mycotic diseases, caused by invasion of the tissues by certain plant moulds or mould-like organisms; (5) the animal parasitic diseases, caused by unicellular animal parasites; and (6) the diseases caused by infestation with comparatively larger and more complex animal parasites, such as worms.

The specific infectious diseases in the foregoing categories are too numerous to be discussed in detail here. However, those contagious diseases customarily referred to as "childhood diseases" (measles, mumps, whooping cough, diphtheria, scarlet fever, German measles [or rubella], infantile paralysis, smallpox and chicken pox [*qq.v.*]) deserve special mention. All are known to be caused by specific viruses, excepting diphtheria (*C. diphtheriae*), whooping cough, or pertussis (*H. pertussis*), and scarlet fever (hemolytic streptococcus). Smallpox and whooping cough, like typhoid fever, can be prevented by vaccination. Diphtheria can be prevented by injections of minute amounts of modified diphtheria toxin (toxoid). Treatment of this disease with serum containing antitoxin is usually successful too. Tetanus, or "lockjaw," can likewise be prevented by its specific toxoid and can be treated by tetanus antitoxin. Treatment by means of the antibiotic drugs is successful in whooping cough and scarlet fever. Measles can be prevented temporarily by means of human gamma globulin or convalescent serum.

The common respiratory diseases of infancy and childhood, such as common colds, infantile virus pneumonitis, influenza, atypical pneumonia (all caused by specific viruses) and the bacterial pneumonias (caused by various types of pneumococci, streptococci, staphylococci and *H. influenzae*) are more serious infections in infants than in older children. While attempts to prevent them by vaccination had met with no success by mid-century (except for short periods in the case of influenza), sulfonamide and antibiotic drug therapy had proved to be amazingly effectual in the treatment of those infections caused by bacteria. Unfortunately, such therapeutic agents are far less, if at all, effective in the treatment of respiratory diseases caused by viruses.

Tuberculosis is improved only temporarily by antibiotic drugs. Immunization by attenuated tubercle bacilli (BCG [Bacillus-Calmette Guérin]) remained of uncertain value. Among populations where the disease incidence is comparatively low and where it is feasible to discover and isolate active cases through community-wide programs of tuberculin testing and chest X-ray surveys, attempts to immunize by vaccination would appear to be unnecessary.

Congenital syphilis can be prevented by active antibiotic or arsenical drug treatment of the infected mother before the infant is born or it may be cured in the affected baby or older child by use of these drugs.

Meningitis, lymphadenitis and bacteriemia, caused by meningococci, streptococci, pneumococci, staphylococci, *H. influenzae* and certain other bacteria, can usually be treated successfully with sulfonamide and antibiotic drugs. Infections caused by the gonococcus yield readily to modern chemotherapy also, as do typhoid, typhus and malarial fever.

Many of the congenital malformations of the heart and blood vessels, the gastrointestinal tract, the nervous system and the extremities are amenable to surgical treatment.

The underlying cause of *rheumatic fever* remained unknown, but streptococcic infections accentuate the symptoms. Control of such infections by drugs is beneficial. ACTH and cortisone were still in the experimental stage of development as possible treatments for acute rheumatic fever at mid-20th century. They might prove of great importance in diminishing the incidence of this most common cause of death in children between the ages of 5 and 19.

Advances in endocrinology made possible the successful hormone treatment of such disorders as diabetes mellitus, spontaneous hypoglycaemia, diabetes insipidus, parathyroid tetany, adrenal insufficiency, adrenal hyperactivity, pituitary insufficiency, hypothyroidism and certain diseases of the sex glands.

Mental, emotional and social maladjustments in children tardily gained recognition as having health significance quite comparable with that of the common physical or organic diseases. The functional and organic components of a child's illness may at times be so thoroughly fused as to require use of the special techniques of the psychiatrist for its successful diagnosis and treatment. Appreciation of this fact gave origin to the branch of child psychiatry designated as psychosomatic pediatrics. Prevention of such disorders by consistent application of proper mental hygiene is important.

CHILDREN: PROTECTIVE LAWS. The wide powers of life and death allotted to the head of a family under the *patria potestas* of Roman law were not applied under European feudal systems of law although on the continent of Europe, where the laws were modelled on Roman civil law, stress was placed on the importance of the family and strict controls by curatorship and by the family council were imposed over children, particularly as regards their rights of inheritance to property. The system as developed in England recognized rights of wardship over children enabling a feudal lord, on the death of a tenant leaving an infant heir, to administer the tenant's estate as guardian during the minority of the heir. The guardian was made responsible for waste entailing forfeiture of the land wasted and threefold damages.

Guardianship, whether of the natural parent or other guardian, was recognized as including the right of custody of the child, control of his religious training and education, consent to his marriage, the right of chastisement and the right of enjoyment of his services; and, in addition, control of his estate subject to the use of a sufficient portion for his maintenance, education or training. In England, the court of chancery, in the delegated exercise of the authority of the sovereign as *parens patriae*, assumed wardship if rights of guardianship were abused and applied the property so far as necessary for the maintenance of the child. This jurisdiction was later vested in the chancery division of the high court.

The courts gradually acquired control over abuse of the power of chastisement and heard actions or prosecutions for assault against the person concerned, whether the parent, guardian or teacher or an employer in the case of an apprentice or servant. If attended by fatal results, the charge was for murder or manslaughter.

After 1601, under the English poor law, provision was made for destitute children either in association with their parents or otherwise by the grant of relief by overseers or guardians of the poor. In 1889, power was conferred on poor-law guardians to assume parental rights of control over deserted children and, in 1899, the control was extended to orphans and children of parents who were disabled, in prison or unfit to have them in care. Similar powers were developed in continental countries, particularly in France and later in Belgium and Denmark.

Development proceeded in Great Britain and in Europe, the aims being the prevention of ill-treatment and cruelty, child-life protection, the regulation of dangerous performances, employment restrictions and the compilation of a general children's charter. In England ill-treatment attracting legal punishment consisted originally of blows or threats and was extended to neglect to supply necessaries. The Offences Against the Person act, 1861, imposed punishment for the exposure of infants and for the neglect or ill-treatment of apprentices or servants. The Poor Law Amendment act, 1868, made it an offense for parents to neglect to supply necessaries (*e.g.*, food, lodging, clothing and medical aid) for their children. At the instigation of the National Society for the Prevention of Cruelty to Children, a series of statutes aimed at preventing cruelty to children in their homes was passed in 1889 and progressively extended between 1894 and 1933.

Child-life protection was applied in baby-farming cases in 1897

and 1908 in regard to infants maintained by foster parents for reward, the age limits rising from seven to school-leaving age by the acts of 1932 and 1948. These powers were transferred to the Public Health Acts code in 1936. Penalties for the employment of children up to the age of 16 in dangerous performances were imposed by the statutes of 1879, 1897 and 1932. Restrictions on the employment of children in casual occupations and amusements were imposed in 1903 and extended by the Education acts of 1918 and 1921 and the Children act of 1932. The employment of children between 9 A.M. and 6 P.M. or in injurious work or in street trading was prohibited and local authorities were enabled to make regulative bylaws.

A series of children's charters commencing in 1908 controlled the sale of tobacco and the exclusion of children from licensed bars, and introduced supervision by probation officers and other fit persons, detention in industrial or reformatory schools and the hearing of charges in juvenile courts. The Children and Young Persons act of 1932 extended the control to children in need of care and protection and introduced inspection of voluntary homes by the secretary of state. The statutes were consolidated in 1933. After investigation by the Curtis committee of 1946, the act of 1948 placed on local authorities responsibility for the care of children deprived of normal home life, enlarged their powers of assumption of parental rights over children in their care, and increased their responsibility to act as fit persons at the request of the courts.

MODERN BRITISH LAW

This can be examined under six main heads; viz., legal status, care of children in special categories, protection, welfare, employment and court proceedings.

Legal Status.—Guardianship is regulated by the acts of 1886 and 1925, dealing with control of the person of the child, including custody, training and education. Control of the child's estate is usually vested in trustees during the minority of the child. Affiliation orders may be made against the putative father of an illegitimate child and the child may be legitimated under an act of 1926 by the subsequent marriage of its parents with entitlement to property rights as if born legitimate. The adoption of children is governed by the act of 1950, preventing exploitation of the child and securing its supervision by the local authority during a probationary period. On adoption, the child loses succession rights in the old family and acquires corresponding rights in the new one.

Care of Children in Special Categories.—This is prescribed for five categories of children; viz., according to whether they are deprived of normal home life, in need of care and protection, beyond parental control, handicapped in mind or body, or suffering from mental illness (whether mental deficiency or insanity). The care of these children is shared by local authorities, voluntary organizations and state institutions. The children are either boarded out with foster parents or housed in special homes or institutions. Voluntary institutions are controlled by the secretary of state. Children suffering from mental illness are treated mainly in hospitals provided by the minister of health and the compulsory detention of such children is supervised by the board of control, specially appointed to protect the liberty of the subject.

Children deprived of normal home life, whether orphaned, abandoned or neglected, are committed to the care of local authorities who may in suitable cases assume parental rights. Care may last until the child reaches the age of 18 and may be extended to 21 if necessary. Maintenance contributions are recoverable from parents.

Children in need of care and protection, if under 17, may be brought before the juvenile courts (Children and Young Persons act, 1933). They include children falling into bad associations through lack of parental care and the victims of violence or immorality. Any such child may be sent to an approved school or committed to the care of a probation officer or other fit person. Special medical or other treatment may be recommended.

Children beyond control of their parents or guardians, if under 17, may be brought before the juvenile courts and dealt with like children in need of protection. If they are already in the care of a local authority, they can be sent to approved schools on the order of the juvenile court.

Handicapped children suffering from disability of mind or body can, under the Education act, 1944, be provided by the local authorities with treatment in special schools. This applies to pupils who are blind or deaf or partially so, delicate, diabetic, educationally subnormal, maladjusted, physically handicapped or defective in speech. Medical examination may be enforced and so may attendance at the special school selected until the age of 16. Further assistance between the ages of 16 and 21 is given by the local authority under the National Assistance act, 1948, in the form of provision of work at home or elsewhere and rehabilitation facilities.

Children who are mentally ill receive treatment under the Mental Deficiency acts, 1913 to 1938, the Lunacy and Mental Treatment acts, 1890 to 1930, and the acts relating to criminal lunatics. Treatment of a defective includes supervision in his home or care in an institution, including detention under the order of the judicial authority or the secretary of state. Insane children are treated at out-patient child guidance clinics provided by regional hospital boards and centres provided by local education authorities. In-patient treatment is provided in general or mental hospitals. At a mental hospital, the child may be treated as a voluntary or temporary patient under the Mental Treatment act, 1930. If a reception order is made by a justice of the peace, after certification under the Lunacy acts, the child is detained in a mental or registered hospital or a licensed home.

Protection.—Children maintained for reward apart from their parents are regulated by part VII of the Public Health act, 1936, and part XIII of the Public Health (London) act, 1936, as amended by the Children act, 1948. The protection extends until the age of 15 but may be extended to the age of 18. Local authority visitors inspect the homes of the children and give directions as to their health and care. The local authorities may regulate the number of children kept in the homes and apply to the court for orders of removal of children from unsatisfactory premises to places of safety. Under the Nurseries and Child-Minders Regulation act, 1948, nurseries and child-minders are regulated by local health authorities who keep registers of children looked after for the day or for any longer period not exceeding six days, issue certificates of registration and inspect the premises and the children therein and the arrangements for their welfare. Registration may be refused if the child-minder is unfit to look after children or if the premises are unfit for their reception.

Offenses against children, including cruelty or exposure to moral or physical danger, are regulated by part I of the Children and Young Persons act, 1933. Causing suffering or injury to health is punishable by fine or imprisonment. Other offenses include the causing of seduction, prostitution or begging, the sale of intoxicants, presence or employment in licensed premises, taking articles in pawn from children and exposing infants under seven to the risk of burns. Attendants must be provided where large numbers of children attend entertainments. Assault, rape and abduction are dealt with under the Offences against the Person act, 1861, and protection from prostitution and sexual offenses is ensured under the Criminal Law Amendment act, 1885. Incest is punishable under the Punishment of Incest act, 1908.

Maintenance allowances are payable in respect of children under the state schemes set up under the Family Allowances act, 1945, the National Insurance act, 1946, and the National Assistance act, 1948.

Employment is regulated by part II of the Children and Young Persons act, 1933, ss.58 to 60 of the Education act, 1944, and the acts relating to factories, shops and mines. The restrictions relate to hours of employment, employment while of school age, intervals for meals and rest and holidays. Bylaws may be made by the local education authorities and control is exercised over street trading and entertainments.

Criminal Proceedings.—Various rules protect children as regards these proceedings, including their separation from adults, the granting of bail, the notification of proceedings to parents, guardians and local authorities and the presence of children during

court trials. Most charges against children are heard in juvenile courts and detention is usually prescribed in places other than prisons.

CONTINENTAL DEVELOPMENTS

Towards the end of the 19th century, the importance of child welfare increased in several European countries owing to a fall in the birth rate. In France, premiums were granted for large families (of four or more children). Medical attendance before and after childbirth was made available for the poorer classes and women were allotted rest allowances after childbirth. Employers co-operated in arranging free medical attention for mothers and infants. Breast-feeding and milk distributing centres were provided. Institutions were provided for destitute children by the public assistance scheme. Regulation of employment and special courts for juveniles were established. Similar provision was made in Belgium by the *Oeuvre Nationale de l'Enfance* (an independent public agency assisted by state grants) and the Office for the Protection of Children (under the ministry of justice). In Denmark, child welfare was fostered on public-assistance lines in 1933, and in 1939 maternity aid institutions were established. The Netherlands relied for similar services on private societies (the Green Cross and the White and Yellow Cross) assisted by state grants. Progress in Norway was slower owing to the lack of constitutional powers covering social welfare. In Sweden, social family measures limited in scope were enacted to combat the decline in population.

Progress in child protection received a setback in World War I, which was followed by an effort to restore the previous standards. Co-operation between the nations was secured through the League of Nations and the International Labour office, resulting in international conventions to protect mothers and children, particularly as regards their employment, and to control prostitution. World War II had catastrophic consequences caused by the disruption of families, the problem of refugees and the plight of homeless and undernourished children. Under the auspices of the United Nations an International Children's Emergency fund was created.

In France after World War II the act of 1945 established maternal and child welfare services as part of the public health service of each departmental area. Children deprived of family support were placed under supervision or transferred to state guardianship. Milk distribution to children was secured. Services for defective and delinquent children were improved. Homes and approved schools were provided by the *Direction de l'Education surveillée* under the minister of justice. Agencies for social security and family allowances were operated.

In Belgium the older services were reinstated and measures taken for the health and care of young workers. Similar action was taken in Denmark and the Netherlands after World War II. Norway modernized its statutes concerning child protection and welfare and set up a central organization. Family allowances were introduced. Sweden improved its maternity services, adopted family allowances, set up compulsory sickness insurance and formed child welfare boards in most towns to supervise private and municipal welfare institutions.

UNITED STATES

The tendency of U.S. law has been to enlarge the rights of the child and the measure of protection afforded to him against ill-usage, exploitation and conditions affecting his health, morals and general well-being. While the laws of the various states and the judicial decisions interpreting them differ in details, certain general principles were quite widely accepted by mid-20th century.

The first duty of the parents of children is to provide them with support. This obligation rests principally upon the father but the mother is required to do so upon the death of the father. The Social Security Act of 1935, with its federal subsidy of aid to dependent children (A.D.C.), recognized the difficulties a widow might have in supporting her child and also giving it the necessary care and supervision. Any relative of first or second degree providing care for a child and satisfying the legal test for dependency was made eligible for A.D.C., which was more inclusive than the mothers' pension laws operative in most of the states before 1935.

The father of stepchildren is not obligated to provide for them unless he voluntarily undertakes to do so. In the case of an illegitimate child, the mother is liable for its support, and in some states she and her child are eligible for A.D.C. The father may be required to provide support if his paternity has been legally adjudged or if he voluntarily acknowledges it and assumes the duty of support. The precise extent of the duty of support is determined by the law of the particular jurisdiction. Generally it includes food, shelter, clothing, medical care and education. Compulsory education laws require the attendance of children at school and impose a penalty upon the parents for noncompliance. At the same time, child labour laws prohibit the employment of the child during the time when he is required to be in school or in dangerous occupations.

Generally speaking, the father has the control and custody of the child and he may determine where it shall live although the modern tendency is to recognize a larger right in the mother as to these matters. Either or both parents may be deprived of custody by conduct harmful to the child. In case of the father's death, the mother assumes full custody and control. An illegitimate child becomes legitimate upon the subsequent marriage of its parents. In a few states, legitimation can be effected through a judicial proceeding instituted for the purpose or through the process of legal adoption. A legitimated child assumes the same relation to the parent or parents as if born in lawful wedlock. Where a child becomes an orphan or where his parents prove to be wholly unfit to care for him properly, he may be committed in a legal proceeding, usually through the juvenile court, to the guardianship of a suitable person, a public welfare agency or a private social agency. Guardians may be appointed either to conserve the property of the child or to provide care and maintenance, or both.

A guardian does not assume the full status of a parent. This relationship is established only through the process of legal adoption by which the child becomes the lawful child of his adoptive parents. The tendency of legislation in the 20th century has been to safeguard adoption proceedings by requiring that the child shall remain in the prospective foster home for a trial period, usually six months, before the proceeding is completed. At mid-20th century such laws existed in 40 states, and agencies commonly required a trial period of one year. In 41 states the law (mandatory in 36 states) provided for a social investigation of the foster home by an official or someone designated by the court and a report presented to the court having jurisdiction of the proceeding as to whether the foster parents are proper persons to adopt the child and their home a suitable one for the purpose.

Because of the abuses arising out of the casual transfer of children from parents to irresponsible people, many states passed laws prohibiting any transfer of parental control except upon a court order; *i.e.*, through guardianship or adoption proceedings or upon order of a juvenile court. Few adoption agencies relied only upon a parent's surrender, even where it had become the only legal requirement. The law in many jurisdictions prohibited the bringing of children into one state from another for purposes of permanent care until after investigation and approval by the authorities of the state to which the child is brought.

In addition to the duty of support the parent must shield the child from evil surroundings and may not impose injury or cruelty upon him. The parent may use physical force to protect the child from danger and, under proper circumstances, to impose reasonable

parental correction. The conduct of any adult which tends to deprave the morals of a child or endanger his health or well-being is punishable as a criminal offense.

The White House Conference on the Care of Dependent Children called by Pres. Theodore Roosevelt in 1909 incorporated among its conclusions the following: "To engage in the work of caring for needy children is to assume a most serious responsibility, and should, therefore, be permitted only to those who are definitely organized for the purpose, who are of suitable character, and who possess, or have reasonable assurance of securing, the funds needed for their support. . . ." This conference and succeeding White House conferences on child welfare in 1919, 1930, 1940 and 1950 emphasized the need for organization and development of a strong department of public welfare in each state with functions to include the licensing of voluntary child-care agencies and institutions and the supervising of similar services wherever operated by cities, counties or the states.

At mid-20th century there was great variation in the state laws for proper care of dependent children and in the administrations of the public welfare departments responsible for enforcing such laws. These variations had been reduced, however, by the provisions of the Social Security act, and the federal grants-in-aid under this act, which first became available in 1936. This act and succeeding annual appropriations by the congress authorized and subsidized the child welfare services as well as aid to dependent children and other forms of public assistance. Child welfare services gave priority to various social services for children in rural areas, and as a result many counties organized such programs in conformity with plans drawn up by state welfare departments, which in turn required approval by the U.S. children's bureau. An important element in the plans was the provision, with federal funds, for professional training for the social workers essential to effective service. Child welfare services include work with delinquent, emotionally disturbed and mentally handicapped children as well as those who are dependent, covering services to children in their own homes as well as in foster homes.

The responsibility for licensing a children's institution, a child-placing agency or a day-care centre usually is carried by the children's division of the state department of public welfare, with the responsibility to license foster homes usually carried by a county department of public welfare. Other public officials who sometimes share in the inspection prerequisite to issuance of a license are public health officers and fire marshals. In some jurisdictions the only license required for a foster home or a day-care centre is issued by the health department.

Laws governing guardianship and custody, administered by local courts, differed greatly at mid-century, though in many states their original characteristics, derived from the English Poor law, had little adaptation to modern social and economic conditions. Indenture of children, though still practised, was widely condemned in the early years of the 20th century. The obsolete laws authorizing indenture in the statutes of most of the older states were repealed, though it was as late as 1946 in Mississippi. The rights of children born out of wedlock were recognized in the revision of legal requirements for birth registration to the extent that in some states a birth card, supplying data needed for enrolment in school and satisfaction of the child labour laws, became the common document issued in lieu of a complete birth certificate. The original record and information about parentage remained available only for restricted use and in the child's interest. Safeguards assuring rights of inheritance to adopted children were developed, especially in preventing hasty and illegal adoptions. Hazards to children of unmarried mothers, comprising the majority of those placed for adoption, still persisted as evidenced by the operation of baby farms and the prevalence of black-market adoptions in which the rights of the child received secondary consideration.

Beginning in 1911, protective legislation for children was markedly accelerated by the work of state commissions for the study and revision of child welfare laws. This movement was no doubt stimulated in part by the British Children Act of 1908, sometimes referred to as the "Children's Magna Charta." While this act was mainly a codification of existing law on the subject, in the process of compilation and revision distinct advance in protective measures was made. The White House Conference on the Care of Dependent Children recommended periodic review and revision of child welfare legislation. In 1911 the first state commission was appointed for this purpose. By mid-century almost all states and the District of Columbia had followed the precedent set by Ohio. Stimulated by the National Commission on Children and Youth appointed during World War II by the U.S. children's bureau, committees and councils in most of the states urged further revision of children's codes. The year 1947, when most of the state legislatures held their biennial sessions, was one of unprecedented activity, one-half of the states then making changes in their adoption laws.

States were influenced after World War II by the Veterans' administration, especially in making more adequate provisions for guardianship of children of veterans.

Large numbers of children became beneficiaries of life insurance carried by their fathers and others became entitled to benefits under old aid and survivors insurance administered by the Federal Security agency.

The National Conference on Prevention and Control of Juvenile Delinquency, held in Washington in 1946 was attended by about 800 officials and professional workers experienced in serving children. Their findings dwelt on the interrelationship of housing, recreation, education, religious training and family relationships and the need for recognition of these forces by the entire community and especially by those who enact and enforce laws and administer training schools for delinquents.

Recommendations pertaining to the protection of children, passed at the Midcentury White House Conference on Children and Youth, held in 1950, included the following:

"That children of migrant and seasonal workers be given all the protections and services available to other children, with special regard to transportation, housing, sanitation, health and educational services, social benefits, and protection under labor laws.

"That standards be developed for juvenile services by police departments.

"That, in accordance with state-wide standards, courts of superior jurisdiction, with judges qualified in the law with an understanding of social and psychological factors, and with qualified probation staff and auxiliary personnel be available for all cases involving children with problems that require court action in rural and urban areas.

"That the preventive and treatment functions of social agencies, police, courts, institutions, and after-care agencies be coordinated so as to insure continuity of service.

"That states and other appropriate public bodies establish and enforce standards covering the employment of youth in all occupations, such standards to include minimum age and wages, as well as hours of work, night work, protection from hazardous occupations and provisions for workmen's compensation; and that, under these conditions, employers in cooperation with labor be urged to provide appropriate work experience for youth on a part-time basis.

"That communities foster cooperative community councils representative of all community interests to study and advance better conditions and opportunities for young workers.

"That citizens be encouraged to support adequate appropriations and qualified staff to administer and enforce basic legislative standards of states, and other appropriate public bodies, covering the employment of youth."

CHILDREN'S BOOKS. Children's "books" in Europe, like other books, were in use before the invention of printing. Such works as *Gesta Romanorum*, the riddles and scholastic exercises of Aelfric and Alcuin, versions of Aesop's *Fables*, etc., were all used by children. They are, however, a piece of social history rather than of specialized literature. The early printed (and ms.) "books of courtesy"—which contained rules of conduct in polite society—are also social documents, and may be set apart with abecedaria, hornbooks, battledores and pure schoolbooks. They lived a changed life later in works like Francis Osborne's *Advice to a Son* (1656), and Chesterfield's *Letters*. With the Reformation, secular books gave way to fierce moral tales which dealt out hell-fire punishment to sinners, as typified by James Janeway's *Token for Children* (1720). But the greatest of all Puritans was one of the first to see that something less stark was needed. John Bunyan's *Book for Boys and Girls; or, Country Rhimes for Children* (1686: later renamed *Divine Emblems*), popular for more than a century, contained rough but kindly "natural history" verses and vigorous "morals."

The Fairy Tale.—Meanwhile, oral tradition was preserving vernacular folklore, destined to be the bedrock of children's literature in the form of fairy stories and versions of the Arthurian and Robin Hood romances. There was no printed version, however, before the crudely printed chapbooks which spread over England in the late 17th and early 18th centuries—the library of Steele's little godson (*Tatler*, No. 95). Here the child found action and romance—the same ingredients which in part accounted for the popularity of *Pilgrim's Progress* (1678), *Robinson Crusoe* (1719) and *Gulliver's Travels* (1726). The fairy tale also invaded England from court—Louis XIV's—when Perrault's *Histoires ou Contes du Temps Passé* (1696 in French, probably 1729 in English; better known as *Mother Goose's Fairy Tales*), and the Comtesse D'Aulnoy's tales (1707) were translated.

This was not enough to make a literature. Other developments were needed. Isaac Watts created one with his moral but technically excellent verses (1715). But the real beginning lay in four volumes and in the personality of one man. A few well-known rhymes had appeared incongruously in severer treatises; but the nursery-rhyme was first thoroughly collected in *Tommy Thumb's Pretty Song Book* (1744), *The Top Book of All, Mother Goose's Melody*, and *Gammer Gurton's Garland* (all ascribed to 1760).

The man was John Newbery, who in 1744 published his first children's book, *The Little Pretty Pocket Book*. Before his death in 1767 this friend of Goldsmith had built up a business which itself lasted into the 20th century, and had founded a new branch of the book trade. There is no space here to enumerate his "pretty gilt toys for girls and boys" (so-called from their gay Dutch-paper bindings). In form (strongly bound, not ill-printed, before long quite tolerably illustrated) as well as in substance, they decided the nature of children's books for three or four generations, even though fashion in expression changed.

The Moral Tale.—Their contents were soon influenced by wider issues than the bookseller probably foresaw. Philosophy and even politics intervened. Maria Edgeworth (1767–1849), the best of all storytellers of this period for children, and her friend Thomas Day (*Sandford and Merton*, 1783–89) deliberately put into nursery tales the doctrines of Rousseau. Arnaud Berquin ("l'ami des enfants") translated Day into French, and was himself translated copiously, with other French writers. Maria Edgeworth's work prepared the way for the freer, more realistic stories of Mrs. D. M. Craik, Mrs. J. H. Ewing, Mrs. Alfred Gatty, Mrs. M. L. Molesworth and Charlotte M. Yonge. The active Quakers (like Priscilla Wakefield) wrote many moral tales. Mrs. Trimmer, remembered for her *Robins* (1786; originally called *Fabulous Histories*), at once combated Jacobinism, on behalf of the church, and desired fairy tales to be suppressed as immoral. Mrs. Sherwood also wished to depose Titania; but her *Fairchild Family* (1818, etc.) remained popular for at least four generations. Ann and Jane Taylor (1804, etc.) of a notable Nonconformist family, put the "cautionary tale" into nimble verses, of which "Twinkle, twinkle, little star" will never die; with them should be associated Elizabeth Turner (1807, etc.). The Lambs were, in a sense, of the same school; Blake is splendidly apart from all tendencies.

The Return of Fantasy.—Fantasy returned in 1806, when 40,000 copies of Roscoe's *Butterfly's Ball* and Mrs. Dorset's *Peacock at Home* were sold. The tide of reaction against "amusement with instruction" came to a head in 1824, when the *German Popular Stories* of the brothers Grimm began to appear in English, with Cruikshank's illustrations. Hans Andersen was translated in 1841, levity (even naughtiness) condoned by Catherine Sinclair in *Holiday House* (1839), and absurdity made sublime by Edward Lear's *Book of Nonsense* (1846).

This new freedom infected even "Felix Summerly" (Sir Henry Cole, an adviser of the prince consort) who introduced the Seven Champions and other fabulous monsters into his chaste and well-produced *Home Treasury*. There followed what may be called the Parley epoch, in which a number of Peter Parleys—the chief an American, S. G. Goodrich—vied in amassing instruction in easy-going form.

In 1865 or 1866 and in 1872 appeared the greatest of all children's books, the two *Alice* volumes of Lewis Carroll (C. L. Dodgson), with whom is indissolubly associated John Tenniel. These inspired, finely imaginative tales finally routed didacticism and moralizing and passed at once not only into the affections of the whole English-speaking world, but also into its arsenal of quotations. They made possible the success of the good modern fairy tale (the poor one is a perpetual trap for inexperienced writers), like those of Kingsley, George Macdonald and Mrs. Molesworth; of such books as Mrs. Ewing's *Lob-lie-by-the-Fire;* of the magical *Peter Pan* (1911); of such delicate modern art as A. A. Milne's *Winnie-the-Pooh* (1926) and Kenneth Grahame's *Wind in the Willows* (1908); John Masefield's *Midnight Folk* (1927) and the writings of Walter De La Mare.

The animal story, a prominent feature of the 20th century, had its beginnings in the late 18th century; but the animals remained characterless until *Black Beauty* appeared (1877) and Kipling was inspired to write his *Jungle Books* (1894–95). Animal stories of the more fanciful type are closely allied to the fairy tale; Beatrix Potter's excellent little books (1902–30), illustrated with charm and delicacy by the author herself, are outstanding examples.

Other developments were the adventure story (a parallel growth to the adult novel), firmly established by *Coral Island* (1857); the boys' school story, notably *Tom Brown's Schooldays* (1856) and *Stalky and Co.* (1899) and its sentimental counterpart for girls; Edith Nesbit's own particular blend of fantasy and reality; and the appearance in the latter half of the 19th century of literature of appeal to the older child, as opposed to the "babies'" nursery stories of earlier days.

Illustrations were counted a necessity in children's books from the beginning but did not reach satisfactory artistic standards until the work of Bewick and Blake appeared in the 18th century. Walter Crane (1845–1915), Kate Greenaway (1846–1901) and Randolph Caldecott (1846–86) contributed outstanding work in line and colour. Modern colour lithography made possible the reproduction of fine work by Kathleen Hale (in the *Orlando* series), Clarke Hutton and Edward Ardizzone (all 20th century).

During the 20th century a new type of children's book has developed; nonfiction which seeks not to educate, but to interest, and in so doing, often imparts more knowledge than a text book. The articles in Arthur Mee's *Children's Encyclopedia* (1906) were a landmark in this type of literature. The major development, however, has been in children's fiction. With the publication of Arthur Ransome's *Swallows and Amazons* (1930) emerged the realistic children's novel, with good characterization and plot

within the bounds of possibility. Written in easy, colloquial style and peopled with lively children, creators of their own fun, Ransome's works have many able imitators.

The school story has given way to the family story, such as Eve Garnett's *Family from One End Street* (1937) and many series of holiday adventures. Novels have been written especially for the young adolescent; for example, career stories such as Richard Armstrong's *Sea Change* (1948).

UNITED STATES

Colonial Period to 1800.—The Puritan exodus from the old world which began with the landing of the *Mayflower* in 1620, brought to American shores "the people of a book, and that book was the Bible." This meant a people so deeply concerned with religion that their first responsibility to their children was to indoctrinate them with their beliefs. As early as 1632 there are references to hornbooks, those little paddles with an alphabet and the Lord's prayer pasted on, but the first real book for children published in the new world was John Cotton's *Spiritual Milk Drawn Out of the Breasts of Both Testaments, Chiefly for the Spiritual Nourishment of Boston Babes in Either England* (1646). It was an example of theological didacticism, for the instruction of "babes," with the intent of stiffening their resistance to sin by lurid pictures of hell and only faint hopes of heaven. *Spiritual Milk* was followed by the famous *New England Primer*, printed in Boston, sometime before 1690. It began with the alphabet "In Adam's fall/We sinned all" and as the years went by and new editions succeeded each other, its theology grew steadily grimmer. But by the time the American Revolution began, theology had diminished in favour of appropriate patriotic sentiments. *Spiritual Milk* and the *Primer* were followed by some terrifying booklets dealing with the "joyful deaths" of pious children. These must have induced more night terrors than love of reading, but dreadful as they were, they bear witness to the Puritans' recognition of books as the tools of learning.

In Worcester and Boston, Isaiah Thomas (1749–1831) imported and later pirated his own editions of John Newbery's popular books for children. The most famous of these was the immortal *Mother Goose* (1785), the edition of nursery rhymes Oliver Goldsmith is supposed to have compiled. In New York city, another printer, Hugh Gaine (1726 or 1727–1807), brought out *The Wonderful Life and Surprising Confessions of the Renowned Hero Robinson Crusoe* (1775). Also in circulation were *Aesop's Fables in Verse, Watts' Divine Songs for Children*, and little chapbook versions of such fairy tales as "Cinderella" and "Tom Thumb." So perhaps small Puritans, struggling with the harrowing *Spiritual Milk*, may have been heartened now and then by stray glimpses of happier reading matter.

Nineteenth Century.—In 1831, a little book called *Mary Lothrop Who Died in Boston* made its appearance and seems to have terminated the morbid emphasis on the brevity of a child's life. In 1819 Washington Irving's *Sketch Book* appeared with that still popular fairy tale of the new world, "Rip Van Winkle." Then came those remarkable books by James Fenimore Cooper of which *The Last of the Mohicans* (1826) and *The Deerslayer* (1841) became the most popular both in the U.S. and Europe. His heroic Indians and Irving's fantasy gave children their first taste of native romanticism and good writing.

Then earnestness set in, this time in the form of educational didacticism which pursued children through one long series of books after another. Samuel Goodrich, who wrote under the name of Peter Parley, turned out about five or six books a year; *Tales of Peter Parley about America* (1827) was typical. The books contained laudatory biographies, bits of science, history and geography, amazingly dull in style but popular both in England and the United States. Even more popular were the innumerable books of Jacob Abbott. By 1834 his *Rollo* books were underway. *Rollo Learning to Talk* was followed by 28 volumes which accompanied Rollo around the world with a steady barrage of information.

Book series were momentarily interrupted by Susan Warner's Sunday school best seller, *The Wide, Wide World* (1850), and a few years later, *Queechy*. Girls liked these books and the tears shed by the orphaned heroines were matched by the tears of young readers. Then, back to the series again, with the first appearance of the priggish *Elsie Dinsmore* (1868) by Martha Finley (pseudonym for Farquharson) who carried her heroine through 26 volumes. Elsie's sentimentality was paralleled by stereotyped success stories for boys written by Horatio Alger. His *Ragged Dick* (1867), in the rags-to-riches pattern was a typical example. Two entertaining series of stories about normal children and family life were *The Five Little Peppers and How They Grew* (1881) by Margaret Sidney, pseudonym of Harriet Mulford Lothrop, and the well written books by Laura Richards—*Queen Hildegarde* (1889) and *The Three Margarets* (1897).

In the field of verse, Clement Moore's ballad, "A Visit from St. Nicholas" (1822) delighted children. Some of the better poems of Eugene Field (1850–95) and James Whitcomb Riley (1849–1916) are still to be found in modern anthologies and Laura Richards' *In My Nursery* (1890) began the gay nonsense verses which she continued to write in the next century. *The Brownies, Their Book* (1887), by Palmer Cox, launched a series of picture stories in verse about the antics of a band of brownies. These elves were individualized and favourite characters were the Dude or the Cowboy or the Policeman, perhaps.

Suddenly among those minor works, great books appeared. Nathaniel Hawthorne's *A Wonder-Book For Boys and Girls* (1852) and *Tanglewood Tales* (1853) reduced myth to child's size but were full of the enchantment of wonderful storytelling. Mary Mapes Dodge's *Hans Brinker or the Silver Skates* (1865) charmed children with its story of Holland. Louisa M. Alcott's *Little Women* (1868) has been so beloved by girls that it has appeared in one new edition after another. It gave girls an intimate picture of a loving, struggling family, with memorable characterizations of four sisters, and a happy element of romance. For boys there were two major books—*The Adventures of Tom Sawyer* (1876) and *The Adventures of Huckleberry Finn* (1884), by Mark Twain (pseudonym for Samuel L. Clemens). The heroes, like Clemens himself, knew everyone in the village from the town drunkards to the deacons of the church. Adventure, humour and authentic portrayals of boy nature made these books unrivalled Americana and good literature.

In different vein another great originator, Howard Pyle, retold the epics. Of these, his *Merry Adventures of Robin Hood* (1883), with Pyle's own illustrations, remained over the years the best version of that hero tale. His stories in folklore style came next —*Pepper and Salt* (1887) and *Wonder Clock* (1887). His two books on mediaeval times, *Otto of the Silver Hand* (1888) and *Men of Iron* (1891) set high standards for historical fiction. In 1883 Joel Chandler Harris' *Nights with Uncle Remus* introduced children to the rich humour of American Negro folk tales and in 1880 Lucretia Hale's droll *The Peterkin Papers* set children and adults to chuckling.

So the 19th century progressed from religious and educational didacticism, stereotypes and sentimentality to sound folklore, myth, and epics, drolls, realistic stories of family life, unsurpassed historical fiction and Americana. Nor were these books the product of ordinary writers condescending to the juvenile field. They were created by men and women of established literary reputations. Their work and that of writers abroad lifted children's books from the trivial to an area of literature worthy of respect and study.

Twentieth Century.—The notable books with which the 19th century closed were forerunners of a phenomenal flood of books for children in the 20th century. Causes are matters of speculation. The rise of kindergartens, and later nursery schools, brought with them a new concern for the needs of young children. The development of laboratory psychology, psychiatry and adult education fostered a broader knowledge of childhood and adolescence. Innumerable research studies in reading skills led to a new evaluation of books. By 1900 children's rooms were established in public libraries and by 1940 libraries began to appear in elementary schools. Before 1915 library and teacher training schools had added courses in children's literature to their curriculums. Between 1920 and 1930, scholarly reviews of children's books were underway. Children's Book Week was a nation-wide observance by 1919 and *The Horn Book Magazine,* devoted to children's literature, was launched in 1924. In 1922 Frederick Melcher, editor of *Publishers' Weekly,* established the Newbery Medal, an annual award for the most distinguished literature for children written in this country. The Caldecott award for the best picture book was added in 1938. Both called attention to the fact that in books for children there can and should be elements of distinction.

Picture stories attained distinction with Wanda Gag's *Millions of Cats* (1928), told and illustrated in folk tale style. She was an innovator few have equalled. Marjorie Flack's *Angus and the Ducks* (1930) began a series of dog stories for the nursery age. *Make Way for the Ducklings* (1941) by Robert McCloskey and *Little House* (1942) by Virginia Burton, both won Caldecott medals. Maude and Miska Petersham, Berta and Elmer Hader, Ingri and Edgar d'Aulaire, Leo Politi, Will Lipkind and Nicolas Mordvinoff, Roger Duvoisin and others made picture stories beloved by children everywhere.

Folk and Fanciful Tales.—In 1909 Kate Douglas Wiggin and Nora Archibald Smith compiled a fine edition of *The Arabian Nights.* But it was Gudrun Thorne-Thomsen's collection of Norse tales, *East o' the Sun and West o' the Moon* (1912) together with her storytelling that started a wave of interest in European folk tales. Major compilations were made by Padraic Colum, Ruth Sawyer, James Cloyd Bowman, Parker Fillmore and others. In 1924 Esther Shephard made the first collection of the American tall tale stories, *Paul Bunyan,* the lumberjack hero. To these James Cloyd Bowman added *Pecos Bill, the Greatest Cowboy of All Time* (1937). Glen Rounds, Richard Chase, Anne Malcolmson and Irwin Shapiro also contributed to the store of folk tales of the United States.

Modern fanciful tales were few at the beginning of the century but soon included such original inventions as Carl Sandburg's *Rootabaga Stories* (1922), Dr. Seuss' (pseudonym for Theodor Seuss Geisel) *500 Hats for Bartholomew Cubbins* (1938) and the same year, *Mr. Popper's Penguins* by Richard and Florence Atwater. The *Cat Who Went to Heaven* (1930) by Elizabeth Coatsworth, *Rabbit Hill* (1944) by Robert Lawson, *Miss Hickory* (1946) by Carolyn Bailey and *Twenty-One Balloons* (1947) by William Pène du Bois, all won Newbery medals, and E. B. White's *Charlotte's Web* (1952) had equal originality and distinction. These were examples of fantasy without benefit of fairies!

Realism.—Realistic animal stories were increasingly popular after the publication of Ernest Thompson Seton's *Wild Animals I Have Known* (1898) and Jack London's *The Call of the Wild* (1903). These set new standards of fidelity to animal lore, well maintained with two Newbery winners—*Smoky* (1925) by Will James and *King of the Wind* (1948) by Marguerite Henry. *Kildee House* (1948) by Robert Montgomery and books by Jim Kjelgaard, Joseph Lippincott, John and Jean George afford outstanding examples of authentic animal stories.

The world of here and now came alive for 20th-century children with Kate Douglas Wiggin's *Rebecca of Sunnybrook Farm* (1903) and Frances Hodgson Burnett's *The Secret Garden* (1909). Both books developed strongly individualized child characters and unusual story interest. After those books, realism developed along many lines. Stories of everyday children, earnestly doing their best but finding themselves in ludicrous situations were Eleanor Estes' *The Moffats* (1941–43) and Robert McCloskey's *Homer Price* (1943). The regional books of Lois Lenski, such as her *Strawberry Girl* (1945; Newbery Medal) and Doris Gates' *Blue Willow* (1940), gave children serious but appealing pictures of underprivileged families. Grace Moon and Ann Nolan Clark wrote authentic stories of American Indians. Other racial and religious minorities were sympathetically presented by Marguerite De Angeli, Mabel Leigh Hunt and Florence Crannell Means. Popular stories about peoples of other countries were written by Kate Seredy, Armstrong Sperry, Monica Shannon and Elizabeth Lewis, all winners of Newbery Medals.

Historical Fiction and Biography merged in children's literature and included some of the strongest books the United States had produced. Laura Richards' *Florence Nightingale, the Angel of the Crimea* (1909) and Albert Bigelow Paine's *Girl in White Armor* (1927) were vigorous beginnings. The latter was an unforgettable picture of Joan of Arc. Hendrick Van Loon's *Story of Mankind* (1925), Newbery winner, gave further impetus to vivid biography which Elizabeth Janet Gray, James Daugherty, Clara Ingram Judson, Genevive Foster and the *The Landmark Books* further illumined. Cornelia Meigs' *Master Simon's Garden* (1916) launched historical fiction that was authentic, well-written, and with a lasting message for the modern world. Rachel Field's historical novel, *Calico Bush* (1931), was her best book and Esther Forbes' Newbery winner, *Johnny Tremain* (1943), was rated as one of America's greatest juvenile books. Laura Ingalls Wilder's splendid eight volume saga of a pioneer family began with *Little House in the Big Woods* (1932). Walter Edmonds, Elizabeth Coatsworth, Stephen Meader and Rebecca Caudill also made notable contributions to this field.

Poetry for children in the United States developed a fresh, native melody and an awareness of the child's interests. The poets of childhood used successfully those qualities of poetry that most delight a child and so prepare him for an appreciation of adult poetry later on *Under the Tree* (1922) by Elizabeth Madox Roberts was the voice of a creative artist speaking as a child. *Taxis and Toadstools* (1926) by Rachel Field, presented a child's-eye view of city and country. Vachel Lindsay's *Johnny Appleseed and Other Poems* (1928) and Carl Sandburg's *Early Moon* (1930) introduced free verse and a vigorous masculine note to children's poetry. The southwest, with its Indians and deserts came alive in Mary Austin's *Children Sing in the Far West* (1928) and Rosemary and Stephen Benét enlivened American history with their penetrating vignettes of famous heroes in *The Book of Americans* (1933). Harry Behn's *Little Hill* (1949) had child appeal and lyric charm. Moreover, such poets as Edna St. Vincent Millay, Sara Teasdale and others wrote occasional poems for children which added to the child's store of authentic poetry.

CHILDREN'S COURTS or JUVENILE COURTS, a special system of tribunals for dealing with juvenile offenders, which has found its widest development in the United States. The earliest trace of such institutions is however contained in a Swiss ordinance of the year 1862. In 1869 Massachusetts adopted the same principle when a plan was introduced of hearing charges against children separately and apart from the ordinary business of the lesser tribunals. The system of probation, by which children were handed over to the kindly care and guardianship of an appointed officer and thus escaped legal repression, was created about the same time in Boston, Mass., and produced excellent results. The probation officer is present at the judge's side when he decides a case, and is given charge of the offender, whom he takes by the hand either at his parent's residence or at school, and continually supervises, having power if necessary to bring him again before the judge. The example of Massachusetts in due course influenced other countries, and especially the British colony of South Australia, where a state children's department was created at Adelaide in 1895, and three years later a juvenile court

was opened there for the trial of persons under 18 and was conducted with great success, though the system of probation officers was not introduced.

The movement when once fully appreciated went ahead very rapidly and most civilized countries throughout the world have now adopted it. France, Germany, Spain, Holland, Belgium, Austria, Hungary, Sweden and Switzerland have all established these courts. In Paris the splendid work of M. Henri Rollet secured the foundation of such a court in 1912, while the Berlin children's court, established in 1923, is a particularly well worked and efficient one. Italy, Czechoslovakia, Yugoslavia, Poland, Bulgaria and Esthonia are making arrangements not yet completed. Norway, Denmark and Finland deal with children's cases under a special code, while the Soviet Government of Russia entrusts the whole matter to the education authorities. In India, Madras secured a Children Act under which the powers conferred were to be exercised "only by a juvenile court." Bengal followed in 1922, and the Indian Government are now striving zealously to establish the principle throughout India. Australia, Canada, South Africa and New Zealand all have children's courts in good working order, and in Melbourne, Sydney, Cape Town and Johannesburg they are particularly flourishing. Japan introduced a very interesting system for dealing with offenders under the age of 18 in juvenile courts in the year 1922, Brazil in 1923 and the Argentine in 1924. Amsterdam has tried the new experiment of instituting a police service especially for children, many of its members being women. The republic of Colombia insists that all juvenile offenders shall be examined by a medical man who is present in court as an assessor.

In England the Home Office recommended London police magistrates to keep children's cases separate from those of adults; the same practice or something analogous obtained in many county boroughs, such as Bath, Birmingham, Bristol, Bolton, Bradford, Hull, Manchester, Walsall, Halifax and others, and the Children Act, 1908, definitely established children's courts. This act enacted that courts of summary jurisdiction when hearing charges, etc., against children or young persons should, unless the child or young person is charged jointly with an adult, sit in a different building or room from that in which the ordinary sittings of the court are held, or on different days or at different times. Furthermore, provision must be made for preventing persons apparently under the age of 16 years whilst being conveyed to or from court, or whilst waiting before or after their attendance in court, from associating with adults, unless such adults are charged jointly with them. The act prohibits any persons other than members and officers of the court, the parties to the case, their solicitors, counsel and other persons directly concerned in the case, from being present in a juvenile court, except by leave of the court. Bona-fide press representatives are also excepted. The main object of the whole system is to keep the child, the embryonic offender who has probably erred from ignorance or the pressure of circumstances or misfortune, altogether free from the taint or contagion that attaches to criminal proceedings. The moral atmosphere of a legal tribunal is injurious to the youthful mind, and children who appear before a bench, whether as accused or as witness, gain a contemptuous familiarity with legal processes.

The most beneficial action of the children's court comes from its association with the system of personal guardianship and close supervision exercised by the probation officers, official and voluntary. Where the intervention of the newly constituted tribunal can not only save the child from evil association when first arrested, but can rescue him without condemnation and committal to prison, its functions may be relied upon to diminish crime by cutting it off at the source. Much depends upon the quality and temperament of the presiding authority. Where a judge with special aptitude can be appointed, firm, sympathetic, tactful and able to gain the confidence of those brought before him, he may do great good by dealing with each individual and not merely with his offence, realizing that the court does not exist to condemn but to strengthen and give a fresh chance. Where the children's court is only a branch of the existing jurisdiction worked by the regular magistrate or judge fulfilling his ordinary functions and not specially chosen, the beneficial results are not so noticeable. The Juvenile Courts (Metropolis) Act, 1920, has given legislative authority to this principle by enacting that the home secretary in selecting as presidents of such courts certain metropolitan magistrates "shall have regard to their previous experience and their special qualifications for dealing with cases of juvenile offenders."

In view of the fact that about 50% of regular criminals begin a life of crime when under 21 years of age, the importance of the juvenile courts can hardly be exaggerated. Rightly, sympathetically and firmly dealt with whilst still young, the vast majority of these potential criminals would become good citizens of the State. Bad surroundings, evil companions, undesirable parents, mental and physical deficiencies and various psychological causes are responsible for most juvenile delinquency. The responsibility for discovering, removing or eliminating these causes rests with the children's courts, and too much care, time and effort cannot be expended in the carrying out of this work. The younger the offender, the greater is the need for efficient diagnosis of the underlying causes of his wrongdoing. That the Home Office is fully alive to this necessity is shown by the very careful report of the juvenile offenders committee published in 1927. Valuable as probation has proved itself to be in the adult courts, it is of even greater value in the children's courts. The legislature, recognizing this importance in all courts, has greatly strengthened the system by the passing of the Criminal Justice Act, 1925, the first ten sections of which deal exclusively with the question of probation. It enacts that "one or more probation officers shall be appointed for every probation area," but in country districts combined areas may be created. The secretary of State is empowered to make rules (which have now been promulgated and are in force) governing the appointment, qualifications and salaries of probation officers and the constitution, procedure, powers and duties of the probation committees. *See* also CHILDREN: PROTECTIVE LAWS; INFANT; JUVENILE DELINQUENCY.

UNITED STATES

Legal and Historical Background.—The juvenile court as a distinct organization originated in America but takes its root in legal and philosophical assumptions current in the 19th century. Its immediate aim was to preserve children from the abuses of criminal procedure. Its principles involve a revolutionary change of attitude. The 17th and 18th centuries record great severities. A child of ten who confessed to killing his bed-fellow was punished with the death penalty, because "sparing of this boy simply on account of his tender years might be of dangerous consequences to the public by propagating a notion that children might commit such atrocious crimes with impunity." "In 1828 in New Jersey, a boy of 13 was hanged for murder committed when he was 12. A survey in Illinois revealed that in 1898 575 children between 10 and 16, were confined in the Chicago jail, and 1,983 boys were committed to city prison." Similar conditions existed in every part of the United States.

At first there was no thought of modifying court procedure. The idea was stressed that after conviction the confinement should be apart from adult criminals. Rise of children's reformatories made this possible in New York (1825), Pennsylvania (1828), and Massachusetts (1847). There was also some provision for separate hearings for children, and for probation in Massachusetts between 1870 and 1880, and in New York in 1892. In 1899 the first juvenile court was organized (Cook county, Chicago, Ill.). It brought under one jurisdiction children who violated laws and dependent children, provided identical procedure for both, established probation, decreed that adjudication be deemed not a conviction of crime, but the placing of the child in the relation of ward to the State. The care for the delinquent child was to "approximate as nearly as may be that which should have been given by the parents." Instead of warrant of arrest, examination by a police judge, bail, indictment, jury trial and sentence, there was substituted complaint, investigation by probation officer, petition, informal hearing and commitment. Fines, imprisonment and penal treatment were abolished. The movement spread with rapidity. By

1904 ten States had juvenile courts; after the first ten years, 20 States and the District of Columbia; by 1914, 30 States; and in 1928 only two States (Wyoming and Maine) were without juvenile courts.

This rapid expansion, without trained personnel, led to a period of critical inquiry. The State supreme courts, however, have upheld the constitutionality of the original statutes. Juvenile court ideals have not been applied throughout the rural districts and small towns. In 1918 the Children's Bureau, Washington, D.C., estimated that of 175,000 cases of children in the U.S. courts, approximately only 50,000 went before courts adapted to handle them.

The juvenile court principle is, first, that the child is not an ungrown adult, but a distinct being, physically, mentally, emotionally and socially; the child's response to life is different; secondly, that the State should not proceed against the child as prosecutor, but exercise the chancery power of *parens patriae* to protect the child.

Age-limits.—The legal meaning of the term "child" is defined by statute, which limits the age of criminal responsibility. Under the English common law, no child under seven was held responsible for crime. Belgium in recent years has raised this to 16, the period *sans discernment*. In the United States the tendency is to increase it to 18 and even 21 (excepting offences punishable by death or life-imprisonment). In approximately one-third of the States jurisdiction of the juvenile court extends to children under 16, in one-third to children under 17, and in the remaining third to children under 18 and above.

It is argued that the older child is entitled to trial by jury, and will not be injured by penal treatment. There is however scientific evidence that the child is not capable of complete integration, or maturation, until 21 or beyond, a belief crystallized in the practice of civilized countries to keep him under legal disabilities as regards contract, voting and marriage until age of majority is reached. In the opinion of many experts it is only a question of time until the juvenile court age-limit will be the same as the recognized age of majority.

Treatment.—The psychological importance of the first offence cannot be overstated. Police methods of apprehension and investigation should be eliminated. The child's court hearing in the better sort of American courts is informal. A well trained juvenile court judge does not proceed to disposal unaided. He seeks the wisdom of the clinic and the social worker. If the child has constructive possibilities he may safely be placed on probation.

Foster homes are used in some parts of America for the placement of delinquent children from unfit homes. Maintenance is supplied by public or private agencies. Correctional institutions are used for cases where an extended period of training is indicated, or where the child is under physical or mental handicaps. Some correctional institutions have supplied individual education, notably for girls, in Sauk Center, Minn., Sleighton Farms, Penn., Samarcand, N.C., Gainsville, Texas, and for boys, in New Jersey, California and elsewhere. In these training schools self-government and expert scientific guidance have met with success. Other social resources are clubs for boys and girls in industry, habit clinics, child guidance clinics, religious agencies, Big Brothers or Big Sisters, and Juvenile Protective agencies. These work most effectively under a co-ordinated philosophy of child care. To achieve this a conference is often held for social diagnosis.

Thus the old sentiments of revenge and deterrence give way to a concerted effort to understand, and to remove underlying causes. In this way sponsors of children's courts have become leaders in the scientific and humanitarian movement to prevent delinquency and to increase human happiness.

CHILDREN'S GAMES. The traditional games still played by children are nearly all very old. Many have been played in one form or another since the beginning of recorded history and perhaps longer. Some now confined to children, like Hide-and-Seek or Blindman's Buff, were commonly played by adults until at least as late as the 15th century. Others, like the simpler ball and skipping games, were originally not pastimes at all, but primitive rituals seriously performed to avert evil or to make the crops grow. They survive in juvenile play because the children imitated these rites, as they also imitated the domestic, hunting, farming and fighting lives of their elders. The resulting games were handed on to their successors who, with the innate conservatism of childhood, continued to play them long after the customs from which they sprang had vanished from the adult world. Thus modern games often contain fossilized relics of ancient belief.

Some games have flourished for centuries in particular countries and closely resemble others found elsewhere. Time has naturally modified some details, but the general plan usually remains the same so that the modern form, even with its variations, would probably be quite easily recognized by a child of classical or earlier times. Buck Buck, for instance, has scarcely changed since Petronius described it in his *Satyricon*. He tells us that boys in his day leaped upon the bent backs of others and beat them on the shoulders, crying *Bucca, bucca, quot sunt hic?* In like fashion, English lads today climb on a companion's back and cry "Buck, buck, how many horns do I hold up?" Greek and Roman boys trundled hoops in spring, and their sisters skipped with ropes of plaited vine strands. Virgil in his *Aeneid* speaks of whirling tops lashed round empty courts, and in Homer's *Odyssey* there is a description of Nausicaa playing ball with her maidens. All these pastimes are as popular now as they were in pre-Christian periods; and probably pursuit and combat games in the far past ran along much the same lines as Touch, Prisoner's Base, King of the Castle, Cowboys and Indians (lately translated into Gangsters and G-men or Spacemen and Martians) and We Are the Romans now.

Certain games tend to become fashionable at particular seasons. Tops normally come in during March, and are superseded about mid-April by skipping ropes. Hopscotch is also principally a March game, and so is kite flying, probably because March is a windy month. Marbles are popular in September and then give way to Conkers when the horse chestnuts are ripe. This does not mean, of course, that such games are never seen at any other time. But there are, nevertheless, definite seasons when they become a craze.

Traditional games may be roughly divided into two main categories: games of skill and chance and dramatic games in which a story or ritual is acted, with or without song accompaniment. Pursuit and combat games are essentially dramatic because they imitate hunting and war. The songs once attached to the more boisterous forms have mostly been lost, but frequently a counting-out or choosing rhyme is used. There are countless such rhymes.

Many skipping games, Thread-the-Needle, and Oats and Beans and Barley Grows derive from agricultural ritual dances. In the last named the players act the sowing of the seed; in the French game called *L'Avoine* they sow, reap, bind and thresh the crop. Courtship, wedding and funeral games are especially popular with girls, though boys often condescend to take part. One of the best-known funeral games is Jenny Jones, which should rightly be Jenny Jo, meaning sweetheart. This has a long and complicated song carrying the heroine through numerous domestic tasks to her death and then discarding one colour after another till black is finally chosen for her funeral. Sally Waters, Poor Mary Lies a-Weeping and In and Out the Window are singing marriage games. So also are Drop Handkerchief and Nuts in May, which represent marriage by capture, the bride being pursued in the first and dragged away in the other. The singular title of Nuts in May is really a corruption of knots (or posies) of May.

An extremely interesting type of dramatic game is that in which two players form an arch with uplifted arms and the rest hurry through until one is caught by the sudden lowering of the arch.

In some variants a choice is offered to the prisoner, who passes to left or right behind the leaders and takes part in a tug of war at the end. London Bridge is Falling Down is probably the best known of these games, and certainly the most interesting, for the words show clearly that it is based upon foundation sacrifice. In Scotland a similar game is called Broken Bridges; in America, Charleston Bridge; in France *Pont-Levis*. The Scandinavian version is *Brö Brö Brille*. Other English arch games are The Robbers are Coming to Town, How Many Miles to Babylon, and Oranges and Lemons, in which most of London's old City churches are mentioned by name.

Among the older games of skill are Fivestones (often called Dabs or Daubbins), which is played with pebbles, Knucklebones, Marbles, Guggles, played with coloured shells, Peg in the Ring, played with tops, Hopscotch and Merelles. The aim in each is to win something from another player. All were commonly played by men in country districts until well into the 19th century.

AMERICAN GAMES

Games played by children in the United States fall into two categories: traditional and improvised. The traditional games are those handed down from generation to generation, usually with fixed rules. Improvised games are invented on the spur of the moment by the players, with the rules made up as the game develops. Dramatic play falls between these two, because certain kinds of make-believe occur in generation after generation, with the broad outlines of the play remaining the same, but with the details varying from child to child.

In general, very young children play improvised games. At about four or five, traditional circle games with songs and pantomime are introduced. After that, a continuous acquisition of skills and game forms takes place, with the younger children learning from those slightly older.

Circle and Singing Games.—Among the first traditional games played are Ring Around the Rosy, Farmer in the Dell, Looby-Loo, Oats, Peas, Beans and London Bridge. At about six or seven years, the children begin to play games which involve chasing or tagging, like Drop the Handkerchief, Cat and Rat and Button, Button. Double circle games are often played at parties or on playgrounds under the direction of a leader. These include tag games such as Three Deep, partner-finding games similar to Odd Man Out and simple group dances like Grand Right and Left. Some ball games and stunt games are also played in the form of a circle. Among these are Jump the Rope, Passball, Touchball and Dodgeball.

Running, Chasing and Hiding Games.—Perennial favourites in this group are plain Tag, Hide-and-Seek and various types of foot races. Interest in these usually starts when the children enter elementary school and continues until they are about 12 or 13 years old.

Simplest forms of these games involve pitting one individual against a number of others. More complex forms, in which teams of players operate as a unit, also exist. In Crows and Cranes, for example, the players are divided into two groups, each of which chases the other at a prearranged signal until all the players on one side are caught. In other games one group hides while the other searches, and relay races offer victory to the speediest team. Team games appeal most to children past the age of eight.

Running games without chasing are also popular. In these the players compete to secure objects, places or partners or to avoid punishment.

Ball and Goal Games.—Baseball is undoubtedly the favourite ball game among boys in the U.S. Between the ages of 8 and 11 both boys and girls play some form of this game. After 11, girls tend to drop out of the play. Younger children and girls usually play a modified version of the game called Softball, in which the ball used is larger and softer than the official baseball. Other games derived from Baseball include Hand Baseball, Playground Kickball and Fungo Baseball, which eliminates pitching.

Football takes over during the fall season. A goal game played by two teams, it involves also some elements of combat. Although seven-year-olds try to play it, its demands are such that it can rarely be played correctly by boys younger than 14 or 15.

Other popular goal games are Basketball and Shinny, a derivative of Field Hockey. Shinny can be seen most often on city streets, played on roller skates, with pieces of broomstick and a tin can for a puck.

Games involving getting a ball over a net or hitting it against a wall are numerous. Among these, Handball, Tetherball, Wall Tennis and Table Tennis (Ping-pong) are played most frequently informally. In recreation and physical-education programs Dodgeball and Newcomb, which serves as an introduction to Volleyball, are favourites.

Special Games of Childhood.—Many of the games mentioned above are played by adults as well as by children; they may in fact be derived from adult games. A number of others, however, are uniquely characteristic of the culture of child groups. Among these are combat games like the Cowboys and Indians of small boys; these change later to Storming the Fort and Tug of War. Informal wrestling is a boy's "game" at seven and eight. Marbles and Darts are target games that start early, and Mumbletypeg is a contest of skill which the possession of a pocket knife seems to inspire. Leapfrog attracts both boys and girls until the end of elementary school.

Young girls have their own play rituals. One, Two, Three O'Leary, played with a rubber bounce ball, Jacks (using a small rubber ball and metal or plastic jackstraws), rope jumping to the tune of "Hot Peppers" or "Double Dutch" and Hopscotch must be in the repertoire of any six- to ten-year-old who wants to keep up with her age mates. Simon Says and May I? are popular games which require alertness, while Statues falls into the category of stunt games. Follow the Leader attracts boys as well as girls.

Games commonly played during quiet times may be divided into those needing special equipment and those needing little or none. The former group includes games of skill like Checkers and games of chance like Old Maid. Paper-and-pencil games, guessing games, spelling games, stunts and string games make up the second group. Twenty Questions, I Spy, Ghost, Charades, Ticktacktoe, Consequences, Cat's Cradle and Paper, Stone and Scissors are examples of these. Special party games include Pin the Tail on the Donkey, Post Office, Spin the Bottle and stunt races like the potato or three-legged race.

Gardner, *Handbook for Recreation Leaders* (1937); R. E. Hartley, "Children Grow Through Play," in S. M. Gruenberg (ed.), *The Encyclopedia of Child Care and Guidance* (New York, 1954). (R. E. H.)

CHILDRESS, a city in the "panhandle" of Texas, U.S., near the Red river and the Oklahoma border; the county seat of Childress county. It is on federal highways 287 and 83; is served by the Fort Worth and Denver City railway and has an airport about 5 mi. W. Pop. (1950) 7,619. Cattle, hogs, wheat, cotton and grain sorghum are raised in the vicinity. Gypsum and gypsites are found. The city has cotton compresses, gins, cottonseed oil mill, railway repair shops and packing plants; other products include bedding, soft drinks and dairy products. Settled in 1888, it was incorporated in 1892.

CHILDS, GEORGE WILLIAM (1829–1894), U.S. publisher, was born in Baltimore, Md., on May 12, 1829. In 1847 he established a bookshop in Philadelphia, and two years later organized the publishing house of Childs and Peterson. In 1864, with Anthony J. Drexel, he purchased the *Public Ledger*. He died at Philadelphia, Feb. 3, 1894. Childs was known for his public spirit and philanthropy. He erected memorial windows to William Cowper and George Herbert in Westminster abbey (1877) and to Milton in St. Margaret's, Westminster (1888), a monument to Leigh Hunt at Kensal Green, to Shakespeare a memorial fountain at Stratford-on-Avon (1887) and monuments to Edgar Allan Poe and to Richard A. Proctor. He gave Woodland cemetery to the Typographical Society of Philadelphia for a printers' burial ground, and with Anthony J. Drexel founded in 1892 a home for union printers at Colorado Springs, Colo.

His *Recollections* were published in Philadelphia in 1890.

CHILD WELFARE AND CHILD LABOUR. The heavy toll inflicted on children by the wars of the 20th century impelled such recognition and measurement of their needs as modern skills would permit. Expansion and improvement of services to children was marked during the second quarter of the century, calling for financial support in large measure from governments and individuals and the recruitment and training of professional workers in all parts of the world.

Origins of Child Welfare.—Child welfare had some recognition in ancient legal codes and much religious sanction in the teachings of Buddhism, Christianity and Judaism. Hospices for the care of travellers, the sick and the poor authorized by the early Christian church at the council of Nicaea in A.D. 325 were among the first known facilities for the protection of children as well as adults. Concepts of communal responsibility for child welfare acquired gradually extended horizons, both in oriental and western countries.

The development of social security and social services under governmental auspices focused attention on the age-old needs of children. In several countries there was an organization of services to children following wars, epidemics or famines severe enough to create large numbers of orphans. Wars, even civil wars as in Switzerland at the end of the 18th century and in the United States after the middle of the 19th century, left orphans and half-orphans to an extent that warranted the establishment of institutions for dependent and neglected children. World Wars I and II were followed by the organization of relief, health services and facilities for child welfare on a scale without precedent in history but still small in proportion to the destruction of homes and the impoverishment of family life which these conflicts produced.

Far more significant than the emergency wartime and postwar efforts to relieve misery was the development of international planning in behalf of the children of the world. A better world for children was envisaged in the Universal Declaration of Human Rights, approved Dec. 10, 1948, by the general assembly of the United Nations. Their interests were especially stressed in: "The family is the natural and fundamental group unit of society and is entitled to protection by society and the State" (article 16, section 3), and "Motherhood and childhood are entitled to special care and assistance. All children, whether born in or out of wedlock, shall enjoy the same social protection" (article 25, section 2). Steps toward enactment of a Declaration of the Rights of the Child were taken within the United Nations in 1950. A draft declaration was prepared for consideration in turn by the Economic and Social council, the Commission on Human Rights and the general assembly.

There had been little international exchange of information about child welfare before the early years of the 20th century, when the development of education, health and social services led to the organization of professional societies in many countries.

International Conferences.—International conferences of professional workers serving children had been held under various auspices, however, some devoted entirely to child welfare and some covering several fields of work but dealing largely with child welfare. Ten congresses with delegates from Europe and America, including the United States, were held in London, Eng., and six European cities, the first and last being in Paris, Fr., in 1883 and 1933, respectively. Two congresses, limited to the Balkan countries, were held in 1936 and 1938, respectively. The International Conference of Social Work held the following seven sessions: Paris, 1928; Frankfurt-on-Main, Ger., 1932; London, 1936; Atlantic City, N.J., with concluding meetings at New York city in 1948; Paris, 1950; Madras, India, 1952; and Toronto, Ont., 1954. The last six of these conferences brought together the same professions and organizations which previously had organized the international child welfare congresses.

The Pan American Child congress held the following sessions: Buenos Aires, Arg., 1916; Montevideo, Urug., 1919; Rio de Janeiro, Braz., 1922; Santiago, Chile, 1924; Havana, Cuba, 1927; Lima, Peru, 1930; Mexico City, Mex., 1935; Washington, D.C., 1942; Caracas, Venez., 1948; and Panamá, 1955. Resolutions passed by the congress led to organization of the International American Institute for the Protection of Childhood in Montevideo in 1927. The World Federation for Mental Health founded in 1948 was an outgrowth of the first International Congress on Mental Health. The Latin American Conference on Nutrition was under the auspices of the Food and Agriculture organization.

The League of Nations.—Article 23 of the covenant of the League of Nations requested member states to endeavour to secure and maintain fair and humane conditions of labour for adult and child workers, to take measures for the prevention and control of disease and to entrust the League with general supervision over the execution of agreements on the traffic in women and children.

The agencies given responsibility for services authorized by the League were the International Labour organization, which continued after dissolution of the League as one of the international bodies safeguarding the rights of children; the Health organization, which was succeeded by the World Health organization; and the Advisory Committee on Social Questions and the Social Questions section of the League secretariat.

In 1921 the League appointed an Advisory Committee on Traffic in Women and Children, replaced in 1925 by the Advisory Commission for the Protection and Welfare of Children and Young People, with two subcommittees, the Traffic in Women and Children committee and the Child Welfare committee.

Among the subjects studied by the Child Welfare committee between its appointment in 1925 and its reorganization in 1936 were the age of marriage and consent; legal status of illegitimate children; juvenile courts and their related services; motion pictures and child welfare; and measures taken in various countries for the protection of children and young persons from the consequences of economic depression.

United Nations Agencies.—The United Nations created or encouraged the organization of services entirely or partly concerned with the welfare of children, and co-ordinated the work of these and other international agencies serving children, some of which were in existence before the UN was organized in 1945. Co-ordination of the work of the various specialized agencies and the UN became a principal responsibility of the Economic and Social council and the Administrative Committee on Co-ordination consisting of the secretary-general of the UN and the executive officers of the specialized agencies. The unprecedented organization and expansion of relief and child welfare services during the decade prior to mid-century made their co-ordination a tremendous and urgent task.

The United Nations International Children's Emergency fund, after 1953 called the United Nations Children's fund (UNICEF), was established in Dec. 1946 by the general assembly of the UN for the relief and rehabilitation of children in war-torn countries and for child health throughout the world. Though not a direct descendent, UNICEF inherited much of the responsibility for feeding children and providing other child welfare services which had been a part of the load carried by the United Nations Relief and Rehabilitation administration. Though UNICEF received much less financial support than UNRRA, it was less restricted in the number of countries it could enter and less subject to military and political controls. UNICEF was supported by voluntary

contributions from governments and individuals; by 1955 nearly $200,000,000 had been provided from 48 countries, about 70% of which was from the United States. The work of the UNICEF was not restricted by national boundaries as were many international services. It maintained programs on both sides in war-torn China and operated freely in the four zones in Germany and Austria and in the countries of central and eastern Europe. Prior to 1950 the fund provided a daily supplementary meal for 4,000,000 to 6,000,000 children and nursing and pregnant women. The program in the east, including the East Indies, consisted mostly of supplying medicines and equipment and training local personnel in techniques for the control of specific child welfare problems. In Europe and North Africa much progress was made in the world-wide campaign to test 100,000,000 children for tuberculosis. A resolution adopted by the general assembly of the UN, Dec. 1, 1950, revised the policy of the UNICEF. Relief programs were replaced by emergency and long-range projects whereby supplies, training and advice were provided in underdeveloped countries with a view, wherever appropriate, to strengthening the permanent child health and child welfare programs of the countries assisted. By 1954 most of these countries had realized the advantages of UNICEF services and instead of matching UNICEF funds, as in previous years, they provided several times as much as the UN appropriations for advancing the welfare of their own children. Thus facilities for manufacturing powdered milk had been developed in the near east, Asia and Latin America where formerly milk and other relief supplies had been imported.

The World Health organization (WHO), created July 22, 1946, from its beginning gave priority to children in much of its work. In addition to the joint programs in which it promoted the mass feeding of children, improved nutrition and instituted more effective methods of food production, the representatives of WHO surveyed the tuberculosis problem in many countries and set up laboratories for the manufacture of Bacillus-Calmette Guérin (BCG) vaccine. Outstanding among its achievements was its campaign against malaria. WHO also issued daily radio warnings of epidemics of smallpox, cholera and other pestilential diseases. Venereal diseases, in some areas affecting nearly half the population, were combated; prenatal and infantile syphilis were treated with penicillin in mass campaigns in several countries. The sanitation program of the WHO led to improvement of water supply and sewage disposal systems and destruction of disease-carrying insects. With such improvements the death rate among infants in some areas was cut from 30 to 3 per 100 births in a comparatively short time. The WHO and the Food and Agriculture organization (FAO) jointly promoted a "food for health" program, stressing health education of the public.

The United Nations Department of Social Affairs made a comparative survey of juvenile delinquency in five regions: (1) Asia and the far east; (2) Europe; (3) Latin America; (4) the middle east; and (5) North America. Reports of findings, published in 1952 and 1953, were widely circulated and studied in preparation for a world conference on the prevention of crime and the treatment of offenders planned for 1955.

The International Refugee organization (IRO) was established as a nonpermanent specialized agency under a constitution approved by the general assembly of the UN on Aug. 20, 1948, and discontinued in 1952. Children, often without trace of their parents, constituted a large portion of the 1,600,000 refugees and displaced persons remaining in need of protection and sustenance in Europe and the middle and far east at that time. Prior to 1948, approximately 7,000,000 persons had been repatriated with the help of the military and UNRRA.

The United Nations Korean Reconstruction agency (UNKRA) was the channel through which much relief and child care were provided war orphans and other children in South Korea. By 1954 the total spent by all relief agencies, including UNKRA, exceeded $500,000,000. Nearly one-third of the 150,000 severely deprived war orphans or other homeless children were given care in about 350 orphanages. The foreign military forces, mostly from the United States, made large contributions to these efforts, as did religious bodies and nonsectarian relief agencies such as the American-Korean foundation. UNKRA and UNICEF, by 1954, were operating about 100 feeding stations from which powdered milk was made available to more than 1,000,000 persons, mostly children. UNKRA also assisted the government of South Korea in reorganizing and expanding its public schools.

Private Agencies.—Children were also well served during and after the World War II years by sectarian relief agencies under Jewish, Protestant or Roman Catholic auspices, such aid coming from the more favoured parts of Europe and overseas. Many were privately aided through the Cooperative for American Remittances to Everywhere (CARE). Steps to co-ordinate the financial and service activities of private relief agencies had been taken with the organization in 1943 of the American Council of Voluntary Agencies for Foreign Service, with membership including 52 agencies.

The United States Committee for the Care of European Children, in existence from 1940 to 1953, brought thousands of children to temporary or permanent homes in the United States. During World War II most of these were British children, many of whom returned to their homes in the United Kingdom. After the war nearly all children brought to the United States were from camps for displaced persons in western Europe. The preparation of these children for immigration under quota regulations, their transportation under escort and their reception was one of the greatest child welfare achievements during and after the war. The Committee safeguarded these children before and after placement, including the many who were legally adopted, by utilizing the country's network of competent governmental, sectarian and nonsectarian child care agencies. Except for temporary reception service in institutions most of the care thus provided was in foster homes or the homes of relatives or friends.

DEVELOPMENTS IN VARIOUS COUNTRIES

The nations of the British commonwealth during the period 1930–50 developed health and social services for children and social insurance which did much to offset the demoralizing influences of World Wars I and II. Family allowances, first provided in Australia and New Zealand, were introduced in the United Kingdom under the Beveridge plan and in Canada under the Marsh plan for social security. These allowances, recognizing the size of each family, permitted better balanced diets. The Children bill enacted by the British parliament in June 1948 transferred from local authorities to the home office responsibility for services to children up to the age of 18 who were deprived of normal home life. This national authority, with jurisdiction over juvenile courts and legislation for the protection of children, was authorized to decide whether a child was to receive foster care in an institution or a foster home, without restrictions previously imposed by the Poor law and its means test for determining public responsibility.

Sweden and Switzerland sustained their previously superior services in the fields of education, health and welfare and carried to adjoining war-torn countries material aid and cultural leadership. Among those countries seriously damaged by World War II which took steps to improve their services to children was Finland, which extended its well-baby clinics and anticipated in its public health law the development of such clinics in every community. France also extended its school health services and maintained its social security benefits for maternity leave and related services. Poland sharply reduced its infant mortality rate, stressing the needs of farm communities and mothers and children, and increasing the facilities for training physicians. The U.S.S.R. extended various services for children after the war.

India held a child welfare exhibition in New Delhi in 1949, one of several activities following the second annual session of the All India Conference of Social Work held in Dec. 1948.

Brazil's progress in the development of maternal and child health services was reflected in the findings of the second Brazilian Conference on Child Care and Pediatrics held in 1948. Uruguay developed a unified health and welfare service, the Council of the Child, an outgrowth of a children's code enacted in 1934. Aid to mothers unable to provide adequate support for their children

was authorized. Care of dependent children in foster homes was also extended under the Uruguayan program.

United States.—The child population of the United States had an unprecedented increase in the decade prior to mid-century. The 1947 record total of approximately 3,720,000 births was in sharp contrast with the 2,360,000 (approximate) born in 1940. During the three years following 1947 the number of births occurring annually remained at about 3,500,000, but rose steadily thereafter until in 1954 it exceeded 4,000,000. The country was embarrassed by the limited facilities and services for children available in the fields of education, health and social service and the lack of suitable housing for the large number of new families during and after World War II.

A three-year nation-wide study of child health services, completed in 1949 by the American Academy of Pediatrics with the assistance of other agencies, notably the children's bureau and the public health service of what was then the Federal Security agency, gave a comprehensive appraisal of health services. Two over-all needs emphasized were the inadequacy of the general practitioner's training in pediatrics and the scarcity of health services and hospital facilities for children in rural areas.

About 4,000,000 children, 5 to 17 years old, were not enrolled in any school at mid-century. The shortage of teachers and school buildings had become acute and efforts to secure enactment of legislation for federal aid to public schools had been unsuccessful.

Social services to children, first developed under sectarian and other private auspices, were greatly extended after passage of the Social Security act in 1935. Aid to dependent children, which soon became effective in all states, was available at mid-century to about 1,500,000 children and 585,000 families. In June 1954 aid was provided for 1,565,000 children and 581,000 families. Children in rural communities and in areas of special need were provided with various social services under the child welfare services provision of this act. The children's bureau of the department of health, education and welfare continued to provide federal supervision of child welfare services, just as the bureau of public assistance supervised aid to dependent children and aid to the blind, all administered by state and county authorities.

Maternal and child services for crippled children had become major items in the budget and program of the children's bureau. One of the most widely circulated of all federal publications was *Infant Care*, a pamphlet which had reached millions of American mothers.

The National Commission on Children and Youth, created during World War II by the children's bureau, played an important role in planning for the mid-century White House Conference on Children and Youth. It also helped co-ordinate the child welfare work of federal and national agencies in education, health, recreation and social service, giving attention to problems such as the day care of children of working mothers.

The mid-century White House Conference on Children and Youth was held in Washington in Dec. 1950. More than 5,000 workers and other interested citizens and youth themselves were invited by Pres. Harry S. Truman to constitute this, the largest of the five successive White House conferences on child welfare, held at ten-year intervals beginning in 1909. The fields of service represented included education, health, recreation, religion and welfare. The conference focused attention on existing services to children, developments during the previous decade and unmet needs as determined by preconference studies.

The development of child guidance clinics, well advanced by 1940, was slowed down by the scarcity of psychiatrists and psychologists in wartime. The appropriation of public funds, including federal provisions for research and training of psychiatrists, a repercussion from the military reliance upon such services, included child guidance and the treatment of mentally disturbed children in the programs thus supported.

After World War II facilities for the study and treatment of emotionally disturbed children were developed under various auspices. The Child Welfare League of America, under a grant from the Marshall Field foundation, in 1952 published the report of a two-year study of resident treatment centres for emotionally disturbed children operated under private auspices. The states which established similar institutions included Connecticut, Kansas, Massachusetts, New Hampshire, New Jersey, New York and Ohio. The U.S. public health service facilities at Bethesda, Md., include seven research institutes, one of which, established in 1953, is a clinical centre where a small group of emotionally disturbed children receive study and treatment.

Child development, which had become the object of research by pediatricians, psychologists, nutritionists, educators and social workers, had absorbed the attention of many leaders and organizations. In addition to research, these programs included training of workers in several professions and extensive efforts in parent education. Outstanding among the centres engaged in this work at mid-century were the Rochester Child Health project (Rochester, Minn.), The University of Chicago, Columbia and Yale universities and the state universities of California, Iowa, Minnesota and Ohio.

CHILD LABOUR

The movement for the legal regulation of child labour began at the close of the 18th century when, with the rapid development of large-scale manufacturing in Great Britain, the exploitation of very young children in industrial work attracted public notice. The first child labour law, adopted in England in 1802 in an attempt to control the evils of apprenticing pauper children to cotton-mill owners, was ineffective for lack of provisions for enforcement. The Factory act of 1833 was the first law with a system of factory inspection.

The first International Labour conference, in Berlin, Ger., in 1890, did not reach agreement on standards and was followed by similar conferences and other international efforts. The International Association for Labour Legislation, established at Basle, Switz., in 1900, a private organization with branches in at least 16 countries, promoted child labour provisions as part of other international labour legislation. Such organizations successfully urged inclusion in the treaty of Versailles of 1919 provision for the International Labour organization (ILO), affiliated with the League of Nations and including all members of the League.

The International Labour office, a part of the ILO, drafted conventions which were submitted to member countries through the International Labour conference for ratification, with ratification including an obligation to enact a law carrying out provisions of the convention.

The 1944 International Labour conference adopted a declaration redefining the aims and purposes of the ILO. Further action in 1945 and 1946 provided that any member of the UN might become a member of the ILO by declaring its formal acceptance of the obligations of membership. Other countries could be enrolled as members upon vote of the conference.

Reverses in the enactment and enforcement of child labour legislation came during and after World War II. In the struggle for survival of individuals, families and nations, children throughout the world were required to do the work of adults, some even as soldiers. In the most devastated countries, young children sank to levels unprecedented in the 20th century, engaging in hazardous work and some even in such occupations as smuggling and prostitution. Consequently, postwar international and national efforts to reduce and control child labour included a comprehensive and searching review of the basic rights of children and families and pointed to correlations between low family incomes and the exploitation of children. Among the several international conventions adopted after the war was a revision in 1948 of the 1919 convention concerning the night work of youth employed in industry. Regional international conferences of the ILO gave special attention to conditions of work of children engaged in agriculture, other than on the home farm; child labour in the coal and inland transport industries; and elemental protective measures in the middle east, Asia and Latin America.

The ILO submitted a report on child labour in relation to compulsory education for consideration at the 14th International Conference on Public Education held in Geneva, Switz., in 1951. This provided a basis for international study of the minimum age of

admission to work and the age of compulsory school attendance. Measures for the protection of young workers in Asian countries, on the agenda of the Asian regional conference of the ILO held in Tokyo in 1953, recognized the growing desire for education among the peoples of Asia and outlined legislation and steps for realization of objectives in the control of child labour and the provision of both elementary and vocational education. A member of the staff of the ILO made a study of juvenile employment in Latin America, published in the *International Labour Review* in March 1954.

Child Labour in the U.S.—Approximately 2,000,000 U.S. children between the ages of 14 and 17 were employed part time or full time at mid-century, according to estimates of the U.S. census bureau. Nearly half of these worked 35 hours or more weekly.

Early efforts to control child labour, prior to 1850, sought to prohibit employment of children under the age of ten in factories—a problem then also being combated in England. This was in contrast with federal regulations which in 1950 specified for certain employment a minimum age of 16. But in agriculture, especially as migrant labourers, children nine years of age and even younger still were employed in the United States at mid-20th century. Wartime employment of children reached a peak in 1945 of almost 3,500,000 workers 14 to 17, with summer employment bringing the total to about 5,000,000.

Most child labour legislation continued to be a state responsibility. Only 19 states in 1949 prohibited employment of children under 16 during school hours, and some of these states exempted children in agriculture and other industries. All states required school attendance up to 16 years of age or higher, though many were exempted and in some states the laws were poorly enforced.

Federal legislation, though limited, had effected certain nation-wide controls. Two federal child labour laws, declared unconstitutional in 1918 and 1922, were followed by the Fair Labor Standards act of 1938. This act, applying only to the production of goods for interstate or foreign commerce, established a minimum age of 16 and, in occupations particularly hazardous, 18. An amendment effective Jan. 25, 1950, prohibited employment of children under 16 years of age in agriculture during school hours, but did not apply to children working for their parents or those in intrastate agriculture. (*See* also CHILDREN: PROTECTIVE LAWS.)

(H. W. HE.)

CHILE, a republic on the Pacific coast of South America, occupies the western slope of the continent south of Peru. It is a narrow ribbonlike country, averaging only 110 mi. in width, but extending about 2,650 mi. in length, from 17° 30′ S. to 55° 59′ S. In the northern hemisphere this distance would be equivalent to the stretch from southern Mexico to southern Alaska. Although Chile has a greater inhabited latitudinal range than any other country in the world, about 90% of the people live in middle Chile, from 30° S. to 42° S. The total area of the country is 286,323 sq.mi., slightly less than the combined areas of England, Scotland and France, but middle Chile is hardly bigger than England and Scotland alone, and one-third of it is exceedingly rugged. In addition to its main area Chile owns the Juan Fernández Islands, Easter Island, and a number of other islands in the South Pacific ocean, and lays claim to a sector of Antarctica from 53° W. to 90° W. In northern and middle Chile the country is composed of three parallel strips: the Andes on the east, the coast range on the west and a series of lowlands between. South of 42° S. there is no central lowland, a discontinuous island chain standing guard before a fjorded mountainous coast. Northern Chile is a desert, notable for the production of copper and nitrates; southern Chile is a cold, wet region of little attractiveness and limited economic potential; but middle Chile is climatically most agreeable, and is the centre of agriculture, livestock ranching and industry.

Physical Features.—The northern coast of Chile conveys the impression of a great land barrier with a remarkably even sky line. This barrier consists of a coastal range with gently rounded upper surfaces that descend only slightly to the floors of the interior basins, or pampas, whereas the seaward face is generally a steep escarpment that drops from an elevation of 2,000 or 3,000 ft. directly into the sea. This coastal bluff is a serious obstacle to transportation and settlement. Only in isolated spots is there a sufficiently wide bench or alluvial fan for a town site. South of Valparaíso the coastal escarpment is more broken and the elevations assume the characteristics of a mountain chain. From Chiloé south, subsidence has taken place, and only the higher parts of the coastal range reach above sea level as a series of islands.

The great barrier ranges of the Andes, which make up fully a third of the country, may be divided about 27° S. into a shorter northern and a longer southern section. The southern part is composed of a single rather narrow range, whereas the northern is made up of two or more roughly parallel ranges enclosing a series of plateau surfaces whose major development, because of the narrow shape of Chile, is to be found in Bolivia and Argentina. The Andes increase progressively in height from an elevation of 6,000 or 7,000 ft. at the southern end until they culminate at 32° 39′ S. in Aconcagua, which, with an elevation of 22,835 ft., is the highest peak in the western hemisphere. The peak, however, is located just across the border in Argentina. Uspallata pass, el. 12,650 ft., lies immediately south of Aconcagua, and is the most important international pass in South America. Below it at 10,469 ft. is the tunnel of the transcontinental railway that connects Valparaíso with Buenos Aires. Farther south the lower average elevation of the mountain ranges results also in lower passes. In the lake district south of 39° S. most of the passes are under 5,000 ft., a circumstance that greatly facilitates trans-Andean communication in that area. The Strait of Magellan in the extreme south is a sea level pass through the Andes. The southern Andes are intensively glaciated—U-shaped valleys and glacially-sculptured peaks being the rule. Large glaciers are still to be found in many places, and extensive moraines are in evidence, many of them acting as dams for lakes. A series of young volcanic cones are superimposed on the Andes between 34° and 43° S., some of them of striking beauty and symmetry.

North of 30° the Andes are divided into several chains of which the western forms the major eastern boundary of northern Chile. Two railroads lead across it into Bolivia, the one from Arica at 13,956 ft. and the other from Antofagasta at 12,972 ft. In 1948 the Transandine railroad of the north was opened through Socompa pass (el. 12,657 ft.), connecting Antofagasta with Salta, Argentina. The extreme ruggedness, the aridity and the cold of this section limit crop raising and grazing, but it is highly mineralized, although handicapped by lack of water. One of the largest copper deposits known is located at Chuquicamata (22° 19′ S. lat.) at an elevation of 9,300 ft. It has been worked since 1915 by U.S. interests. This enterprise is by far the most important economic activity in northern Chile.

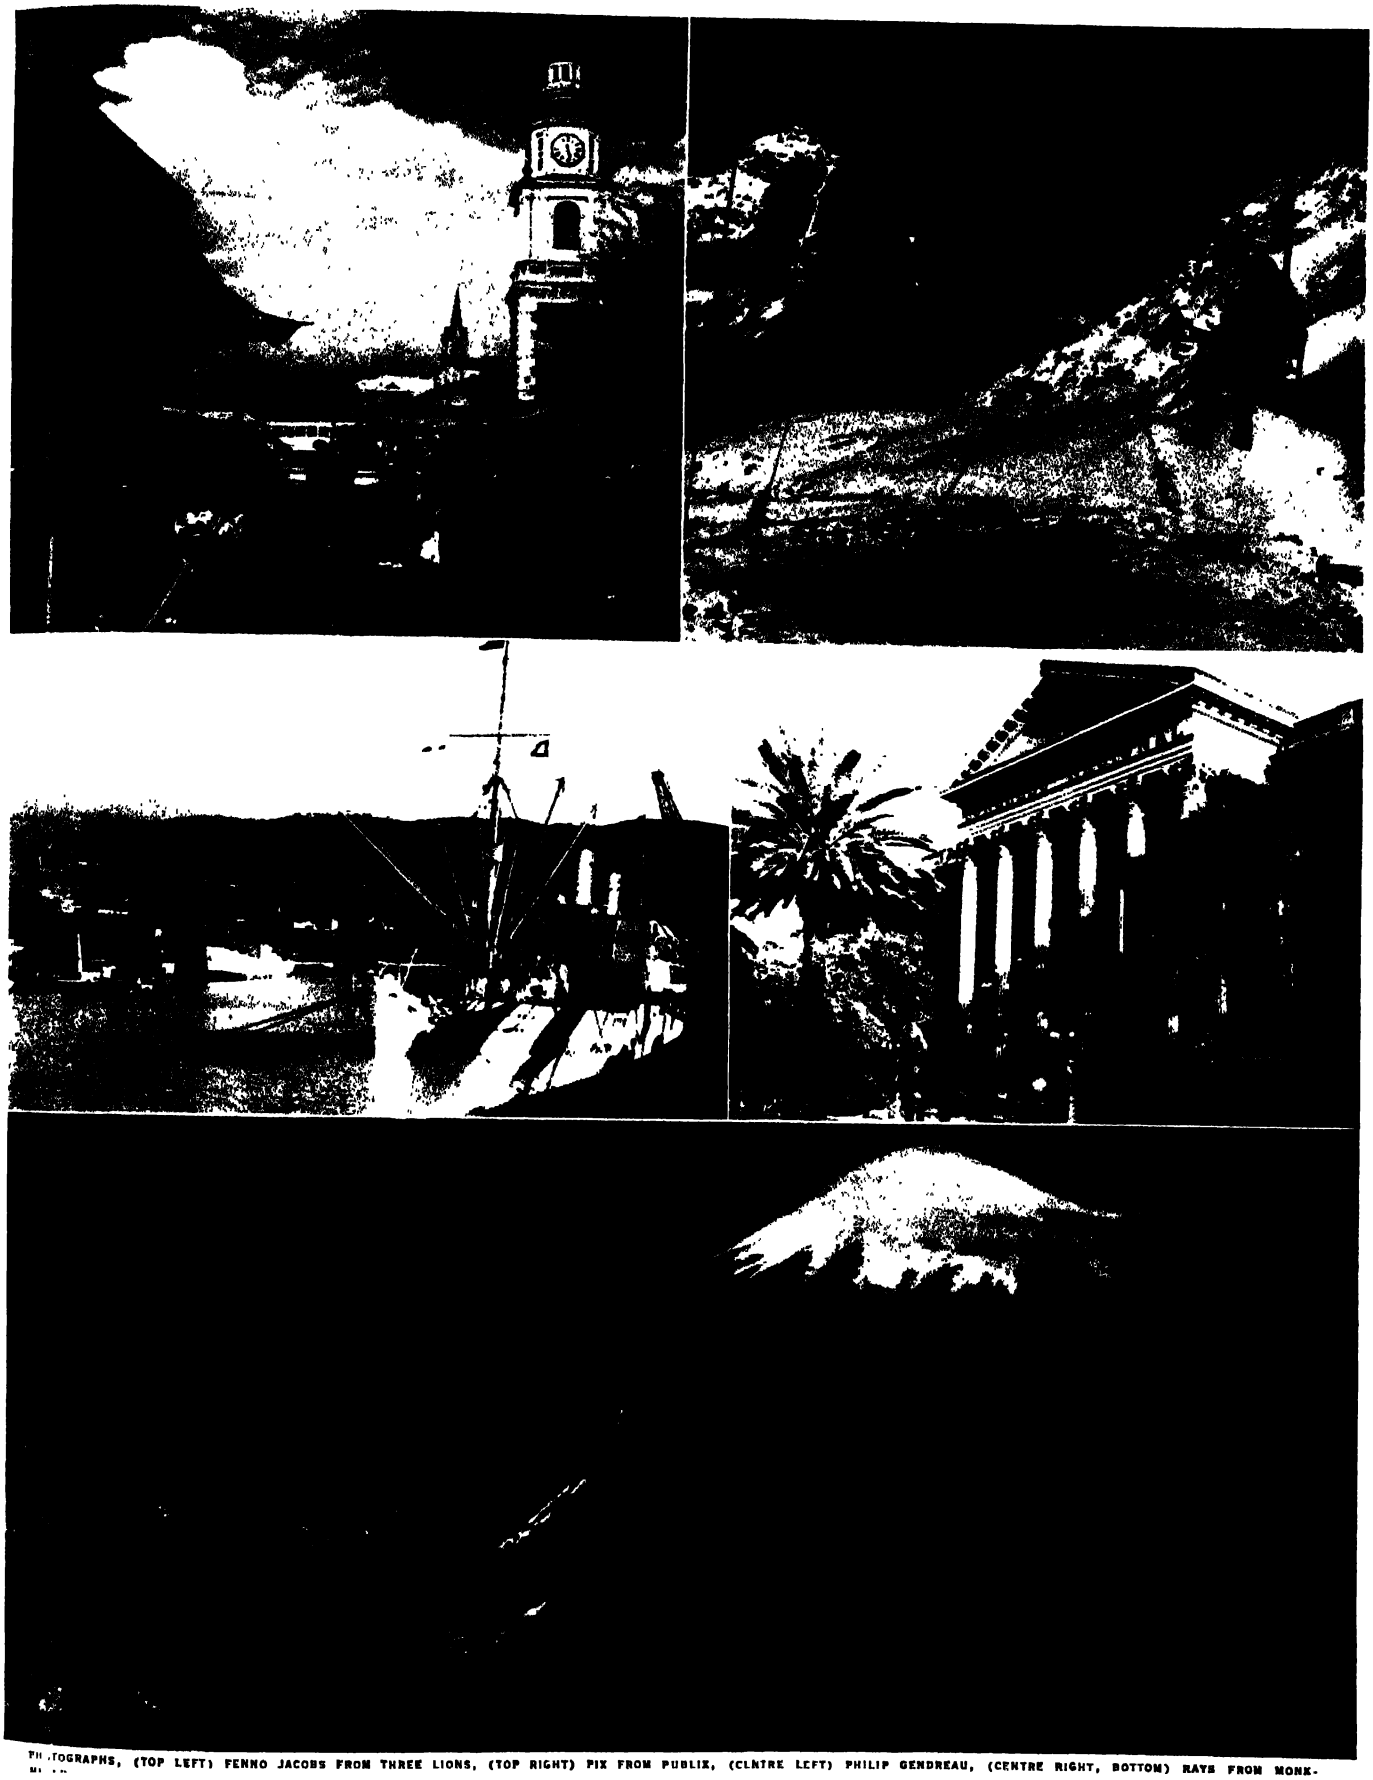
Between the coast range and the Andes lies the so-called longitudinal valley. This is not a true valley but an irregular depression, in places 25 to 50 mi. wide and at times reaching an altitude of 3,000 to 4,000 ft. In some sections it is broken by isolated groups of mountains or by spurs from the main range, which divide the portion above 30° S. into a series of basins, locally known as pampas. The most northern of these is the Tamarugal extending north from the river Loa. This differs from the others in that the ground water in places lies within four or five feet of the surface. Although on the whole this pampa is very barren of vegetation there are remnants of what once must have been extensive thornwood areas. The desert of Tarapacá lies in the western part of the Tamarugal pampa and furnishes a portion of Chile's nitrate. About 60% of total production in 1952 came from the neighbouring province of Antofagasta, and a very small amount came from Atacama still farther south. In this province the desert pampas end with an irregular mass of low mountains

which occupy the whole belt between the ranges, until approximately the latitude of Valparaíso. There begins the central valley, one of the finest agricultural valleys in the world, which is continued south until approximately 40°. The longitudinal valley then gives way to a series of lakes, and then to a complex series of beautiful islands which are but sparsely inhabited.

Geology.—Along the coast of Chile lies a belt of rocks formed mainly of old granite and schist and overlying Cretaceous and Tertiary deposits; farther inland is the western cordillera of the Andes, which is composed chiefly of intrusive masses, volcanic rocks and folded Mesozoic beds. The deposit in the great longitudinal valley of Chile, which lies between these two zones, is formed of débris that is in places more than 300 ft. thick. In northern Chile the rocks of the coastal zone, which disappear northward beneath the Pacific, consist mainly of isolated masses that stand close to the shore or that project into the sea. South of Antofagasta these old rocks, which there begin to rise to higher levels, form a nearly continuous belt along the coast, extending southward to Cape Horn and occupying the greater part of the islands of southern Chile. They are greatly folded and are doubtless Palaeozoic. In northern Chile the Cretaceous and Tertiary beds of the coastal zone are of small extent, but in southern Chile the Mesozoic beds, which are at least in part Cretaceous, form a rather wide band. The Tertiary coastal beds include both marine and terrestrial deposits, and most of them appear to be of Miocene or Pliocene age. The whole of the northern part of Tierra del Fuego consists of plateaus formed of horizontal Tertiary beds. The northern part of the Chilean Andes, which is the western cordillera of Bolivia, consists almost entirely of Jurassic and Cretaceous sediments and Tertiary eruptive rocks. The Mesozoic beds are thrown into a series of parallel folds, which run in the direction of the mountain chain. Into these folded beds are intruded granitic and other igneous rocks of Tertiary age, and upon this foundation rise the cones of Tertiary and later volcanoes. Triassic rocks are found only at La Ternana, near Copiapó, where coal seams containing upper Triassic (Rhaetic) plants have been found, but the entire Mesozoic series appear to be represented at different places. The Mesozoic rocks are chiefly marine sandstone and limestone, but they include also tuff and conglomerate of porphyry and porphyrite. These porphyritic rocks, which form a characteristic element of the Southern Andes, are volcanic, and as they contain marine fossils they must have been laid down beneath the sea. They are not confined to any one geologic horizon but occur at different levels in the Jurassic beds and at some places in the Cretaceous. Here and there they may be traced laterally into the more normal marine deposits of the same age. A large part of the Andes is covered by the products of the great volcanoes that still form the highest summits. The volcanic rocks are liparite, dacite, hornblende andesite and pyroxene andesite. The recent lavas of the volcanoes in southern Chile are olivine-bearing hypersthene andesite and basalt.

(W. H. Hs.; G. McL. Wo.; H. J. Bn.)

Ports.—As outlets for its products Chile is unusually rich in ports, but singularly unfortunate in harbours. Nearly all of these are mere open roadsteads, requiring the transfer of goods by lighters. Moreover the heavy swells along the major part of the coast frequently cause the transfer of goods to be abandoned temporarily for hours, or even days. Of the 57 ports listed relatively few are very important in international trade, and because of the abrupt slope of the ocean bottom artificial protection is both costly and difficult. Many breakwaters have been constructed of recent years, however, particularly at Antofagasta and Valparaíso, but without securing thoroughly safe anchorage at these ports. Valparaíso, with its modern wharves and other harbour facilities, also illustrates the case of an older port which is favoured by the government in its fight for continued supremacy. In colonial times it was selected as the outlet for central Chile because the traffic of that day could pass from the capital to the coast without encountering any considerable ford. Better natural harbours are to be found in the vicinity, both to the north and south of it, and Valparaíso today is meeting serious competition from San Antonio, 50 mi. below, which ships the large copper output from the Rancagua district and is gaining in general commerce. Valparaíso is also handicapped by the unwise selection of the route for the railroad leading to the interior, although a modern highway joining it to Santiago has overcome the difficulties to some extent. Antofagasta is the leading nitrate port and shares with Tocopilla the exports and imports passing to and from the copper centre at Chuquicamata. Arica, the northernmost port, gains its economic importance as an outlet of the Bolivian plateau but formerly played a more conspicuous part as a diplomatic pawn. This port and its fellows in the north, like Valparaíso, are hampered by railway conditions. Talcahuano in the south is the chief naval station of the country as well as the commercial outlet of an extensive section. Near by, Coronel is one of the three ports serving the coal producing district as Cruz Grande, north of Valparaíso with its direct docking facilities, serves the iron mines of El Tofo. Valdivia, through its port, Corral, and Constitución are able to make some commercial use of the rivers on which they are located. Punta Arenas on the Strait of Magellan gives Chile the distinction of having the most southerly port in the world.



(W. H. Hs.; I. J. C.; H. J. Bn.)

Rivers.—Because of the general outline and topography of the country, the rivers are short and unimportant except for the life giving waters they may bring, and have little or no significance in directing the settlement or trade of the country. In the north they are few, and for a distance of approximately 600 mi., the waters of only one, the Loa, reach the sea throughout the year. This stream, the longest in Chile (273 mi.), has made possible certain settlements. The Copiapó, 186 mi. long, marking approximately the southern limit of the northern desert, once discharged its waters into the sea, but rarely does so now, as the needs for irrigation are greater than the supply. The rivers to the south are better fed at their heads and flow through much less arid regions. Some of them become raging torrents at certain times of the year, and a number have been harnessed for the production of electricity. The electrification of the road in the Chilean section of the transcontinental is complete, together with the main line to the capital and other minor developments. With the increased demand for electric current has come also the storage of waters for irrigation.

Lakes.—The lakes of Chile have little significance in the life of the people. In the north occur occasional salt playas, which are dry the greater part of the year. In central Chile, south of the Bío-Bió river, there is a series of very picturesque lakes in the provinces of Cautin and Llanquihue. The largest of these lakes are Ranco and Llanquihue, the former with an estimated area of 200 sq.mi., the latter 300 sq.mi. Because of its natural beauty, the lake region has become a resort place for Chileans and tourists at all seasons of the year.

Climate.—Not many countries have the climatic extremes of Chile. The north is an absolute desert, but there is a gradual increase in precipitation through central Chile until it reaches a total in south Chile not surpassed by any extra-tropical region. The strong permanent high pressure area formed over the Pacific at about 30° dominates the climatic conditions of northern Chile, accounting for its northward flowing winds and consequently for the great aridity of the region. South of this high pressure area is a region of variable winds that accompany the passage of cyclones moving from west to east across the South Pacific ocean. The cyclonic belt moves north in the winter and south in summer, at times causing violent winds to sweep the Andean passes between Chile and Argentina. In central Chile it makes its influence felt as far north as the region of Coquimbo, where it produces winter rains. At Santiago, this migration is shown in a winter rainfall (3.4 in. in July, 0 in. in January, annual 14.4 in.). In certain years or series of years this migration does not take place or goes on beyond the normal and the result is either great droughts or heavy rains.

South of the southern tip of Chile is a belt made up of numerous low pressure areas, with unusually high barometric gradients, which produce very strong winds averaging over 30 mi. per hour, and reaching velocities three or even four times as high. These moving low pressure areas give a constant succession of storms

for which the passage around the Horn has been renowned ever since its discovery, and farther northward give the lower part of Chile its westerly winds and immense rainfall.

North Chile is quite the driest region of which there is any record. During a 21-year period Iquique had an average rainfall of 1.5 mm. (0.06 in.) and Arica for a 19-year period had less than one-half as much. These averages do not represent normal conditions but show that north Chile is not entirely rainless. On the Andean slopes of this region, periodic summer rains fall as low as 8,000 ft. with occasional heavy snows. These may produce stream floods, which spread mud and gravel over the valley and give rise to temporary salt lakes. Needless to say such rains are calamitous; nitrates are destroyed, the work of the *salitreras* paralyzed, and the homes of the people, because of the poor mud roofs, practically ruined. This absolute desert condition does not change until in the latitude (27°) of Caldera or Copiapó, where a mean rainfall of about 15 mm. (0.6 in.) prevails.

The rainfall increases rapidly to the south, being 141 mm. (5.6 in.) at La Serena (30°); 500 mm. (19.7 in.) at Valparaíso (33°). The increase southward is still fairly regular reaching 2,707 mm. (107 in.) at Valdivia (39° 50′). From there south, the rainfall is more or less uniform except for local modifications with the striking maximum of 5,379 mm. (216 in.) for south Chile at Balúa Felix (53°).

The Chilean rains definitely come from the west. The western Andean slopes are wetter than the valley areas in all latitudes, and this is very noticeable even on the Andean slope of the northern desert region, where a rainfall map, however, shows all of Chile north of 31° with less than 10 inches. This dry area thrusts a finger down the central valley nearly as far south as Santiago. The 10 to 20 in. rainfall area, whose southern coastal limit is at Valparaíso, sends a strong arm down the valley nearly as far as Concepción, with a rain belt on either side of 20–40 in. and with a belt along the western slope of the Andes, overlooking the beautiful agricultural valley, of 40 to 80 inches. This belted arrangement is still more marked in the southern rainy section. The various islands and embayments show a rainfall of 80–200 in., the mountainous area directly to the east has a precipitation of over 200 in., while over in Argentina the rainfall gradually decreases again to less than 20 in.

Irrigation is needed throughout the central valley, not only because of the low rainfall but more especially because the greater part occurs in the winter. This discrepancy becomes less marked from north to south. At La Serena over 98% of the rain comes in the six winter months and 82% in the three colder months. The percentages at Santiago for the same periods are respectively 90 and 73; for Concepción 83 and 61.

Even at Punta Arenas 61% of the precipitation is during the six winter months. This seasonal distribution has given Chile an irrigated agriculture with an intensive rather than an extensive use of the land and with the climatic life of the Mediterranean.

In general, for its latitude, the temperature is low. The cold Humboldt current, which strikes Chile in the vicinity of 40° S., flows northward along the entire coast, and keeps the temperatures down and very uniform. The average summer temperature, even at Arica, does not rise above 75° F. Similarly the mean at Iquique is only 66° F., and at Antofagasta 65° F., although southward the temperature is somewhat lower as at Valparaíso, where it is only 58° F. At the latter place, the mean monthly temperature varies from 63.5° F. in summer to 52° F. in winter, and the thermometer seldom rises to 85° or falls below 38°. Santiago at an altitude of 1,740 ft. has recorded extremes of 96° F. and 25° F., and on rare occasions snow falls in the city. At Valdivia in the southern end of the central valley, January is the warmest month with 61.5° F. and July the coldest with 45° F. Because of the winter rainfall and the attendant cloudiness, the sensible winter temperatures are somewhat lower than the records indicate. But there is no doubt that the main inhabited parts of Chile enjoy some of the most healthful climates of South America.

(H. J. Bn.; W. H. Hs.)

Vegetation.—With more than 70% of Chile mountainous, with altitudes from sea level to more than 20,000 ft., with rainfall from practically nothing to more than 200 in. annually, and temperatures from very hot to cold, it is readily understandable that the flora is remarkably diverse. Three main plant zones, correlated chiefly with changes of altitude and climate, are evident.

(1) An almost rainless desertlike area, between 19° and 30° 50′. The Chilean coast from the Peruvian border to 20° S. lat. is nearly barren, more nearly approaching an absolute desert than any other part of the world. South of 20° the heavy winter fogs of the coastal hills account for a seasonal flora, prominent in Antofagasta and Atacama provinces. Between 24° and 26° 50′ there are four main types of vegetation in the coast range, varying from drought-resisting desert shrubs, such as *Chuquiragua ulicinia* and cacti, above and below the fog belt, to a more varied plant formation within the fog belt, containing among other species various cacti, *Oxalis gigantea, Proustia tipia,* and *Alstroemeria violacea.*

(2) "Mediterranean" zone, between 30° 50′ and 37°, having dry summers and rather rainy winters. This zone is diversified, and the flora varies with the altitude. Near sea level *Solanum maritimum* is common. Up to 2,500 ft., characteristic plants are *Crinodendron patagua* and *Bellota miersii.* Over large areas in these lower altitudes species of *Adesmia* and *Acacia* are common. On certain favoured slopes Quillai (*Quillaja saponaria*), *Cryptocarya,* and *Lithraea,* among others, are found. Other plants at this altitude favour running or seasonally dry streams. Up to 4,500 ft. *Valenzuelia* and other shrubs grow. Below the snow line (about 14,000 ft. in central Chile) are developed the conspicuous cushion or mound plants, chiefly *Azorella* and *Laretia acaulis.* Many spring-flowering (October and November) plants, belonging to such genera as *Valeriana, Anemone, Cardamine, Libertia,* and *Oxalis,* are found in this zone.

(3) A humid area from 37° to 56°, between Concepción and Tierra del Fuego, with rain the year round in some places exceeding 200 in. There is developed a dense, rich, temperate, rain forest slightly south of Valdivia to Magellan strait. Several species of false beech (Nothofagus), nine kinds of conifers, including *Saxegothea, Libocedrus, Dacrydium, Fitzroya, Podocarpus, Araucaria,* and *Pilgerodendron,* many of the myrtle family (Myrtaceae), *Lomatia, Embothrium,* and *Weinmannia* constitute some of the principal trees in these forests. A motley variety of vines, shrubs, ferns and mosses abound, while in more open parts of the rain forest are found solid thickets of the wild bamboo, *Chusquea.*

Many distinct genera and species of plants are known only from Chile. Many of the Chilean plants are Andean in origin and relationship, others are subantarctic. Examples of relict and isolated assemblages of plants occur in the flora, suggesting correlation with past climatic and geological changes and events.

(J. A. Sk.)

Fauna.—Except at the extreme south, where low passes lead to Patagonia, and at the north, where the deserts of both coast and highland merge with those of Peru and Bolivia, Chile is cut off from the rich life of South America by the barrier of the Andes, which extends north and south for hundreds of miles with scarcely a pass below the snow line.

The larger Chilean mammals are the puma and guanaco, the Andean wolf and the *huemul* (a large deer), the foxlike *chilla,* and two kinds of wild cats. The mountain rodents include the almost extinct chinchilla. The South Chilean forest has distinct types of marsupials (especially *Rhyncholestes*), Darwin's fox, and the little spike-horned pudu, smallest of deer. Though rich in small birds, Chile does not have many of the more conspicuous South American bird types.

The Chilean bullfrog, *Calyptocephalella,* with a bony casque, is regularly eaten. The tiny Darwin's frog, *Rhinoderma,* is remarkable in that the male takes the developing eggs into his enlarged vocal pouch, where they transform into tiny froglets. The native fresh-water fishes are extremely few. The successful introduction of North American trout into the lakes of southern Chile has made them attractive resorts for fishermen. (K. P. S.)

Population.—Quite commonly Chile is spoken of as a "white man's country." This is true when compared with the plateau countries to the north, but the qualification is more a matter of class than of blood. There was abundant opportunity for mis-

cegenation during the colonial period as the fierce Araucanian Indian remained unconquered for three centuries and the conflict with him called for an endless succession of Spanish soldiers, who in turn left in their wake a large number of half-breed children.

From such unions came the foundation of the Chilean race. The mixture occurred so long ago that its results are now expressed in racial unity and common characteristics and are quite unnoticed in the country itself.

In the forested region south of the Bío-Bío river are the Araucanian Indians who proved such valiant and unconquerable foes during both the Inca and Spanish regimes. Their definite overthrow as an independent people came only in 1882 when seasoned troops from the battlefields of the north pushed through the *frontera* and put an end to their resistance. The Araucanian strain in Chilean blood is considerable although not so noticeable as the blood of other tribes for it has not resulted in deterioration. Pride in the Araucanian heritage is reflected even in the national anthem. About 90% of the Indians (127,151 in 1952) live in the provinces of Malleco and Cautín.

Beyond lie Valdivia and Llanquihue. It is in this region that German colonists of the mid-19th century encountered extraordinary hardships. But they introduced much-needed handicrafts, iron- and woodworking, tanning, shoemaking and the like, and soon drew large numbers of Chileans to their settlements. The Germanization of south Chile has not been a matter of sheer numbers, but results from a far-reaching cultural influence that if more widespread might prove a great blessing.

In the extreme south one still encounters some remnants of the Fuegians, an indigenous people of extremely low culture, and in the north the Changos may represent survivors of an earlier native stock. In other parts of the country a plentiful sprinkling of English, Irish and Scotch names denotes an infusion of northern European blood, while Spaniards, Italians and Slavs bespeak a continued connection with southern Europe.

Chile, however, has never attracted a large immigration, and the influence of immigrants in the composition of the Chilean people has not been large.

The 1952 census showed a population of 5,930,809 (2,911,129 men and 3,019,680 women) as compared with 5,023,539 in 1940, 4,287,445 in 1930 and 3,731,573 in 1920. The density of population per square mile in the whole country was 20.7 in 1952, but there was a wide variation in density among regions. The northern desert region, with more than one-third of the total area, had 6½% of the population and a density of less than 4 per square mile. On the other hand the central Mediterranean region, with only 18% of the national area, had 65% of the total population and a density of 76 per square mile.

The mainland forest region, with 13% of the area, had 26% of the population and a density of 38 per square mile, but the archipelagic zone of the forest area, with 27% of the total area, had 2% of the population and a density of little more than 1 per square mile. Atlantic Chile, with 7% of the area, had 1% of total population, most of its inhabitants being concentrated in the city of Punta Arenas.

Chile has one of the highest birth rates in the world. Before 1930 the rate averaged 40 per 1,000 with only minor fluctuations. After 1930 a slow decline set in which was maintained with small variations, the 1946, 1950 and 1951 rates of 32.4 per 1,000 being the lowest recorded in the 20th century. There was an increase to 33.5 in 1952 and 36.1 in 1953.

The high birth rate is characterized by a large number of illegitimate births. A record peak of 39.1% was recorded in 1917; thereafter there was a progressive decline to a record low of 17.8% in 1953.

The death rate showed a progressive decline after 1900. The average rate per 1,000 in 1905–09 was 32.5, while in 1930 it was 24.7; in 1940, 21.6; in 1950, 15.7; and in 1953, 13.2.

The increase in Chile's population was accompanied by a strong trend toward urbanization. The 1952 census classified 60% of the population as urban and 40% as rural; the corresponding percentages in 1940 were 52 and 48.

Major cities (1952 census) were Santiago, 1,348,283; Valparaíso, 218,829; Concepción, 119,887; Viña del Mar, 85,281; and Antofagasta, 62,272.

TABLE I.—*Provinces* and Population*
(Census Figures of 1930, 1940 and 1952)

Province	Area in sq.mi. 1930	Population Census of 1930	Area in sq.mi. 1940	Population Census of 1940	Population Census of 1952
Aconcagua	5,798	463,544		118,049	128,378
Antofagasta	47,502	178,765		145,147	184,779

Valdivia	10,731	236,115		191,042	242,617
Valparaíso	..	..		425,065	498,186
Antárida	..	..		..	87
Total	286,322	4,287,445	286,306	5,023,539	5,930,809

*This table represents the distribution of territory established in 1928 and 1940. In 1928 the former province of Valparaíso was annexed as a department to Aconcagua and the former province of Llanquihue was made a department of Chiloé, while the territory included in the old provinces of O'Higgins, Curicó, Linares, Arauco, and Malleco was divided among the neighbouring provinces. At the same time the new territory of Aysén was created from the lower part of Llanquihue and upper Magallanes. The populations here given for 1930 are for the provincial boundaries then in force.

Government.—Technically Chile is a unitary republic with responsibility centred in the president, who is elected for six years and cannot succeed himself. After experimenting for more than 30 years with a pseudo-parliamentary government, Chile in 1925 reverted to the presidential type.

The constitution which was adopted in that year provides for direct elections, for suffrage and citizenship without class distinction, for the separation of Church and State and for an independent president.

The validity of a president's election is finally determined by a special tribunal made up of former presiding officers of the senate and chamber of deputies and members of the supreme and appellate courts.

The president selects the members of the supreme court from a list of five proposed by the court itself, designates members of the courts of appeals, of which there are eight, from lists submitted by the supreme court, and appoints judges of first instance from lists submitted by the court of appeals in the jurisdiction concerned.

The president cannot remove judges but he is empowered to transfer them, when necessary, within the jurisdictions to which they belong. Judges are removable by a two-thirds vote of the supreme court.

The president names the *intendentes* of the provinces, the governors of departments, and *alcaldes* in municipalities or communes of more than 10,000 inhabitants. He also has the power to remove these officials and indirectly controls their subordinates. The constitution provides for provincial elective assemblies, but so far no measures have been taken to carry out this provision or to give greater power in local affairs to the *intendentes* and governors. The taxpayers are empowered to name communal committees (*juntas de vecinos*), non-political in character, who advise in local administrative and economic matters. Since 1935, women and foreigners residing for 5 years in the country may vote in

municipal elections.

Congress consists of a senate and chamber of deputies. The former is composed of 45 members, five from each of the nine groups of provinces into which the republic is divided. Each senator holds office for eight years, and half the seats are renewable at the end of four years. The chamber of deputies numbers 132 members, one for each 30,000 inhabitants or major fraction. Electors are registered citizens over 21 years who are able to read and write. The ordinary session of congress lasts from May 21 to Sept. 18. It passes on the budget but the president may increase or decrease items within the limits therein prescribed, but congress may by a two-thirds vote pass a bill over his veto. Members of the cabinet are ineligible for seats in congress, but may speak in its sessions. They are subject to impeachment by congress and to removal from office for cause.

Credit and Finance.—The monetary unit is the peso, divided into 100 centavos. The peso was established at a gold valuation of 6*d*, or 12.17 cents, U.S. currency, in July 1931. By agreements with the International Monetary fund it was officially revalued on Dec. 18, 1946, at 3.22 cents, or 31.1 pesos to the dollar, and on Oct. 7, 1953, at 0.91 cents, or 110 pesos to the dollar. Effective Nov. 17, 1954, the official rate for most transactions was changed to 0.5 cents. The free market (curb) rate was 0.33 cents on Dec. 31, 1954. Foreign exchange control was initiated in July 1931 and various economic factors after that date fostered the growth of an intricate system designed to meet the peculiar needs of the Chilean economy. Beginning in 1947 most operations in foreign exchange were carried on within the framework of an annual foreign exchange budget prepared by the National Foreign Trade council in collaboration with the Central bank.

Chile's physical expanse has always made the collection of public revenue difficult and costly. Moreover, the dominant landowning class resisted any attempt to tax the land and its production and the remainder of the population had little to be taxed. As a result, import and export taxes were relied upon from an early date as the two principal sources of public revenue. From 1880 to 1930 nitrate taxes accounted for more than 40% of all public revenue and up to 1917 they produced 50% or more of the national revenue. With the growth of competition from synthetic nitrates in the 1920s, export taxes were lowered but still accounted for 25% of the revenue. As a result, the collapse of foreign trade in the early 1930s seriously affected public finance.

Over the next 20 years the national revenue was slowly placed on a broader base, and by 1953 the distribution was approximately as follows: internal direct taxation 25%; internal indirect taxation 45%; customs duties 5%; national services 3%; miscellaneous 22%. Table II shows ordinary public revenue and expenditure for five years. Ordinary state expenditure by ministries was constituted as follows in 1953: commerce and economic development 31%; education 14%; public works and transport 13%; defense 13%; health 10%; interior 9%; others 7% (including presidency, congress, foreign relations, justice and agriculture).

*Budget estimate.
Source: Servicio Nacional de Estadistica.

The total budgetary deficit for the years 1950 through 1953 was 19,588,557,487 pesos.

The external debt of Chile grew very slowly during the 19th century. During the first Ibáñez regime (1927–31) large amounts, mostly U.S. dollars, were borrowed for public works programs. With the onset of the depression and the loss of foreign trade, Chile was unable to meet these obligations and its first default on its foreign debt occurred in 1931. Under Gustavo Ross, as minister of the treasury after 1932, service on part of the foreign debt was resumed. Favourable economic conditions during World War II permitted partial liquidation of the debt and thereafter the income from the Nitrate and Iodine corporation and the tax on copper companies made further reduction possible. Between 1934 and Dec. 31, 1953, the debt was reduced from £29,600,000, $264,600,000 and 120,600,000 Fr. Swiss to £17,440,974, $106,595,500 and 85,832,400 Fr. Swiss. Large development expenditures, however, sharply increased the internal debt; it stood at 10,363,370,454 pesos on Dec. 31, 1953.

The Central bank was established in 1925 upon the advice of the Kemmerer commission. It is modelled on the U.S. federal reserve system and is the only bank of issue. Of its capital, 10% is owned by the treasury and the balance, in varying proportions, by other banks, domestic and foreign, and the public. It was given control over the lending powers of other banks in June 1953.

Supervision of insurance companies is exercised by the superintendency of insurance, corporations and stock exchanges, which is part of the ministry of the treasury. All insurance companies must obtain authorization to do business; authorization is not granted to foreign companies not already doing business in Chile.

Foreign Investment.—Although a relatively small country, Chile has attracted sizable amounts of private foreign investment. In the last part of the 19th and the early years of the 20th century there was a growing amount of foreign investment in the exploitation of mineral resources, particularly nitrate, and in railway construction. The immediate post-World War I period was marked by large investments in copper mining. With the growth of national sentiment in the early 1930s, foreign-owned firms became the target of increasing government controls, but foreign investments nevertheless continued to expand both before and after World War II. In 1929 U.S. direct investments were valued at $422,600,000; in 1936, $483,700,000; in 1943, $328,300,000; in 1950, $540,100,000; and in 1953, $666,000,000. Of U.S. investments in 1950, mining and smelting accounted for $350,600,000; transportation, communications and public utilities $137,000,000; and manufacturing $29,000,000. At the end of 1953 Chile was fourth in Latin America with respect to the amount of U.S. investment. Other direct foreign investments approximated $144,000,000, in large part British, at the end of 1950. A considerable reduction in British investments took place during World War II. The most important post-World War II U.S. investments were the Chile Exploration company's construction at Chuquicamata of a new plant to utilize copper sulphide ores and the Bethlehem Steel company's development of the iron ore reserves of Romeral.

Development Corporation.—The Chilean Development corporation (Corporación de Fomento de la Producción de Chile), established in 1939, presents an outstanding example of successful national planning aided by international co-operation. Under its basic law it is charged with directing the economic development of the country. Freed of customary controls by government departments, it is directed by a presidentially appointed council which is presided over by the minister of economy and commerce. In practice, its projects were financed by foreign loans matched by the corporation's funds, grants from the government and private Chilean capital. From its inception in 1939 until the end of 1952 it received more than $125,000,000 in credits from the U.S. Export-Import bank and $17,300,000 from the International Bank for Reconstruction and Development, Chile being the first country to receive (in 1948) facilities from the latter bank for development, as opposed to reconstruction. Almost one-half the credits were used for construction of the Huachipato steel plant; the remainder was used in a wide range of projects, including agricultural mechanization, hydroelectric plants, the Romeral iron mine, road-making equipment, irrigation projects and a rayon plant.

Education.—Chilean education in the colonial period was limited and was conducted by the church. The first public education system was organized around the middle of the 19th century. A program of school building was inaugurated during the prosperous years of the 1880s and was continued into the 20th century, but it was not until 1920 that primary education between the years of 7 and 15 was made compulsory. From 1900 to 1920 the number of elementary schools rose from 1,547 to 3,148 and by 1947 the number had increased to 5,635.

At mid-20th century the administration of the school system

was highly centralized under the ministry of education. State-authorized private schools continued, however, to play an important role. The system was organized along three separate levels—primary, secondary and university. Between 1937 and 1951 enrolment of primary pupils increased from 587,108 to 721,879; of the latter, 100,934 were enrolled in private schools. Attendance as a percentage of those of school age was only 51.1 in 1948 and a high percentage abandoned school after learning the rudiments of reading and writing, which had the effect of producing a high proportion of semiliterates. This tendency was greater in the public than in the private schools and also among boys than girls. Out of each 100 who started the first grade in 1943, only 19 were in the sixth grade in 1948. Illiteracy was estimated at 49.7% in 1920, 25.2% in 1931 and at about 20% at mid-20th century.

In 1952 there were 101 public secondary schools with 54,666 students enrolled and 231 private schools with 31,512 students. In 1949 another 67,000 pursued agricultural, vocational, industrial, technical, commercial, artistic and nursing courses. Normal-school enrolment was 3,583 in 1948.

The University of Chile, Santiago (founded 1842), is the official university; it had 6,903 students in 1950, about 10% of whom were foreigners. The Catholic University of Chile, Santiago (founded 1888), had 1,914 students and the Catholic University of Valparaíso, 642 students. The University of Concepción, which has many features analogous to modern English universities, had 1,433 students. The privately endowed Santa María Technical university, Valparaíso, offered excellent technical and engineering courses comparable to those of the pre-World War II German universities.

In 1949 Chile had 39 daily newspapers with an aggregate daily circulation of 456,000. There were in all 318 newspapers and 676 magazines. Motion-picture theatres numbered 410 in 1951 with seating capacity of 300,000.

Social Conditions.—Labour organizations before the 20th century were of the beneficiary type, the pioneer being the Typographical union organized in 1853. The extractive industries gave impetus to the formation of a formal labour movement in the last years of the 19th century, and by 1903 workmen's associations or trade unions (*sindicatos*) had about 63,000 members centred in the province of Valparaíso. This number grew to 92,000 by 1910 and in 1909 the Labour Federation of Chile was organized. It adhered to the third international in 1921 and much of its program, which as adopted in 1919 was frankly Communist, was embodied in the social legislation of 1924–26. After 1920 unions abandoned the policy of abstention from politics.

Conditions in the early 1930s stimulated the conversion of the labour movement into a popular mass organization. In 1936 rival labour organizations formed the Chilean Trades Union congress (Confederación Nacional de Trabajadores de Chile) which included 50% of Chilean industrial workers and a larger proportion of miners and became a strong supporter of the popular front. After World War II a rift, brought into the open by the general strike of 1946, occurred between Communist and other elements in the confederation, with the coal-mining unions supporting the Communist element, the nitrate and railway workers' unions being more or less divided and the copper-mining unions and most of the important manufacturing unions of Santiago and Concepción supporting the Socialists. The confederation withdrew from the Latin American Federation of Labour (C.T.A.L.) in June 1947 on the ground that that organization had succumbed to Communist influence, and Bernardo Ibáñez, a founder of the confederation, was elected president of the anti-Communist Inter-American Federation of Labour in 1948. At mid-20th century the majority of Chilean industrial labour was represented by well-organized and highly aggressive unions.

The progress of the Chilean labour movement was not accomplished without violence. There was a bitter general strike at Santiago and Valparaíso early in the 20th century and the Iquique strike in 1907 resulted in the death of 1,000 persons. Strikes were prevalent in the 1920s and 1930s, and severe post-World War II inflation prompted many crises. In the latter period the operations of a number of foreign interests, including the copper and nitrate companies, were seriously hampered by protracted labour disputes, work stoppages and strikes. In 1953 there were 208 strikes, legal and illegal, involving 123,103 persons. The Labour code provided that no work stoppage could occur in any establishment employing ten or more workmen or employees until the code's provisions for conciliation were exhausted.

Chilean labour and social legislation is among the most extensive in Latin America. Although there were some earlier enactments, labour legislation had its formal beginnings in the decree law of Sept. 8, 1924, which with supplemental legislation was codified as the Labour code of 1931, the first labour code to be promulgated in Latin America. The code regulates in detail employer-employee contracts, hours and wages, vacations and holidays and workmen's compensation. It provides that at least 85% of all employees of any one employer must be Chilean and that at least 85% of any one employer's payroll must be paid to Chileans. The code also provides for the compulsory sharing of profits by labour. It places on the employer the responsibility for work accidents and diseases except those caused intentionally, those caused by exterior *force majeure* and those not arising in the ordinary course of employment. Employers may relieve themselves of responsibility by insuring either with the State Workmen's Compensation fund (Caja de Accidentes de Trabajo) or with a private insurance company authorized to do business in Chile.

The Chilean national system of social insurance, initiated in 1926, covered at mid-20th century virtually the whole working population under the aegis of a number of organizations of social prevision which are under the general supervision of the ministry of health, social insurance and social assistance. The basis of the system is a compulsory *caja*, or guild structure, related to the type of employment. The system is financed by employer, employee and state contributions. The law applicable to manual workers provides sickness, invalidism and old-age insurance; that applicable to salaried employees also provides for other benefits, including family allowances, unemployment benefits, dismissal wages, medical benefits and borrowing privileges.

The largest *caja* is that covering manual workers (Caja de Seguro Obligatorio), which had 1,050,000 active participants in 1952. The next largest are those covering salaried employees of private commercial, industrial, agricultural and mining companies (120,000) and state, semistate and journalistic employees (84,000). Others cover the armed forces, police, municipal employees, merchant marine and railway workers.

At the end of 1952 all the *cajas* had total assets of 27,537,835,359 pesos, of which 7,553,446,133 pesos represented mortgage investments and 5,906,193,178 pesos, investments in real estate. Total receipts in 1952 were 13,428,079,638 pesos; expenditures, 8,987,332,046 pesos.

Considerable progress was made after 1925 in the fields of public health and sanitation and as a result there was a sharp reduction in the death rate. In 1951 Chile had a total of 3,251 physicians, or 1 per 1,800 inhabitants, as compared with a rate of 1 per 750 inhabitants in the U.S. The Chilean rate was surpassed in South America only by those of Argentina and Uruguay. In 1951 there were 33,738 hospital beds.

Mining.—At mid-20th century Chile was the leading mineral-producing country in South America, and the mineral extractive industry largely determined the financial and economic policy of the nation. The industry dates back to colonial days, but the modern history of the development of mining is predominantly the history of nitrate and copper operations. Nitrate was predominant from the 1880s until the early 1930s when competition from

synthetic nitrate and the depression brought about a decline in importance. Thereafter, copper was the predominant force in the industry.

Nitrate.—Chile has a complete monopoly of the production of

natural sodium nitrate acquired as a result of the acquisition of the northern desert area through the War of the Pacific (1879–83). The deposits, which vary considerably from area to area both in thickness and depth, occur from Arica to Copiapó in the central zone between the coastal plateau and the Andes. The beds vary in width from 5 to 40 mi. and occur at altitudes from 4,000 to 9,000 ft. The ordinary workings are by the open-pit method, and most of the *caliche*, or ore, is mined by hand methods, although electrical equipment is also used. The Guggenheim process of treating ore, introduced in 1926, permitted a considerable reduction in costs and a more complete recovery of nitrate than the old Shanks process that had prevailed from 1884.

The origin of these immense deposits is more or less conjectural. The theories roughly fall into two groups, the organic and the inorganic. The theories of origin through organic means are: (1) from seaweed; (2) from guano; and (3) from fixation of atmospheric nitrogen by bacteria. However, none of these theories is taken very seriously at the present time. The inorganic origin has been attributed to: (1) the electric fixation of atmospheric nitrogen; and (2) to the concentration of the nitrates coming directly from tuffs and lava flows. The latter postulates, probably the more scientific, present fewer difficulties. Of this group, two theories stand out most prominently. The one (J. T. Singewald, Jr., and B. L. Miller, "The Genesis of the Chilean Nitrate Deposits," *Econ. Geol.*, xii, 1917) "is that the nitrate deposits have resulted from the accumulation, by means of evaporation of the minute nitrate content of the underground waters of the region. In other words, they represent a sort of efflorescence of soluble salts out of the ground water." The other (W. L. Whitehead, "The Chilean Nitrate Deposits," *Econ. Geol.*, ix, 1920) and later suggestion is that the source of the salts is from the Mesozoic rocks of the region which in extent correspond remarkably with the nitrate fields. Ammonium salts were probably sufficiently common in the volcanic rocks of the region to account for the present deposits. The process of reconcentration, through oxidation with alkaline earth, has been going on since early Pliocene time. Under desert conditions the salts derived from sources on steep slopes and hilltops were carried down by dews, fogs or infrequent rains to be deposited during evaporation in the gravels below. There in periods of high humidity, sodium nitrate, a deliquescent substance, was separated from the accompanying sodium chloride and sodium sulphate, to be precipitated during dry weather lower in the gravel.

The importance of these deposits to Chile can be gauged with little certainty. It has been estimated that between 1880 and 1910 Chile derived from the export tax on nitrate alone an average annual income of $10,000,000 gold and up to 1920 one of twice that amount. For many years this nitrate trade constituted more than half the total value of its exports, and the tax thereon of $10.60 U.S. gold per ton collected by the government constituted not only the largest item of its revenue, but also for some years exceeded all other revenues combined. The prosperity of the whole country and the financial condition of the national treasury were to a very large measure determined by the condition of the nitrate industry.

Nitrate production increased steadily to a peak of 3,000,000 tons in 1914 and in 1910 Chile produced 64% of the world's nitrogen requirements. Thereafter, the industry began increasingly to feel the effect of competition from synthetic nitrates, although this was offset somewhat by the development of low-cost production processes. However, the world depression of 1930 and subsequent collapse of world trade had a catastrophic effect on the industry. As a result, the government in 1934 instituted a monopoly over the production and sale of nitrate through the vehicle of the Chilean Nitrate and Iodine Sales corporation. This organization determines the amount of nitrate to be produced each year, allocates the production among the producing companies, fixes sales prices and concludes all sales of nitrate and iodine. By joining a world cartel it succeeded in increasing sales abroad and with the general improvement of market conditions in the 1940s the industry recovered somewhat. In the mid-1950s, however, it had a doubtful future. Chile is the world's largest supplier of iodine, which is a by-product of the nitrate industry. The supply varies with the quantity of nitrate treated.

Copper.—Chile also has rich and abundant low-grade copper deposits. Some of the richer ores were worked by the Spaniards as early as 1601 and by the Indians long before. In the latter half of the 19th century Chile was a leading copper centre of the world, in 1876 producing 38% of the total supply.

With the development of the copper deposits in the United States, Chilean production fell off to only 4% of the world total in 1906. It surpassed nitrate in importance after 1932, but the depression of 1930 and the discovery of new ore bodies in Africa caused a period of stagnation, which was ended by market recoveries in the late 1930s and the advent of World War II. Copper exports reached a record peak of almost 500,000 tons during the war. In the postwar period the industry was faced once again with the problem of expanded production and contracting markets. It was also hampered by high taxes and government regulation. More than 95% of Chilean copper is produced by U.S. companies operating at three centres: one in the north at Chuquicamata; another near Rancagua at El Teniente; and the third at Potrerillos near Chañaral. The Chuquicamata deposit has the greatest reserves known to exist; they were estimated at mid-20th century at 1,000,000,000 tons of 2% ore.

Iron ore.—Chile has numerous large high-grade iron-ore deposits, the three best known being El Tofo, Romeral and Algarrobo, all in the coastal zone. El Tofo, the first deposit to be developed, was worked by a subsidiary of the Bethlehem Steel corporation. Shipments to the U.S. of the ore, which runs about 60% iron, began in 1922. The mining and loading on steamers of the ore is considered a model of efficiency. Shipments were suspended during World War II. In 1952 Bethlehem also began working the El Romeral deposit; shipments were made via Guayacán, near Coquimbo, for the benefit of both the domestic and U.S. market.

Other Minerals.—Petroleum was discovered late in 1945 at Cerro Manantiales and San Sebastián on Tierra del Fuego; commercial production began in 1950. Development of the field entailed the construction of a 46-mi. pipeline from the producing area to a port and of submarine lines at Bahía Gente Grande (Caleta Clarence) for loading oil at deepwater stations. Production and refining is under the control of the Development corporation.

Chile is rich in sulphur deposits which occur in the Andean cordillera from the extreme north to the southern limits of Mediterranean Chile.

The coals of Chile are noted for their quantity rather than their quality. They occur on the coast south of Concepción and are of Tertiary age. They vary considerably in quantity, improving with depth. The product has been described as second-class steamer coal, on the average 25% inferior to the Welsh product. There are four principal coal fields in the vicinity of the Bío-Bío, of which the most important, Coronel and Lota, are worked under the sea by means of inclined drifts (*chiflones*) on the longwall system. In addition there is a small lignite deposit near Magallanes mined only for local use.

Alluvial workings for gold were long a feature of the mining

industry, but at mid-20th century the emphasis was on the exploitation of lode gold and the extraction of gold from copper ore. More than 50% of the country's silver production also came from copper ore. Silver mining was concentrated in Antofagasta province, near Taltal. Valuable molybdenum concentrates are recovered from copper refining by differential flotation at the El Teniente copper mine. Other mineral resources included mercury, calcium borate (source of borax), phosphates, kaolin, limestone, quartz, barium sulphate, gypsum and large reserves of manganese ore.

Agriculture.—The agriculture of Chile is confined almost wholly to the central valley. The available productive land is extremely limited, the amount devoted to cereals and other food crops being estimated at not more than 4% of the total area of the country; orchards, vines, planted woodlands, grasses and alfalfa (lucerne) occupy a somewhat smaller area; and the natural pasturage occupies a smaller area still. This 10% or 12% of the area, together with the 20% to 22% in natural forests and woodland, mostly in southern Chile, make up the productive land—about one-third of the total area of the country.

By far the major part of the cropland is made possible only by irrigation, which was practised in limited areas of northern Chile even during prehistoric times. The chief areas now under irrigation lie along the river terraces within the cordillera, upon the piedmont to the west or within the central valley. The available streams from the Loa to the Bío-Bío are the chief sources of water. Some of the irrigation projects are of long standing and on a large scale, and carry water in canals more than 100 mi. besides furnishing extensive electric power. Many of the undertakings are privately owned, others belong to associations and others, some very large, were financed by the government.

Although agriculture in the central valley lays the foundation for the social and political structure of the country and affords a large share of the products for local consumption, it has little influence on trade balances. Socially the bulk of the people are organized around the large feudal estates and suffer little change in condition whether crops are good or bad. The owner may be more or less affluent from year to year, but this adds little to his comforts or discomforts, and he always remains on the social and political register of the country. In the northern valleys maize (corn) is the chief food crop and besides there is a great variety of subtropical fruits. The best developed type of feudal estate may include about 250 ac. of irrigated fields and 2,000 ac. or more of hillside land, which offers excellent range for livestock during the rainy season. These *propriedades agricolas* are mixed farms producing a large variety of grains and fruits and alfalfa, some horses and a larger number of cattle and sheep, but never many hogs. The growing of livestock on irrigated land, however, is not profitable. As a result Chile, with less than half the cattle of Cuba, became dependent upon Argentina for part of its meat supply.

The central valley, which is similar to that of California, favours the growing of fruits, and apples, pears, peaches, apricots, plums, prunes, cherries, table grapes, raisins, oranges, lemons and figs are produced in commercial quantities. Markets have been developed in the U.S. and Europe.

Chile is an important wine producer. In 1952 there were 32,154 vineyards covering 97,603 ha.; production by 27,129 vineyards harvesting grapes from 84,752 ha. was 58,100,000 gal. (1942–50 average: 81,900,000 gal.). Production is concentrated in the central valley, with the provinces of Santiago, Talca and Linares accounting for more than one-half the national total.

In the second quarter of the 20th century agricultural and pastoral production increased 30% over the 1923–27 level. Most of the increase took place in the 1930s and thereafter there was little change. There was, however, a change of emphasis, with the production of beans, peas, lentils, fruit and wine increasing and that of fodder barley, meat and wool tending to decline.

The waters off the coast of Chile are rich in fish. Production in 1953 included 87,075 metric tons of wet fish and 19,663 tons of shellfish. Between 1944 and 1953 there was an almost uninterrupted increase in production which in 1953 was three times that in 1944. Talcahuano and ports in Arauco and Tarapacá are the principal bases for the industry.

Southern Chile has vast forest resources, but at mid-20th century they were relatively unexploited. Nevertheless, development had permitted the creation of a considerable export trade, notably in pine, laurel, beech and other woods, and the satisfaction of most domestic needs, once-substantial imports, largely from the U.S., having been almost entirely eliminated. A U.S. forest service mission estimated in 1943 that the forested area covered 40,000,000 ac., a large part of which had to be discounted because of inaccessibility or the nature of the woods. It has been estimated that forest fires destroy three times as much timber as the country uses annually. Two-thirds of forestry production comes from the provinces of Cautín and Valdivia, which have the most accessible and valuable stands.

Manufacturing.—Chilean manufacturing industries produce principally for the domestic market, which is limited by low per capita purchasing power and also by inadequate transportation and communications facilities. Industry made important advances after 1930 and by the mid-1950s it supplied all of Chile's essential needs for some articles, including woollen textiles, footwear, paper other than newsprint, cement, explosives and glassware, and an increasing proportion of other items, including cotton textiles, clothing, paint, iron and steel and some building materials.

The basic pattern of Chilean industry was set prior to World War I, when sugar refineries, food and beverage industries, woollen and cotton mills and a cement plant were already in existence. The early and middle 1930s saw a considerable expansion of industrialization, and in the ten years between 1928 and 1938 the index of factory production increased 66%. The expansion was promoted by a desire to alleviate the severity of the economic dislocation caused by the depression and had the twofold objective of helping to free the economy from its dependence on mineral exports and raising the standard of living.

By far the most important landmark in the history of Chilean industrialization was the creation in 1939 of the Development corporation. In the following years it engaged in a program of widespread industrialization which was aided by high protective tariffs and exchange controls. Despite difficulties caused by World War II, industrial production increased 60% between 1937 and

1946. Expansion continued in the immediate postwar period, aided by increased mineral exports leading to increased purchasing power and by the large accumulations of foreign exchange. Thereafter, however, foreign exchange shortages and increasing competition from some lines of foreign goods forced a slackening of the pace from time to time. An important milestone in Chilean industrialization was the coming into operation in 1950 of the Huachipato steel plant near Concepción, which was built under the direction of the Development corporation at a cost of close to $100,000,000.

At mid-20th century almost three-fourths of all manufacturing production was concentrated in the provinces of Santiago (more than 50%) and Valparaíso, reflecting the great concentration of population there. The province of Concepción was third in rank and, with the coming into operation of the Huachipato steel plant, growing rapidly in importance. The remainder of industry was widely scattered. In 1940 there were 4,169 industrial establishments with 116,493 employees; by 1948 these had increased to 5,585 establishments with 296,000 employees. Despite its great advances, manufacturing was still secondary to mining and agriculture in the economic framework of the country.

In order of importance, the food, beverage and tobacco industry ranked first, followed by metals and metal products (including machinery), textiles, chemicals and leather and rubber goods.

Chile is exceeded only by Brazil in South America in the amount of hydroelectric power potentially available. The great bulk of available power is located in the central portion from La Serena to Puerto Montt. The Development corporation made hydroelectric development a central part of its program, and great advances were made. Nevertheless, at mid-20th century power shortages continued to hamper industrial development.

Foreign Trade.—Minerals have played a dominant role in Chilean foreign trade since the mid-19th century, when trade first became an important factor in the economy. Throughout that period there was no fundamental variation in the pattern of foreign trade. In 1913 minerals accounted for 88% of exports and agricultural and pastoral products for 12%; in 1953 minerals accounted for 79%, agricultural and pastoral products for 8% and manufactured and other products for 13%. Within this pattern, however, there were important changes. In 1913 nitrate accounted for 80% of exports and copper for 7%. The decline of nitrate in importance was accompanied by an increase in the importance of copper, which surpassed nitrate in 1932 and thereafter held first place. In 1953 copper produced 57% of exports, nitrate 15% and other minerals 7%. The proportion of agricultural and pastoral products remained fairly uniform, while the proportion of manufactured products grew because of increased processing of foodstuffs and industrial expansion, and in 1953 metallurgical products accounted for 7% of exports. On the other hand, the proportion of manufactured imports decreased in relation to pastoral, agricultural and mineral imports, a change brought about by increased dependence on imported foodstuffs, increased consumption of imported raw materials by industry and the increasing importance of petroleum imports. Leading imports in 1953 were machinery (20%), chemicals and drugs (15%), transport materials (12%), agricultural products (12%) and metallurgical products (9%).

Two world wars and also the change in the character of mineral exports wrought fundamental changes in the geographical pattern of foreign trade. Before World War I most of the exports went to the United Kingdom and other European countries, and the United Kingdom supplied about 35% of the imports, followed by Germany, 25%, the U.S., 17%, and France and Belgium, each 9%. This pattern was dislocated during World War I but was partially restored in the interwar period, although the U.S., largely at the expense of the United Kingdom, became the largest single trading partner, accounting for between one-quarter and one-third of the foreign trade. World War II effected a greater dislocation in the pattern, and trade became predominantly hemispheric in direction. This trend continued during the postwar period, and European nations recovered only a part of their prewar shares. Chief customers in 1953 were the U.S. (64%), Argentina (11%), Germany (5%), the United Kingdom (4%) and Uruguay and Brazil (each 2%); chief suppliers, the U.S. (53%), Argentina (9%), Germany (6%), the United Kingdom (6%) and Peru (5%). As is shown by Table VIII, Chile almost invariably has a favourable balance of trade. Actually, however, on account of large foreign investments in copper and nitrate, the sales of those exports do not return to Chile in foreign exchange the full amount of the selling price, with the result that the apparently favourable balance is often illusory.

Transport and Communications.—Chile is linked with Argentina, Bolivia and Peru by five international rail lines—Arica to Tacna, Peru; Arica to La Paz, Bolivia; Antofagasta to La Paz; Los Andes to Mendoza, Arg. (the famed Trans-Andean line); and Antofagasta to Salta, Arg. (completed in 1948). Internally, the northern two-thirds of Chile is spanned by a 1,450-mi. longitudinal state-owned line running from Pueblo Hundido in the north to Puerto Montt in the south. Numerous short lines connect this line with the coast and the interior. There are also numerous short industrial lines operated principally by the mining companies. The railway system (excluding branch lines and sidings) totalled 5,434 mi. in 1949, of which 3,859 mi. were owned by the state railways. In 1953 the international railways carried 362,000 passengers and 1,053,000 metric tons of freight, the domestic state lines, 22,178,000 passengers and 8,184,000 tons of freight and the private lines, 4,438,000 passengers and 3,626,000 tons of freight.

The mountainous terrain of most of Chile made highway construction quite difficult. Nevertheless, at mid-20th century Chile had a fairly extensive road system aggregating about 32,000 mi., of which 65% was unimproved and only 900 mi. were classified as arterial. The Santiago area and the Mediterranean central valley were best served by roads. Road construction was being pushed in the southern third of the country below Puerto Montt, the southern railway terminus. At the end of 1953 Chile had 47,739 automobiles (an increase of 67% over 1946), 4,501 buses and 38,647 trucks. About 55% of the automobiles were located in the province of Santiago; Chiloé had only 29 automobiles and Aysén, 48.

Maritime communication is of vital importance to Chile, both internationally and internally. Coastal shipping between Chilean ports is the monopoly of Chilean vessels, which operate between all ports from Magallanes in the south to Arica in the north. The extreme north and the extreme south are almost entirely dependent on coastwise shipping for the movement of goods. Of the 10,054 vessels of 19,077,233 net tons entering and clearing Chilean ports in 1953, 7,309 vessels of 7,778,000 tons were Chilean vessels engaged in coastal trade. Valparaíso is the nucleus of the coastal trade and also by far the leading port for imports, followed in that regard by Antofagasta and Talcahuano. Antofagasta and San Antonio are the leading export ports, accounting for more than

50% of the exports by value in 1953; they owe their position to the copper mines at Chuquicamata and El Teniente. Next in importance are Tocopilla, a nitrate port, and Chañaral, port for the Potrerillos copper mine. On June 30, 1953, the Chilean merchant marine had 96 vessels (100 tons and more) aggregating 200,719 gross tons.

The development of air transport was of outstanding importance to Chile because of its geographical situation. Between the late 1930s and the mid-1950s there were enormous increases in traffic on both domestic and international routes. Santiago was the terminus of several international routes, and the number of passengers entering and leaving Chile by air exceeded that of all other means of transport combined. Routes of the National Air Line (L.A.N.) covered the whole length of the country and extended to Buenos Aires. In 1953 L.A.N. carried 133,933 passengers, compared with 18,103 in 1944. Airfields were numerous, but the number suitable for larger four-engined aircraft was limited.

The internal telegraphic service is largely government-controlled; international telecommunication service is provided largely by All America Cables and an affiliate of Cable and Wireless Ltd. The internal telephone service, under control of private companies, is not highly developed; there were 140,769 telephones in 1953, about 90% of which were served by the Chile Telephone company. Commercial radio broadcasting is quite highly developed.

Defense.—Compulsory military service prevails in Chile. Every able-bodied man over 20 years of age is due to receive 18 months' training. Following the months of active service they belong to the first reserve for 12 years and to the second reserve until the completion of their 45th year. At mid-20th century the active army was composed of about 1,900 officers and 18,500 men. It was organized into three army corps, one army division, one cavalry division and one railway regiment.

The influence of the German military system was strong prior to World War II. The air force was organized in 1918 under British instruction. It was strengthened during World War II and is equipped largely with U.S. matériel.

Military, naval and aviation schools are maintained by the government.

The Chilean navy took its rise in 1817 with the capture of a Spanish frigate and brigantine at anchor in Arica bay. This initial success, brought about by a Scotsman, Capt. William McKay, was brilliantly continued during the four years that Thomas Cochrane served Chile and cleared the west coast of Spanish vessels. These operations, loyally supported by the supreme director, Bernardo O'Higgins, made possible the success of José de San Martín in Peru, and left a definite British impress upon the navy of Chile. It was the "Cochrane" which won the naval battle of Angamos in 1879. The officers of the Chilean navy maintain a more aristocratic tradition than the other branches of service. This led the major part of them under their leading officer, Capt. (later President) Jorge Montt, to support congress in 1891 against Pres. José Balmaceda.

In 1954 the Chilean navy had one old battleship, the "Almirante Latorre," a 28,950-ton vessel completed in 1915 and refitted in England in 1929–31, and two modern cruisers, the "Capitán Prat" (10,000 tons) and the "O'Higgins" (9,700 tons), both completed in 1938 and acquired from the United States in 1951. It also had 6 destroyers, 6 frigates and escort vessels, 7 submarines, a submarine depot ship, 6 transports and other ancillary craft. Active strength, including marines and coastal artillery, was about 13,000 officers and men. (I. J. C.; J. W. Mw.)

HISTORY

In the 15th century the Peruvian Indians invaded the country—even then known as Chile—and dominated it as far south as the Rapel river (34° 10′ S.). Their control may have furthered the later conquest by the Spaniards. The latter made their first attempt to occupy the region under Diego de Almagro, associate and subsequent rival of Pizarro. After Almagro's death the conqueror of Peru granted Chile to his favourite aide, Pedro de Valdivia. That invader founded Santiago (Feb. 12, 1541), and after establishing other fortified towns north and south of that centre and east of the Andes, lost his life in a general uprising of the Araucanian Indians, under their celebrated *toqui*, or war-chief, Caupolicán. The greater part of his settlements were destroyed, although La Serena and Concepción remained as the outposts of the future colony to the north and the south, while Cuyo held the same position east of the Andes.

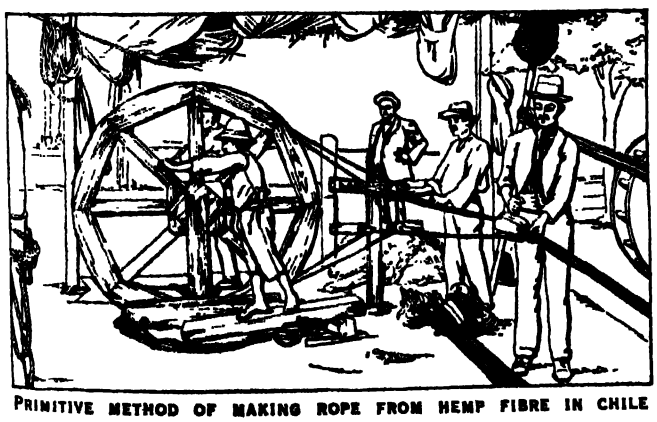
The Colonial Period.—With this inauspicious beginning Chile entered upon its three centuries of colonial history. In such phases of its development as were affected by the administrative and commercial control of the homeland it differed in no wise from its neighbours. Its population took no part in political affairs, aside from membership in the town councils. It accepted ecclesiastical control in its scant educational facilities as well as in spiritual matters. It endured all the vagaries of Spain's trade restrictions, varied by the piratical and contraband practices of its enemies. Chile differed from other Spanish colonies in that its remote position forced upon the people a more thorough isolation, while continued conflicts with the Araucanians tended to harden the settlers, and the scarcity of precious metals turned them toward farming.

By the end of the 17th century this population numbered 100,000. A century later it approached a half million. This included 300,000 *mestizos* (mixed bloods), half as many *Criollos* ("Creoles," *i.e.*, natives of European descent), some 20,000 *Peninsulares* (recently arrived Spaniards, among whom Basque immigrants from northern Spain formed an energetic commercial element), and a smattering of negroes and recently emancipated Indians. This hardy population had progressed far towards racial unity but the *mayorazgos*, a system of transmitting estates by entail, gave enhanced importance to a few leading families. The people, set down in the midst of resources that were barely touched, were stimulated to activity by a bracing climate, but were pitifully handicapped by ignorance, isolation, and the lack of political experience.

Independence and Self-government.—None of the above conditions that hampered Chile in common with its fellow colonies provoked the movement for independence. Nor was this act due to the rise of the United States nor to the French Revolution. It was the intervention of Napoleon in Spain—an act that in 1808 threw each part of the Spanish monarchy on its own resources—that led Chile to take the first halting step toward self-government. This occurred on Sept. 18, 1810, when an open *cabildo* or general town meeting in Santiago accepted the resignation of the president-governor and in his stead elected a *junta* (board) of seven members.

JARS USED IN MAKING WINE

This act divided the people (not including, of course, the ignorant masses) into two general groups. The first, which was composed exclusively of Creoles was headed by the *cabildo*, or town council of Santiago. The *audiencia* headed the second, which largely represented peninsular interests. The former group wished to organize for local protection during the intervention and possibly for more complete self-government thereafter. The peninsulars followed reluctantly, for they preferred to keep intact the existing system which insured them special privileges.



The creole leaders gained their immediate point—a recognized position in the new *junta*, took measures for the defence of the province, opened its ports to general trade, abolished the *audiencia*, when that body encouraged a reactionary uprising, and summoned a national congress. By this time Concepción, under the leadership of Juan Martínez de Rozas, broke away from the conservative leaders of the Santiago *cabildo*. This split enabled an ambitious popular leader, José Miguel Carrera, to dissolve congress, some two months after it finally organized, banish Rozas, and assume dictatorial powers, but this did not occur before congress had assumed administrative control of the colony, broken relations with Peru, abolished slavery, established a press, en-

couraged education and suggested further important steps towards self-government—all in the name of the captive king. Affairs in Chile now assumed the aspect of civil war between those of its people who favoured the former autocracy, as represented by the viceroy of Peru, and those who espoused self-government under a more liberal monarchy. Owing to divisions among the autonomists, who called themselves partisans of Carrera or of Bernardo O'Higgins, who had superseded him, the royalists gained the upper hand at Rancagua, Oct. 7, 1814, and brought to an end that first phase of the Chilean War for independence known as *la patria vieja* (the Old Country).

Two and a half years of repression under the restored government effectually cured the Chilean people of further loyalty to Spain. During this period José de San Martín patiently gathered an army at Mendoza and led it early in 1817 across the Andes. With this force, in which O'Higgins commanded a contingent, he defeated the royalists at Chacabuco, on Feb. 12, and made his associate supreme director of Chile. Their first task was to meet the inevitable counter attack under Osorio, the victor of 1814, who surprised and routed the patriot forces at Cancha Rayada. But with a reorganized force San Martín met and crushed the royalists at Maipú, April 5, 1818. This victory made good the declaration of independence which had been formally proclaimed on the first anniversary of Chacabuco.

During the next 15 years Chile passed through a period of political uncertainty that fortunately was less prolonged and less anarchic than her neighbours experienced. For five years O'Higgins maintained a fairly efficient personal rule, slightly modified by constitutional offerings of his own devising. After his abdication in 1823 there followed a more unsteady dictatorship under Ramón Freire, which was modified in 1826 by an ill advised attempt at federalism and two years later by the liberal but unworkable constitution of 1828. During this period the Spaniards were finally expelled from Chiloé and that island and the contiguous area incorporated with the country. Aided by a naval contingent under Lord Cochrane (earl of Dundonald) the Chileans united with other patriotic forces in freeing Peru and thus assuring their own security. Then followed recognition by Brazil, Mexico, the United States, and Great Britain. Through the last named country Chile was enabled to float its first external loan.

In domestic affairs the country was less fortunate. A few social reforms, initiated by O'Higgins and Freire, did little to remove the discontent engendered by years of warfare, to counteract the hostility of the Church, or to straighten out financial tangles. Politics

PRIMITIVE METHOD OF MAKING ROPE FROM HEMP FIBRE IN CHILE

was almost wholly personal and merely served to reveal political incapacity. Matters reached a crisis in 1829 with the outbreak of civil strife between Freire, who seemed the only hope of liberalism, and Joaquín Prieto, a successful military chief whom the reactionaries accepted. The conflict was decided at Lircay, April 17, 1830, with the utter defeat of the Liberal forces.

This victory made Prieto president of Chile, but his chief minister, Diego Portales, became its controlling spirit. This conservative leader, the Alexander Hamilton of Chile, aimed at something more substantial than mere military control. He wished to establish the credit of the country and assure its orderly progress. He proposed to continue in power those aristocratic elements that had softened the rigours of colonial control and had kept the struggle for independence clear of unproductive radicalism. With the aid of the *Pelucones* ("Bigwigs"), he centred administration in a President of almost dictatorial powers, whose acts were subject to limited revision by Congress. It was this combination of aristocratic supervision with autocratic administration that constituted the main feature of the Constitution of 1833.

The Autocratic Republic (1831–61).—The government under the new constitution soon faced a series of intrigues that in 1835 called Portales from retirement, and forced the re-election of Prieto. In furthering his efforts to preserve the constitution and to develop the resources of the country Portales now systemized the revenues, reorganized the treasury and refunded the public debt. But the benefits of this policy were measurably neutralized by his severity. Further dissatisfaction was aroused by a conflict with the Peru-Bolivian confederation, in the midst of which a regiment stationed near Valparaiso revolted and seized and assassinated the dictatorial minister, June 6, 1837. His death, regarded as a national calamity, served to fix his policy upon the country more firmly than ever. The war that he had brought about ended with the overthrow of the confederation at Yungay (Jan. 20, 1839). This victory assured the predominance of Chile on the west coast and made its successful general, Manuel Bulnes, the next president.

The first half of Bulnes's double term (1841–51) was an era of conciliation, of material progress, and of cultural awakening. The public debt was liquidated and the customs better regulated. Steamship lines were established, coal mines were opened, and the output of copper and silver was greatly increased. Colonies of Germans were located in the south and in 1849 the Strait of Magellan occupied. This last move provoked a series of boundary disputes with Argentina which were further complicated by similar controversies with Bolivia. Per contra Spain now recognized the independence of Chile, and Peru settled the debt—a legacy of the period of independence—that had helped provoke war between them.

Intellectual expression kept pace with material progress. The National Institute improved its course of instruction. In 1843 the University of Chile opened its doors under the direction of Andrés Bello, a naturalized Venezuelan who later codified the civil law of Chile and attempted to nationalize its language. The Argentine refugee, Domingo F. Sarmiento, headed the first Normal School (1842) and for several years served on the editorial staff of *El Mercurio*. Literary expression manifested itself especially in the press, where José Victorino Lastarria represented reviving liberalism, and Francisco Bilbao, more definitely the revolutionary philosophy of 1848. Growing demands for religious toleration led the State to legalize the marriage of dissenters and to exercise some control over clerical appointments.

After two decades of effective rule the Conservative Party found its supremacy threatened when in 1850 it brought Manuel Montt forward as the successor of Bulnes. But the administration ruthlessly suppressed opposition, which culminated in an unsuccessful revolt, and ushered in the decennium (1851–61) which closed the "autocratic republic." Montt was a fit executive for the period. A pedantic devotion to law and order motivated his policy but once assured of these essentials he devoted himself to developing his country's resources. He introduced the telegraph, began the construction of railways, started the hall of congress and various public buildings, and encouraged the founding of savings banks, the Mortgage Loan Bank, and other financial institutions. Agriculture was aided by the suppression of tithes and of the *mayorazgos*, by the subdivision of rural properties, and by modifying the *alcabalas*. He provided for better primary instruction, for more normal schools, and for public libraries. The discovery of gold in California created for a few years a better market for Chilean flour, but later led to a disastrous financial reaction.

Montt's insistence upon the authority of the State provoked a controversy over the appointment of the archbishop of Santiago and split his party. In a quarrel over the budget the malcontents

were joined by a new party—the Radical—and the combined opposition forced the president to reconstruct his cabinet. This incident was later interpreted as a step toward fixing its responsibility to Congress. When opposition in 1859 became open revolt, Montt with the aid of his efficient co-labourer, Antonio Varas, rigorously suppressed it. It was felt inadvisable, however, to force the election of the latter as his successor.

The Liberal Republic (1861–91).—Joaquín Pérez was a compromise president. He began his administration in a spirit of conciliation and supported by a fusion of Liberals and Conservatives carried it on for ten years without recourse to the "extraordinary faculties," which preceding presidents occasionally used. The opposition maintained by the "Montt-Varistas" (Nationalists) and by the Radicals, mollified by religious and civil concessions, finally secured a constitutional amendment against the re-election of the president. The Radicals also sponsored closer relations with their west coast neighbours, when in 1866 Chile was drawn into the war between Peru and Spain, of which the outstanding event was the wanton bombardment of Valparaiso by the Spanish fleet. The growth in public revenues, which were doubling each decade, permitted this administration to complete the railway between Valparaiso and the capital and to increase expenditures for such public services as the police, the postoffice, and highways. A new commercial code went into effect in 1867 and two years later was held the first National Exposition of Agriculture—both marks of a healthy expansion in production. Colonization was extended into the south at the expense of the Araucanians.

Federico Errázuriz Zañartu (1871–76) continued the record of Pérez for efficient public service. He pushed forward the construction of railways, improved the water front at Valparaiso and finished the edifices for congress, for the University, and for the Agricultural Exposition. At the same time his colleague, Benjamin Vicuña Mackenna transformed and beautified Santiago. The opening of new silver mines and the exploitation of guano deposits and of nitrate greatly stimulated business activity. But still more significant were the political changes of the period. Such issues as the secularization of cemeteries, civil marriage, the separation of Church and State brought the Conservatives forward as champions of ecclesiastical privilege, with the Radicals, aided by a press that was practically free, as their chief opponents. Fundamental changes in the penal code and in the organic Law of Tribunals subjected clerics to civil procedure, restricted the "extraordinary faculties" of the president, and rendered those holding judicial appointments ineligible for other political offices. Amendments to the constitution enlarged the powers of the chamber of deputies, provided for the election of its members by cumulative voting, and made the ministry more thoroughly subject to congress.

His successor, Aníbal Pinto (1876–81) suspended specie payments to meet the economic crisis caused by the exportation of gold and silver, and in 1881 finally settled the long-standing dispute with Argentina over the Strait of Magellan. The quarrel with Bolivia over the guano deposits at Atacama proved insoluble. An attempt had been made in 1866 to settle it by dividing the revenues of the disputed territory. The discovery of silver mines at Caracoles and of nitrate deposits near Antofagasta increased the tension and ultimately led to the War of the Pacific.

Hostilities began in 1879 with the occupation of Antofagasta by Chilean troops. Bolivia immediately declared war and appealed to Peru for aid under the terms of an alliance made in 1873. Chile rejected Peru's offer of mediation and declared war against both republics. The first stages of the conflict were marked by naval engagements at Iquique and at Angamos, Oct. 8, 1879. The latter victory gave Chile command of the sea. After brilliant campaigns the Chileans speedily occupied the province of Tarapacá and followed this with the capture of Arica. Here in Oct. 1880, the contestants met in conference under the auspices of the United States but failed to come to terms. Chile, determined to force a territorial indemnity, then transferred her arms to the vicinity of Lima and in Jan. 1881, after desperate fighting occupied the city. Then followed two years of desultory guerrilla warfare, after which the Peruvians brought together a government that in 1883 accepted the Treaty of Ancón. Under this pact Peru unconditionally ceded Tarapacá to Chile and gave that country control for ten years over Tacna and Arica. At the end of that period, according to the third article of the treaty, a plebiscite should determine whether the provinces were to continue under Chile or return to Peru, the country winning the plebiscite being then obligated to pay the other 10,000,000 pesos. In 1884 Chile and Bolivia agreed to a truce by which the latter yielded to Chile for an indefinite period the province of Antofagasta—its only outlet to the sea.

In the midst of hostilities Domingo Santa María succeeded to the presidency. While bringing the war to a close he also subdued the Araucanian Indians. These successes in the north and south increased the territory of the republic by a third. Within the five years of Santa María's administration (1881–86) the public revenues more than doubled and continued to increase. The government, therefore, was able to meet all existing obligations, to encourage immigration and aid agriculture and mining—in short, to do everything except redeem its paper money. The peso depreciated to about half its value; prices rose accordingly. Thus in a period of apparent national prosperity the masses of the people suffered greatly.

More significant than fiscal issues was the election of an archbishop in Santiago—an act which revived the fervid discussion of "theological reforms." The authorities secularized the cemeteries and recognized civil marriage by law, but failed to bring about the separation of Church and State. At the same time congress extended individual guarantees, assumed the power to override the president's veto by a two-thirds vote, curtailed the powers of local officials, and established manhood suffrage. Yet the president, as before, intervened in the following election and despite prolonged opposition, secured the choice of his designated successor, José Manuel Balmaceda (1886–91).

The new president was a reformer who showed a tendency to use autocratic methods. Yet at the outset he attempted to reconcile his enemies and even permitted them to name the archbishop. Substantial increases in the revenue, especially from the export tax on nitrates, enabled him to initiate a veritable "dissipation of progress," including commendable attention to educational affairs. The system of secondary and higher education had been revised under the law of 1879. Medical instruction was now improved and a pedagogical institute founded for the training of secondary teachers. In fiscal affairs a more just system of taxation was introduced, a tribunal of accounts created, and part of the public debt paid. But the Government made no attempt to abandon the system of paper money. It supplied the army and navy with better equipment and made efforts to encourage immigration.

These improvements were accompanied by complaints of wastefulness and of unnecessary increases in the civil service. At this period also occurred extensive strikes among the labourers, due in part to the depreciation of the currency and to the introduction of workmen from abroad. These conditions gave rise to a new party—the Democrats. The old parties were thoroughly disorganized and at outs with the executive, despite his conciliatory attitude. Cabinets were formed and dissolved mechanically. The president used his influence to elect new members to congress, only to have them join the opposition. The real issue at stake was the election of 1891, which Balmaceda, as usual, planned to dominate in favour of a friend. Congress attempted to checkmate the scheme by adjourning in 1890, without voting supplies. Balmaceda thereupon selected a group of advisers headed by his favoured candidate and announced that he would collect taxes for 1891 under the budget of the preceding year. This step was clearly illegal, but the president's worst offence was his open challenge to the aristocratic and clerical influences that had hitherto dominated the country.

His opponents, who comprised a majority of both houses of congress, did not hesitate to declare themselves in revolt. Led by the vice president of the senate and the president of the chamber of deputies and supported by the navy under Capt. Jorge Montt, they fled northward and established themselves at Iquique. Utiliz-

ing the revenues of the nitrate fields, they recruited an army from the labourers and prepared to fight the dictatorial president. He in turn declared Montt and his levies traitors and raised a force of 40,000 men to combat them. He filled up Congress with his supporters and directed an election in June, when his friend Claudio Vicuña was chosen to succeed him. He aroused further vindictive feeling by the execution in August of several youths belonging to leading families of the country.

Meanwhile his enemies in the north sought to purchase a supply of arms in the United States. Their vessel, the "Itata," evaded the American authorities, but after reaching Chile was forced to return without landing its cargo. The revolutionists finally obtained arms from Europe with which they met and defeated the Balmacedists at Concón and then utterly overwhelmed them at Placilla. Their victory was largely due to the scattering of the president's forces, to treachery in his ranks, and especially to the resentment inspired by his recent arbitrary course. Balmaceda abdicated on the evening of his defeat, took refuge in the Argentine legation and there, on the evening of Sept. 18, the last day of his administration, committed suicide. The contest had cost 10,000 lives and had added materially to the public debt, but it apparently decided that Congress and not the president should control the country.

The Democratic Republic (1891–1924).—The triumphant Congressionalists speedily restored order and in November elected their leader, Admiral Jorge Montt as president. The new president proved a straight-forward, conciliatory official. He and his associates extended amnesty to the greater part of their opponents and assumed the debts contracted by both factions in the late contest. Then they proceeded to consolidate the pretentious parliamentary régime for which they had contended. The Municipal Law of 1892 by which the victors hoped to provide more definitely for local participation in affairs and to forestall further executive interference in elections, was accompanied by a new law of parliamentary incompatibility, which prevented any one drawing a salary from the State from holding a legislative office and definitely shifted the control of elections from the executive to Congress. Political campaigns were henceforth carried on by party groups, seven or more in number, whose leaders resided in the capital and directed the activities of their representatives in each of the communes into which the country was divided.

These party groups now became mere personal followings, which could determine action only through precarious combinations. In presidential elections, however, the parties generally formed themselves into two general groups—the Alliance and the Coalition—of which the former embraced the more liberal elements Yet there was nothing fixed in these combinations. In 1896 the Coalition carried the election of Federico Errázuriz, son of the former president, by a very narrow majority; in 1901 the vote went the other way in favour of Germán Riesco and swung back again five years later.

At this election in 1906 certain groups that were disgusted with sterile political combinations united to form a "National Union." They proposed to bring about "administrative regeneration" in the government and fittingly chose as their candidate, Pedro Montt, son of the man whose earlier administration still suggested law and stability. Although Montt had been defeated in 1901 the "National Union" now put him into office by an overwhelming majority. But the new executive was unable to bring about the redemption of the currency and only after the greatest efforts was he authorized to start construction on the Longitudinal railway. On the completion of the Transandine railway in 1910 President Montt, accompanied by a brilliant entourage, journeyed to Buenos Aires, where the presidents of Argentina and Chile celebrated together the common struggle for independence. In the midst of preparations for the return celebration in Santiago, the president fell ill and in August died while on his way to Europe. Montt's successor also died in September, and Emiliano Figueroa, head of the cabinet, presided over the centennial festivities, and directed the election for president, which took place a few days later. After a prolonged contest within their party the Liberals placed in nomination Ramón Barros Luco, a veteran publicist, whom the Conservatives accepted and who was elected without opposition; but this result did not insure administrative stability nor repress the growing influence of money. Cabinet changes occurred as frequently as before.

Bribery, despite severe laws against it, replaced executive intervention as the controlling factor in all elections, and made procedure therein a matter of purchase and of fraud.

In respect to international affairs the quarter century that followed the Civil War presents a more flattering record. The resentment aroused against the United States over the "Itata affair" led to the still more irritating "Baltimore incident," which was finally settled by Chile's offer of compensation. The Alsop claim, growing out of the war with Bolivia, was finally arbitrated in 1911 by King George V. With the turn of the century there was a recurrence of border quarrels with Argentina, in two regions—the Puna de Atacama in the north and the Patagonian area in the south.

The former was settled in 1899 by arbitration of the U.S. minister in Buenos Aires, but without appeasing popular agitation in either country. In May 1902 the two countries signed treaties which provided for the arbitration of disputes between them, for naval equality during five years and for limitation of armaments. The last two points made this treaty a pioneer. Moreover each country was to remain neutral with respect to affairs upon the other's coast. Some months later the British king, who had been asked to arbitrate the dispute in Patagonia, announced his award, which proved to be a virtual division of the contested area. Thus was ended a controversy that had lasted more than a half century (1847–1902).

In commemoration of this settlement the two nations later joined in erecting on their common boundary above the tunnel of the Transandine railway the famus statue known as the "Christ of the Andes."

In 1904 Chile signed with Bolivia the pact of Santiago by which the former gained full sovereignty in the Atacama region. A secret article of the treaty assured Bolivia an outlet through Tacna-Arica. As a temporary substitute for this corridor Chile agreed to construct a railway from Arica to La Paz (which was completed in 1915) and in 1928 to turn over to Bolivia the portion in the latter's territory. Meanwhile Bolivian goods were given free entry and shipment in bond at Arica. These arrangements created a better sentiment between the two peoples. Chile and Peru, however, could not agree upon terms for holding the plebiscite under the treaty of Ancón. All attempts to arbitrate the question failed. Chile began, after 1908, to interpret the disputed clause as a disguised cession and in 1913 the two countries agreed to postpone for 20 years any further attempts to carry out its provisions.

Through Chile's understanding with Brazil and Argentina and through the participation of the three in the controversies between the United States and Mexico, the country gained marked prestige in Pan American affairs.

The irredeemable paper money affected adversely the volume of trade, and caused a moratorium during the war scare of 1898. Industry which was checked by the Civil War showed a favourable turn before the end of the century. This process was hastened by the protective policy of the government and by its measures to encourage the colonization of the Magellan area and to develop its wool interests and gold washings. The financial crisis of 1907 gave a set-back to industry, already suffering from the great earthquake of 1906.

These successive disasters, however, affected the country less than had at first been feared.

The rise in the cost of living led to demands for increased salaries and wages—demands that in the case of workmen were not granted without frequent resort to strikes. A series of these in 1905 terrorized Santiago and led to bloodshed. Serious disturbances also marked outbreaks at Iquique in 1907 and later in the coal fields of Lota. A few publicists now began to call attention to the misery and squalor that afflicted the Chilean masses and to the general lack of public sanitation. Agricultural labourers in

times of scarcity showed a tendency to migrate, especially to Argentina. Because of this continued public neglect the population of Chile failed to keep pace with its growth in wealth and productivity.

A better situation obtained in cultural activities. A freer press supplied both books and periodicals to wider circles of readers. Primary instruction, both public and private, received fresh impetus from new normal schools, while the Pedagogic Institute (founded in 1889) exerted a marked effect on secondary education. Progress was shown in the establishment of trade schools and in the betterment of professional instruction. A General Congress of Instruction, held in 1902, and a General Congress of Secondary Instruction held ten years later, greatly stimulated the production of didactic treatises and the development of a professional spirit. A reputable group of scientific writers and of historians, of litterateurs and of artists registered the intellectual and social advance of the country and with these cultured and zealous Church officials kept pace.

In the presidential election of 1915 Chile was hampered both by disturbances caused by the World War and by local political strife. In spite of the unanimity that marked the choice of Barros Luco in 1910 and of his general conciliatory policy, partisan spirit showed itself in the intervening elections and forced numerous cabinet changes. Accordingly the Alliance and the Coalition now put forward separate candidates and thus precipitated an exciting campaign in which neither received an actual majority. Congress, with whom final decision rested, chose Juan Luis Sanfuentes, the candidate of the Coalition, who succeeded in reorganizing public administration, in improving the army and navy, in extending railroads, encouraging the commercial marine, constructing port works and public buildings, and beginning the National Library. These improvements were effected despite the grave financial and industrial depression that rested upon the country during the early months of the war, and despite cabinet changes and the later renewal of difficulties with Peru.

Chile had already experienced some trouble in maintaining neutrality when Sanfuentes became president. The country was terribly affected by the loss of European markets. Prussian methods in the army and German scholars among her educators, not to mention a thrifty German population in southern Chile and extensive German business connections, inclined large sections of the people to favour the Central Powers. In 1915 the German cruiser "Dresden" was sunk by a British squadron while supposedly interned in Chilean waters. England apologized for the affront and owing to the clever management of Agustin Edwards, the Chilean minister in London, suffered no further trouble from the incident. Gradually as the war continued public opinion in Chile veered toward the Allies, but the Government maintained its neutrality and continued therein after the United States entered the struggle. Nor did the country fail to reap material rewards from the increase in its trade which in 1916 surpassed that of any previous year and two years later had still further doubled in amount.

The difficulties of the war period were surpassed by those that followed the Armistice. Anti-Peruvian riots at Iquique and Antofagasta in 1918 caused the withdrawal of consular agents from both countries. In the following year Bolivia and Peru, encouraged by the attitude of President Wilson, talked of carrying their grievances to Versailles or to Geneva. By 1920 Peru and Chile were on the verge of hostilities. A *coup d'état* in Bolivia, where Chile was supposed to be exercising too much influence, relieved the situation, and left affairs in train for a more definite *rapprochement* the following year. In the first assembly of the League of Nations Chile gained an important chairmanship and in 1922, its delegate, Agustín Edwards, presided over the assembly.

Post-war recovery was retarded by the slump in nitrate and the ensuing labour disturbances. In the midst of these difficulties occurred the memorable election of 1920. Arturo Alessandri, the candidate of the Liberal Alliance, had served with distinction in Congress and cabinet. He launched his candidacy in 1918 and based his platform on an extensive social program. This precipitate act, typical of the man, increased his prestige as a candidate. As representative of the middle classes and the labour groups, he covered the country in a veritable whirlwind campaign. At the election on June 25, 1920, it was announced that he had received 179 electoral votes to 175 for his opponent. Numerous charges of fraud, however, cast doubt upon the result. The canvass of the voters rested with congress, where each chamber favoured a different candidate. There was a demand for a special court of honour to determine the dispute. In the face of popular clamour, which culminated in a general strike, congress appointed the court and on the basis of its decision gave Alessandri 177 valid votes against 176. The settling of the election by this method, probably saved the country from a revolutionary outbreak.

In his message of June 1, 1921, President Alessandri outlined a program of political and social reform. He wished to improve the conditions of labour and the status of women; to decentralize administration, separate Church and State, change the parliamentary system, establish executive responsibility, and elect the president and vice president by popular vote. A split in the ranks of the Alliance (following a general election to the chamber of deputies) added to the strength of the Conservative groups. In despair at his failure to overcome political opposition and faced with adverse economic conditions Alessandri tendered his resignation Nov. 17, 1921, but was persuaded to continue in office. Some slight betterment in the nitrate industry eased labour conditions, while the adoption of a protocol for the arbitration of the Tacna-Arica dispute diverted attention from domestic difficulties. The Fifth Pan American Congress, which was held at Santiago in April and May, 1923, served momentarily to distract attention from pressing local problems; but fiscal and business affairs showed an alarming uncertainty that was further increased by continued manifestations of unrest among students and labourers. Parliamentary government in Chile seemed hopeless.

Reform and Readjustment.—At the beginning of 1924 affairs in Chile were in an alarming state of uncertainty. Unsuccessful attempts were made to modify by general party agreement the ineffective parliamentary system, to hold a fair election for members of congress, and to carry out the presidential program of reform. With the failure of these efforts, Alessandri determined at all cost to secure control of the reactionary senate. He personally took part in the campaign that preceded the March election and as a result of his intervention, coupled with an extensive but as it proved unnecessary use of military pressure, he carried both houses of congress and for the first time seemed in a position to control public policy.

Congress, however, failed to follow his urgings. The opponents of the administration plotted its overthrow. Unmindful of its increasing unpopularity congress, late in August, intensified the general unrest by proposing to pay its members. Thus it brought upon itself charges of gross selfishness as well as of general incapacity. Army officers attended the sessions of the senate in token of disapproval and in reply to a demand for their punishment forced, on Sept. 5, the installation of a military junta to direct affairs. The president at first agreed to accept its supervision in return for support of his program but soon resigned and left the country. The junta, presided over by General Luis Altamirano, dissolved congress with evident public approval, proposed some fiscal measures, and issued a few "decree-laws" in the way of reform. Then its members seemed to fall under reactionary influences. In Feb. 1925, a second *coup d'état*, directed by the younger army officers, dismissed Gen. Altamirano and his colleagues and recalled Alessandri. A young cavalry officer, Major Carlos Ibáñez, took a conspicuous part in this overturn.

The recalled president received a delirious ovation. He had come back on condition that he be permitted to carry out his program for political and social reform. His way was smoothed by an agreement between the Conservative and Radical parties for the separation of Church and State. The decision in the Tacna-Arica controversy, shortly handed down by President Coolidge, also promised to strengthen his cause. His first care was to prepare a new constitution. This task, after some consideration of a convention, was turned over to a general committee—hand

picked, indeed, but fairly representing all shades of public opinion. A smaller committee, of which Alessandri was chairman, actually prepared the document, which was then submitted to popular vote along with an alternative proposal for a modified "parliamentary" system. The new pact, based on what may be termed "presidential" principles was overwhelmingly successful, although some political groups abstained from voting.

The selection of the new executive caused further difficulty. An attempt to present a single candidate failed. Then Colonel Ibáñez, who had been promoted and was then serving as minister of war, announced his candidacy, thereby disrupting the cabinet and forcing the president's resignation. In alarm at the prospect of military domination most of the political factions came to a belated agreement upon Señor Emiliano Figueroa as a joint candidate. He triumphed at the polls although the leader put forward at the last moment by the more radical elements received a large vote in the capital and industrial centres. In Santiago a general strike followed the election but the acting president, Señor Barros Borgoño, handled the situation firmly, and in Dec. 1925, turned the administration over to president-elect Figueroa.

Each shifting authority of this tumultuous year furthered measures to rehabilitate finances. Unable to secure domestic agreement as to methods, the government finally invited Professor E. W. Kemmerer, of Princeton university, and a group of associates, to study the situation. A decree-law of Sept. 1925, finally embodied the results of their investigation. This act thoroughly revised the fiscal system and created a national bank for the triple purpose of administering the finances of the government, of reducing general rates of interest, and of regulating the other banks of the country. Other decree-laws provided for extensive social legislation, including the regulation of labour conditions and of public health. With the promise of greater stability under the new constitution, Chile seemed destined to experience an important social and industrial advance.

The new administration failed to meet expectations. For some months, indeed, President Figueroa held together a meritorious cabinet, but the legislative factions could not keep from tinkering with executive affairs The Tacna-Arica plebiscite did not materialize and this failure rested heavily on the administration. Many features of the social program were premature and still others proved unpopular. No serious friction occurred over the separation of Church and State, because under agreement, the Government was to continue its ecclesiastical subsidies for five years longer. The national revenues failed to respond to the strain resting upon them.

Changes in 1926 in the ministry of foreign affairs and in that of finance failed to restore public confidence. The one point of stability in the midst of general uncertainty was the ministry of war, still directed by Colonel Ibáñez. A general disruption in the cabinet, late in the year, made the colonel its head, without depriving him, however, of his military control. This new position enabled him to establish a veritable dictatorship, under which Conservatives, Communists, Radicals, Liberals and Democrats were alike proscribed. By such measures he dominated congress and essayed to reform the judiciary, even proceeding to arrest, and finally to banish, the presiding judge of the supreme court, who was President Figueroa's brother.

Before this extreme measure was carried out the president himself quitted office. The executive duties thereby devolved upon Colonel Ibáñez, who continued more openly but not less effectively his policy of administrative reform. In July 1927 an election was held which confirmed Ibáñez as President with virtually dictatorial powers. His administration rested upon a combination of military force and public largess. For a time, through borrowings abroad, he was able to bestow unexampled prosperity on the country. When in 1929 this source of income failed, the true test of his power occurred. In May 1930, came the first proposal to reduce the budget, but it was not accepted. A succession of ministers essayed the hopeless task of reducing expenditures, but when the foreign credit ceased and the efforts to float the nitrate industry likewise failed, the Ibáñez administration of military repression came to an end in July 1931.

Juan Estéban Montero, a liberal law professor, took over temporary rule and, despite his protest, was formally elected president. He inherited a huge deficit from the preceding administration, and faced such additional problems as unemployment, partial crop failure, and an abrupt drop in the revenues. When he proved unequal to the task for which he had been elected, a military revolution, fomented in the aviation school early in June 1932, placed Carlos Dávila in power. After a few days of kaleidoscopic political changes, he essayed a socialistic régime which in September came to an end through a second military revolution. Quarrels between military leaders led the president of the Supreme Court to assume temporary civilian rule. He in turn was followed by Arturo Alessandri, former president of radical tendencies, who now seemed the only hope of the Liberal-Conservative elements. Chosen as chief executive in October, he assumed office in December, with a promise to restore the badly shattered political and economic reputation of the country.

This promise he carried out with reasonable success during the next six years. He rigidly suppressed sporadic attempts at insurrection. Fiscal affairs were entrusted to Gustavo Ross as minister of finance. Within two years the latter had balanced the budget, reorganized Cosach by making it a general sales corporation, and was using the nitrate industry for international trade on a quota basis. By manipulating a portion of the proceeds from this industry, he arranged for token payments on the interest of the foreign debt and sought to redeem the bonds at a fraction of their face value. This arrangement was accepted by Great Britain, but rejected by American, French, and Belgian creditors. In his five years of incumbency, however, Ross did much to restore Chile to a pay-as-you-go basis.

The general economic situation gradually forced the country into a strongly nationalistic policy. Unable to accept adequate imports, the country turned to domestic production. The renewal of gold washings, further issues of paper money, better crops and better prices in time relieved unemployment. Foreign trade increased; public works, especially in the capital and larger cities, helped to meet economic needs. In the midst of continued depression elsewhere, Chile developed a more adequate system of social and economic procedure. The Government encouraged a system of sanitation and public health that easily gave it leadership in Latin America.

The year 1936 marked the 400th anniversary of Diego de Almagro's discovery of Chile. It likewise reopened an era of political strife. Alessandri had attempted to administer affairs with a cabinet representing all the more conservative elements. The Radical Party which had supported him in 1932 found itself divided into rightist and leftist factions. The leftist bloc in Congress attempted to force the ministers of interior and of defence to resign in Feb. 1936, but only succeeded in obstructing the president's legislative program and in precipitating a general strike of railroad employees. This enabled the president to crush the opposition by suspending Congress, declaring martial law and arresting some 600 members of the opposition. When normal procedure was resumed, the president found himself confronted by a Popular Front, from which he tried to detach the Radicals by an offer of three cabinet posts, but they refused unless other leftist parties were also given recognition. This refusal, coupled with frays between Socialist and Nazi groups, with demands for the resignation of the minister of finance, led Alessandri later in the year to ask for dictatorial powers on the pretext of suppressing Communism. This enabled him to gain the congressional election of 1937 by a small majority. The Republican militia, a volunteer force of 50,000 that had supported the Alessandri government for four years, was formally dissolved in July 1936, but reappeared in October as Acción Nacional, definitely pledged to oppose both Communism and Naziism. To meet the demands of radical elements, the Government suggested laws calling for a living wage to workmen, low cost dwelling projects, public works, and adult education. A surplus from 1935 and 1936 enabled the Government to make payments on the foreign debt. Resources mounted, but not so fast as public expenditures or the living cost.

The congressional election of 1937 was but the preliminary

skirmish to the presidential election of 1938. The Radicals, holding the key to the situation, attempted to hold seats in the rightist cabinet and at the same time adhere to the leftist program. Minister Ross resigned his cabinet post in order to force them out of the ministry and to prepare for his own campaign as the Conservative candidate.

Alessandri perforce had to carry on with a cabinet wholly rightist, made up of Conservatives, Liberals and Democrats. As a precautionary measure, the government, on April 10, 1937, banned Nazi mass meetings or parades. Ex-President Ibáñez returned from exile and after some uncertain manoeuvres, became the candidate of the Nacista group. The leftists at first were inclined to support Col. Marmaduke Grove, a socialistic leader in the tempestuous days of 1932, but after bringing the middle-class Radicals into the Popular Front, accepted Pedro Aguirre Cerda, a capitalist and educational leader of moderate social views, as their candidate.

The election of 1938 was marked by bitter discussion, accompanied by resort to violence. Ross was charged with using his position as president of the Nitrate Sales corporation to close the plants and scatter the labourers so as to keep them from voting. A scene of disorder, marked by the wild pistol shot of a Nazi member, greeted President Alessandri when in May he delivered his last annual message before both houses of congress. The arrest and punishment of this member further alienated the leftist groups. Weeks later some young Nazis attempted to seize buildings near the presidential palace, but were quickly subdued with considerable loss of life. Their leader, Deputy J. González von Marées, received a 20-yr. prison sentence. (W. H. Hs.; I. J. C.)

Ibáñez was also arrested, but he was released just before the election and left Chile. Aguirre Cerda was elected by a margin of 4,111 out of 443,525 votes cast and was inaugurated on Dec. 24. The president's first official act was to pardon González von Marées, presumably for the support that the Nacista had thrown to the Popular Front ticket late in the campaign. Ibáñez returned to Santiago Dec. 31 and was welcomed by uniformed Nacista. In Aug. 1939 an unsuccessful coup was led by Gen. Ariosto Herrera and Ibáñez, who had been considered a government adherent.

The government's constructive program was soon seriously interrupted by the disastrous earthquake of Jan. 24, 1939, and by domestic political opposition. The greatest specific achievements were in improved housing.

Chile promptly declared its neutrality in World War II, and participated in the first inter-American foreign ministers' conference at Panamá in September and October 1939.

When President Aguirre Cerda became seriously ill in Nov. 1941, Jerónimo Méndez, little-known president of the Radical party, was named interior minister, and when Aguirre Cerda temporarily withdrew he became acting president. President Aguirre Cerda died Nov. 25, 1941.

In the Feb. 1942 presidential elections, Juan Antonio Ríos, Radical party candidate, won an easy victory; Ibáñez was second.

Ríos' Administration.—Ríos was inaugurated on April 1 for a six-year term. He did not immediately change the policy of neutrality, but congressional debates on it became intense. Socialists were especially active anti-noninterventionists. A great uproar followed the charge made by U.S. Undersecretary of State Sumner Welles on Oct. 8, 1942, that two Latin-American countries (unnamed but interpreted as Chile and Argentina) were used as bases of axis activities. The government began a campaign against axis spies, and broke with the axis powers on Jan. 20, 1943, leaving Argentina as the only American republic maintaining relations. Chile continued, however, to maintain friendly relations with Argentina, and on March 3, 1944, became the first government to recognize the revolutionary Argentine government headed by Gen. Edelmiro Farrell.

Debates in the congress in Feb. 1945 over Chile's war status led President Ríos to assert on Feb. 14 that Chile recognized a state of belligerency with Japan but not with Germany because "that nation is defeated." Ambassador Marcial Mora signed the United Nations pact for Chile at Washington, D.C., on Feb. 14. The senate and the chamber of deputies, on April 5 and 11, respectively, approved a declaration of war, and the president and his cabinet signed it April 11. Ill health forced Ríos to withdraw from active participation in the government on Jan. 17, 1946. In the election of Sept. 4, 1946, Gabriel González Videla won and congress accordingly confirmed his election.

González' government on Oct. 21, 1947, severed diplomatic relations with the Soviet Union, charging inspiration of communist unrest among the coal miners, and on June 22, 1948, a long-fought measure outlawing the Communist party became law.

Return of Ibáñez.—In Oct. 1952 Gen. Carlos Ibáñez del Campo, the former president whose administration had been based on virtually dictatorial powers, was named president by congress, since no candidate in the September election of that year had an absolute majority. Congress in Feb. 1953 voted the president extraordinary economic and administrative powers to facilitate his struggle against inflation and his program for reorganization of the government. Despite these measures, the first half of Ibáñez' six-year term was characterized by excessive ministerial instability and persistently rising inflation, the latter complicated by labour difficulties. Partially because of the narrow majority and the unpredictability of the administration's parliamentary support—the Agrarian Labor party was alone among the major groups backing the president—Ibáñez found it necessary to reorganize his cabinet no fewer than ten times before the end of 1955. On the labour front, martial law was declared in July 1955, when the country was virtually paralyzed by a transport and communication workers' strike. Inflation-inspired demands for wage increases ranging between 60% and 100% touched off a wave of strikes at its peak in August, with about 55,000 workers enforcing stoppages. Branding many of these as illegal, the government imprisoned about 1,000 strikers.

BIBLIOGRAPHY.—The most complete general work is that of Diego Barros Arana, *Historia general de Chile* (16 vols., Santiago, 1884–1902), which covers the period up to 1830 and is virtually continued in his *Un decenio de la historia de Chile, 1841–51*. A convenient summary is to be found in Luis Galdames' *Estudio de la Historia de Chile* (8th ed., Santiago, 1937), (Eng. trans. in 1940 by I. J. Cox, Chapel Hill, N.C.). A. U. Hancock's *History of Chile* is an available English text; but H. C. Evans, Jr., in *Chile and its Relations with the United States* (Durham, N.C., 1927), summarizes clearly the major phases of the country's development during the colonial period, as does I. J. Cox in *Argentina, Brazil and Chile Since Independence*, (Washington, 1935) pp. 279–414.

M. L. Amunátegui contributes for the colonial period the *Descubrimiento y conquista de Chile* (Santiago, 1885) and *Los Precursores de la independencia de Chile* (1870) and numerous other studies. Agustín Edwards' *Peoples of Old*, (London, 1929) deals in popular fashion with the Indians. The standard work on the Indians is Ricardo E. Latcham, *La prehistoria Chilena*, (Santiago, 1928) Abbe Eyzaguirre's *Histoire du Chile* (Lille, 1855) deals with the Church during this period while Horacio Lara's *Cronica de la Araucania* is devoted to the Indians. Crescente Errázuriz, *Historia de Chile* (Santiago, 1911–12) treats of the conquest by Valdivia and the period immediately following. R. B. Cunningham Graham's *Pedro de Valdivia, Conqueror of Chile*, (London, 1926) is a scholarly narrative of the conquest. The monumental editorial works of José Toribio Medina, *Colección de documentos ineditos para la historia de Chile* (Santiago, 1888–1902), his *Cosas de la colonia* (Santiago, 1889), and his *Colección de historiadores i de documentos relativos a la independencia de Chile* (Santiago, 1900–14) form a veritable mine for research on the colonial and revolutionary periods. His *Historia de la Literatura Colonial de Chile*, i-iii (Santiago, 1878), reviews the cultural history of the period. His *Biblioteca hispano-americana, 1493–1810* (Santiago, 1898–1907) is a detailed bibliography in seven volumes. Alejandro Fuenzalida Grandón's *La Evolucion Social de Chile* is an important contribution to colonial social life, as is his *Lastarria i su Tiempo, (1817–1888)*, (Santiago, 1911), to that of the 19th century. Ramón Briseño, *Memoria historico-critica del derecho publico chileno* (Santiago, 1849) is still the standard work on the early constitutions of Chile.

A. Chisholm, *The Independence of Chile*, reviews the struggle against Spain. John J. Mehegan, *O'Higgins of Chile*, (London, 1913), popularizes the life of that hero. A. Edwards' *Bosquejo historico de los partidos politicos chilenos* (Santiago, 1936) and his *La fronda aristocratica* (Santiago, 1928) review the struggle and subsequent national events. His *El Gobierno de Don Manuel Montt, 1851–1861*, (Santiago, 1932), gives the best treatment of that administration. L. Galdames presents a detailed study of certain phases of the period in *La evolución constitucional de Chile*, vol. i. (Santiago, 1926), and José Guillermo Guerra's *Constitucion de 1925* (Santiago, 1929) affords the best commentary on the present Constitution. The *Historia general de la republica de Chile* (Santiago, 1866–82) by B. Vicuña Mackenna and collaborators still has an important place for the revolutionary period. The same author's *Vida de O'Higgins* (Santiago, 1882) and his *Don Diego Portales* (Valparaiso, 1863) are useful supplemental works. Thomas Cochrane, Earl of Dundonald, *Narrative of Services, etc.* (London, 1859) treats of events during the War of Independence from the viewpoint of the outsider.

R. Sotomayor Valdés, *Historia de Chile, 1831–71* (Santiago, 1875) covers less than a decade of the period indicated. P. P. Figueroa, *Historia de la revolucion constituyente, 1857–59* (Santiago, 1895); F. Fonck, *Chile in der Gegenwart* (Berlin, 1870); Sir T. Holdich, *Countries of the King's Award* (London, 1904); I. Errázuriz, *Historia de*

la administración Errázuriz (Santiago, 188?); Joaquim Nabuco, *Balmaceda* (Santiago, 1914); Barros Arana, *La Guerra del Pacifico* (Santiago, 188?), F. Velasco, *Memorias sobre la revolucion de 1891* (Santiago, 1926), C. Walker Martinez, *La Administracion de Santa Maria* (Santiago, 1888–89), are works devoted to individuals and men of importance in the national period. W. J. Dennis in *Tacna and Arica* (New Haven, 1931), summarizes the nitrate war of 1879. Ricardo Salas Edwards, *Balmaceda y el parlamentarismo en Chile* (Santiago, 1925) is the latest review of that epoch. A. Roldán, *El desarrollo constitucional de Chile* (Santiago, 1925) is the best text for the legal background. Alberto Cabero, *Chile y los Chilenos* (Santiago, 1926), combines social, political, industrial features of Chilean life. A Coester in *Literary History of Spanish America* (2nd ed., New York, 1928) has an interesting chapter on Chile. G. F. Scott Elliot, *Chile* (London, 1907) and L. E. Elliot, (New York, 1922) and Fred H Carlson, *Geography of Latin-America*, ch. v. (New York, 1936) are suggestive descriptive works. Occasional articles in *Revista Chilena de historia y geografia* (Santiago, 1911 *et seq.*) and in *Chile* (New York, 1926–31) have historical notes. Carlos Keller R., *Sinopsis Geográfico-Estadistica de la Republica de Chile* (Santiago, 1933) presents a summary of all public activities. *See* also G. J. Butland, *Chile: an Outline of Its Geography, Economics and Politics*, rev. ed. (London, New York, 1953); P. T. Ellsworth, *Chile, an Economy in Transition* (New York, 1945); L. J. Hughlett (ed.), *Industrialization in Latin America* (New York, 1946; London, 1947); J. R. Stevenson, *The Chilean Popular Front* (Philadelphia, London, 1942); G. Wythe, *Industry in Latin America* (New York, 1945; London, 1946).

CHILEAN CIVIL WAR (1891). The Chilean civil war grew out of political dissensions between the president of Chile, J. M. Balmaceda, and his congress (*see* CHILE: *History*), and began in Jan. 1891. On the 6th, at Valparaiso, the political leaders of the Congressional Party went on board the ironclad "Blanco Encalada," and Capt. Jorge Montt of that vessel hoisted a broad pennant as commodore of the Congressional fleet. Preparations had long been made for the naval *pronunciamiento*, and in the end but few vessels of the Chilean navy adhered to the cause of the "dictator" Balmaceda. But amongst these were two new and fast torpedo gunboats, "Almirante Condell" and "Almirante Lynch," as in European dockyards (incomplete) lay the most powerful vessel of the navy, the "Arturo Prat" and two fast cruisers. If these were secured by the Balmacedists the naval supremacy of the congress would be seriously challenged. The rank and file of the army remained faithful to the executive, and thus in the early part of the war the "Gobernistas," speaking broadly, possessed an army without a fleet, the congress a fleet without an army. Balmaceda hoped to create a navy; the congress took steps to recruit an army by taking its sympathizers on board the fleet. The first shot was fired, on Jan. 16, by the "Blanco" at the Valparaiso batteries, and landing parties from the warships engaged small parties of Government troops at various places during January and February. The dictator's principal forces were stationed in and about Iquique, Coquimbo, Valparaiso, Santiago and Concepción. The troops at Iquique and Coquimbo were necessarily isolated from the rest and from each other, and military operations began, as in the campaign of 1879 in this quarter, with a naval descent upon Pisagua followed by an advance inland to Dolores. The Congressional forces failed at first to make good their footing (Jan. 16–23), but, though defeated in two or three actions, they brought off many recruits and a quantity of munitions of war. On the 26th they retook Pisagua, and on Feb. 15, the Balmacedist commander, Eulogio Robles, who offered battle in the expectation of receiving reinforcements from Tacna, was completely defeated on the old battle-field of San Francisco. Robles fell back along the railway, called up troops from Iquique, and beat the invaders at Haura on the 17th, but Iquique in the meanwhile fell to the Congressional fleet on the 16th. The Pisagua line of operations was at once abandoned, and the military forces of the congress were moved by sea to Iquique, whence, under the command of Col. Estanislao Del Canto, they started inland. The battle of Pozo Almonte, fought on March 7, was desperately contested, but Del Canto was superior in number, and Robles was himself killed and his army dispersed. After this the other Balmacedist troops in the north gave up the struggle. Some were driven into Peru, others into Bolivia, and one column made a laborious retreat from Calama to Santiago, in the course of which it twice crossed the main chain of the Andes.

The Congressional *Junta de Gobierno* now established in Iquique prosecuted the war vigorously, and by the end of April the whole country, from the Peruvian border to the outposts of the Balmacedists at Coquimbo and La Serena, was in the hands of the "rebels." The *Junta* now began the formation of a properly organized army for the next campaign, which, it was believed universally on both sides, would be directed against Coquimbo. But in a few months the arrival of the new ships from Europe would reopen the struggle for command of the sea. The Congressional Party could no longer aim at a methodical conquest of successive provinces, but was compelled to attempt to crush the dictator at a blow. Where this blow was to fall was not decided up to the last moment, but the instrument which was to deliver it was prepared with all the care possible under the circumstances. Del Canto was made commander-in-chief, and an ex-Prussian officer, Emil Körner, chief of staff. Balmaceda could only wait upon events, but he prepared his forces as best he was able, and his *torpederas* constantly harried the Congressional navy. By the end of July Del Canto and Körner had done their work as well as time permitted, and early in August the troops prepared to embark, not for Coquimbo, but for Valparaiso itself.

The expedition by sea was admirably managed, and Quinteros, north of Valparaiso and not many miles out of range of its batteries was occupied on Aug. 20, 1891. Balmaceda was surprised, but acted promptly. The first battle was fought on the Aconcagua at Concón on the 21st. The eager infantry of the Congressional army forced the passage of the river and stormed the heights held by the Gobernistas. The killed and wounded of the Balmacedists numbered 1,600, and nearly all the prisoners, about 1,500 men, enrolled themselves in the rebel army, which thus more than made good its loss of 1,000 killed and wounded. The victors pressed on towards Valparaiso, but were soon brought up by the strong fortified position of the Balmacedist Gen. Barbosa at Viña del Mar, whither Balmaceda hurried up all available troops from Valparaiso and Santiago, and even from Concepción. Del Canto and Körner now resolved on a daring step. Supplies of all kinds were brought up from Quinteros to the front, and on Aug. 24, the army abandoned its line of communications and marched inland. The flank march was conducted with great skill, little opposition was encountered, and the rebels finally appeared to the south-east of Valparaiso. Here, on the 28th, took place the decisive battle of La Placilla. The splendid fighting qualities of the Congressional troops and the superior generalship of their leaders prevailed in the end over every obstacle. The Government army was practically annihilated. Valparaiso was occupied the same evening and Santiago soon afterwards. There was no further fighting, for so great was the effect of the battles of Concón and La Placilla that even the Coquimbo troops surrendered without firing a shot.

CHILE-PERUVIAN WAR (1879–82). The proximate cause of this war was the seizure, by the authorities of Bolivia, of the effects of the Chilean Nitrate Company at Antofagasta, then part of the Bolivian Province of Atacama. The first act of hostility was the despatch of 500 soldiers to protect Chilean interests at Antofagasta. This force, under Col. Sotomayor, landed and marched inland; the only resistance encountered was at Calama on the river Loa, where a handful of newly raised militia was routed (March 23, 1879). About the same time Chilean warships occupied Cobija and Tocopilla, and Sotomayor, after his victory at Calama, marched to the latter port. Bolivia had declared war on March 1, but Peru not till April 5: this delay gave the Chileans time to occupy every port on the Bolivian coast. Thus the Chilean admiral was able to proceed at once to the blockade of the southern ports of Peru, and in particular Iquique,

where there took place the first naval action of the war. On May 21, the Chilean sloop "Esmeralda" and the gunboat "Covadonga"—both small and weak ships—engaged the Peruvian heavy ironclads "Huascar" and "Independencia." After a hot fight the "Huascar" sank the "Esmeralda," but Carlos Condell in the "Covadonga" manoeuvred the "Independencia" aground and shelled her into a complete wreck. The Chileans now gave up the blockade and concentrated all their efforts on the destruction of the "Huascar," while the allies organized a field army in the neighbourhood of Tacna and a large Chilean force assembled at Antofagasta.

On Oct. 8, 1879, the "Huascar" was brought to action off Angamos by the "Blanco Encalada," and the "Almirante Cochrane." Although hopelessly outmatched the "Huascar" made a brave fight. When she finally surrendered she had but one gun left in action, her fourth commander and three-quarters of her crew were killed and wounded, and the steering-gear had been shot away. The Peruvian navy had now ceased to exist. The Chileans resumed the blockade, and more active operations were soon undertaken. The whole force of the allies was about 20,000 men, scattered along the seaboard of Peru. The Chileans on the other hand had a striking force of 16,000 men in the neighbourhood of Antofagasta, and of this nearly half was embarked for Pisagua on Oct. 26. The expeditionary force landed, in the face of considerable opposition, on Nov. 2, and captured Pisagua. From Pisagua the Peruvians and Bolivians fell back along the railway to their reinforcements, and when some 10,000 men had been collected they moved forward to attack the Chilean position of San Francisco near Dolores station (Nov. 19). In the end the Chileans were victorious, but their only material gain was the possession of Iquique and the retreat of the allies, who fell back inland towards Tarapacá. The tardy pursuit of the Chileans ended in the battle of Tarapacá on the 27th, in which more men were killed than were wounded, the Chileans suffering a complete defeat. For some inexplicable reason the allies made no use of their victory, continued to retreat and left the Chileans in complete possession of the Tarapacá region. With this the campaign of 1879 ended. Chile had taken possession of the Bolivian seaboard and of the Peruvian province of Tarapacá, and had destroyed the hostile navy.

The objective of the Chileans in the second campaign was the Province of Tacna and the field force of the allies at Tacna and Arica. The invasion was again carried out by sea, and 12,000 Chileans were landed at Pacocha (Ylo), far to the north of Arica. Careful preparations were made for a desert march, and on March 12, 1880, the advanced corps started inland for Moquegua, which was occupied on the 20th. Near Moquegua the Peruvians, some 2,000 strong, took up an unusually strong position in the defile of Cuesta de los Angeles. But the great numerical superiority of the assailants enabled them to turn the flanks and press the front of the Peruvian position, and after a severe struggle the defence collapsed (March 22). In April the army began its advance southward from Moquegua to Tacna. Arica was also watched, and the blockade was extended north of Lima. The land campaign had in the meanwhile culminated in the battle of Tacna (May 26), in which the Chileans attacked at first in several disconnected bodies, and suffered severely until all their forces came on the field. Then a combined advance carried all before it. The allies engaged under Gen. Narciso Campero, the new president of Bolivia, lost nearly 3,000 men, and the Chileans, commanded by Manuel Baquedano, lost 2,000 out of 8,500 on the field. The defeated army was completely dissolved, and it only remained for the Chileans to march on Arica from the land side. The navy co-operated with its long-range guns, on June 7 a general assault was made, and before nightfall the whole of the defences were in the hands of the Chileans. Their second campaign had given them entire possession of another strip of Peru (from Pisagua to Ylo), and they had shown themselves greatly superior, both in courage and leadership, to their opponents.

The Chilean army was reorganized during the summer, and prepared for its next operation, this time against Lima itself. Gen. Baquedano was in command. The leading troops disembarked at Pisco on Nov. 18, 1880, and the whole army was ready to move against the defences of Lima six weeks later. These defences consisted of two distinct positions, Chorrillos and Miraflores, the latter being about 4,000 yd. outside Lima. The first line of defence was attacked by Baquedano on Jan. 13, 1881. The defenders had 22,000 men in the lines, the Chileans engaged about 24,000. The battle of Chorrillos ended in the complete defeat of the Peruvians, less than a quarter of whose army rallied behind the Miraflores defences. Two days later took place the battle of Miraflores. Here the defences were very strong and the action began with a daring counter-attack by some Peruvians. Neither party had intended to fight a battle, for negotiations were in progress, but the action quickly became general. Its result was, as before, the complete dissolution of the defending army. Lima, incapable of defence, was occupied by the invaders on the 17th, and on the 18th Callao surrendered. The resistance of the Peruvians was so far broken that Chile left only a small army of occupation to deal with the remnants of their army. The last engagement took place at Caxacamara in Sept. 1882, when the Peruvians won an unimportant success.

CHILI or CHILE, the pods of several kinds of peppers, notably the capsicum, used as a condiment. A dish of meat and beans, called chili con carne, highly flavoured with chili, is popular in the United States; it is generally, though erroneously, believed to have originated in Mexico. In tropical countries chilies are used in many ways to flavour foods.

CHILIA (KILIYA), a town formerly in Bessarabia, Rum., in the department of Ismail, on the Chilia branch of the Danube. Pop. (1930) 17,049. Anciently known as Chilia, Chele or Lycostomium, it was a place of banishment for Byzantine political dignitaries in the 12th–13th centuries, a Genoese trading settlement 1381–1403, then Walachian, Moldavian and Hungarian. It was taken by Turkey in 1484, by Russia in 1812 and by Rumania in 1918. Ceded with Bessarabia to the U.S.S.R. in June 1940, it was regained by Rumania during the axis attack on the U.S.S.R. in 1941. In 1947 it was returned to the Izmail oblast, Ukrainian S.S.R. The official name is Kiliya.

CHILIASM, the belief that Christ will return to reign for a thousand years (from Gr. χιλιασμός, χίλιοι, a thousand), the doctrine of the Millennium (*q.v.*).

CHILLÁN, a city and the capital of the province of Ñuble, in the southern part of central Chile, 246 mi. by rail south-southwest of Santiago and about 56 mi. direct (108 by rail) northeast of Concepción. Pop. (1952) 52,576. Chillán is one of the most active commercial cities of central Chile, and is surrounded by a rich agricultural and grazing country. Chillán was founded by Ruíz de Gamboa in 1580. Its present site was chosen in 1836. The original site, known as Chillán Viejo, was the birthplace of the liberator, Bernardo O'Higgins. Chillán was severely damaged by an earthquake in 1939. The hot sulphur springs of Chillán, known since 1660, are about 45 mi. east-southeast. They issue from the flanks of the Volcán Viejo, about 7,000 ft. above sea level. The highest temperature of the water issuing from these springs is a little over 135°. The principal volcanoes of the Chillán group are the Nevado (9,528 ft.) and the Viejo. After a two-century repose, Nevado de Chillán erupted violently in 1861 and 1864 and slightly in later years.

CHILL HARDENING, the process of hardening the surface of a metal by rapidly cooling it while it is molten or at a very high temperature. Usually the chilling is done by plunging the object in a bath of water or oil. In the case of railway and other wagon and car wheels, a "chill mould" is used, consisting of a sand mould with the outer part (which forms the rim) made of cast iron. When the wheel is cast, the rim cools very rapidly because the iron part of the mould absorbs and conducts away the

heat from it, and the consequent chilling hardens the rim. Chill hardening is sometimes combined with case hardening. (*See* FOUNDING; CASE HARDENING; IRON AND STEEL.)

CHILLIANWALLA, a village of British India in the Punjab, situated on the left bank of the river Jhelum, about 85 mi. N.W. of Lahore. It is memorable as the scene of a battle on Jan. 13, 1849, between a British force commanded by Lord Gough and the Sikh army under Sher Singh. The loss of the Sikhs was estimated at 4,000, while that of the British in killed and wounded amounted to 2,800, of whom nearly 1,000 were Europeans and 89 were British and 43 native officers. An obelisk erected at Chillianwalla by the British government preserves the names of those who fell. (*See* SIKH WARS.)

CHILLICOTHE, a city of northern Missouri, U.S., on the Grand river, 80 mi. N.E. of Kansas City; the county seat of Livingston county. It is on federal highways 36 and 65 and is served by the Burlington, the Chicago, Milwaukee, St. Paul and Pacific, and the Wabash railways and by bus lines; it has a municipal airport. Pop. (1950) 8,649. Coal and limestone abound in the vicinity, and much livestock is raised. The city has various manufacturing industries, and is one of the principal assembling points for dairy products in the state. The state industrial school for girls and a business college are there.

Chillicothe was settled about 1830. The town was laid out in 1837 on land granted by the federal government, and the city was incorporated in 1855. A famous tavern of the '50s, kept by "Uncle Johnny" Graves, is now a beautiful private residence. A tablet on the county courthouse commemorates the death, in 1868, of Nelson Kneass, composer of the music for "Ben Bolt," who drifted there with a travelling theatrical troupe.

CHILLICOTHE, a city of Ohio, U.S., on the Scioto river, 50 mi. S. of Columbus; the county seat of Ross county. It is on federal highways 23, 35 and 50, and is served by the Baltimore and Ohio and the Norfolk and Western railways. Pop. (1950) 20,121. It is the trade centre of a rich agricultural region. The city has railway repair shops, paper mills, a shoe manufacturing industry and an aluminum fabricating industry. There are ancient mounds (Mound City Group National monument) 4 mi. north. Chillicothe was founded in 1796. On the Camp Sherman site of 1914–18 are a veterans' hospital and a federal reformatory. Chillicothe was the capital of the Northwest territory in 1800–03, and the capital of Ohio in 1803–10 and 1812–16.

CHILLINGWORTH, WILLIAM (1602–1644), English divine, was born at Oxford in Oct. 1602. He was persuaded by a Jesuit to embrace Catholicism and went to study at the Jesuit college at Douai. After a short stay, however, he left Douai in 1631 and returned to Oxford. On grounds of Scripture and reason he at length declared for Protestantism but declined a preferment offered to him in 1635. His principal work was *The Religion of Protestants a Safe Way to Salvation* (1637).

CHILLIWACK, an incorporated city of British Columbia, Can., on the Fraser river, 70 mi. E. of Vancouver. Pop. (1951) 5,663. It is on the trans-Canada highway, is served by the Canadian National railways and is connected by ferry with Harrison Mills on the Canadian Pacific line. Sawmilling and timber manufactures, canning, mineral water and dairy produce works are of importance. The fertile district east and west of the city, incorporated as the municipality of Chilliwack (pop., 1951, 13,677), is devoted chiefly to hop culture, dairy farming and small fruit growing, and has been extended by the drainage of Sumas lake (30,000 ac.).

CHILOÉ, a province of southern Chile, and also the name of a large island off the Chilean coast forming part of the province. The province (area 9,052 sq.mi., pop., 1951, 95,893) is composed of numerous islands and a section of the mainland which border on the gulfs of Ancud and Corcovado. The mainland portion of the province is extremely rugged and is virtually uninhabited, such colonies, towns and Indian settlements as there are being principally on the island of Chiloé. The island, which is some 90 mi. long by 35 mi. wide, lies within the temperate rainforest belt of South Chile, where frosts are rare, summers are cool, and rainfall is abundant throughout the year. Both the coast range of western Chiloé and the rolling plains of the east are heavily forested with large evergreens (mostly broad-leaved) such as *alerce, roble, ciprés,* cinnamon trees and filberts. For four centuries these dense forests, which are too wet to be burned, have provided an effective barrier to the majority of white settlers who have tried to clear the land for cultivation and pasturage. Logging operations have never been developed on an extensive commercial scale, and most of the timber that is cut is consumed locally. Ancud, the capital of the province (pop. 4,327 in 1940), is situated at the N. end of the island on the sheltered bay of San Carlos. Castro, the oldest and only other sizable town in the province (pop. 4,786 in 1940), is on the eastern shore of the island, 55 mi. S.E. of Ancud by rail.

CHILON, of Sparta, son of Damagetus, one of the Seven Sages of Greece, flourished about the beginning of the 6th century B.C. In 560 (or 556) he acted as ephor, an office which he is even said to have founded. According to Chilon, the great virtue of man was prudence, or well-grounded judgment as to future events.

A collection of the sayings attributed to him will be found in F. W. Mullach, *Fragmenta Philosophorum Graecorum,* i; *see* Herodotus, i, 69; Diogenes Laertius i, 68; Pausanias iii, 16, x, 24.

CHILPERIC, the name of two Merovingian Frankish kings.

CHILPERIC I (d. 584) was one of the sons of Clotaire I. On his father's death in 561, fearing that, as he was illegitimate, his brothers would deprive him of his share of the patrimony, he seized the royal treasure at Berny and entered Paris, prepared to bargain. The resulting division of the patrimony gave Chilperic the old Salian territories of the modern Picardy, Flanders and Hainaut; this included Soissons. When Charibert died in 567, Chilperic's share of his property included lands and cities in the west and in Aquitaine. Distrust of his brothers, fear for his insecure eastern frontier and the perpetual need of land and treasure for his followers caused Chilperic to attack Sigebert's town of Reims. There followed a series of campaigns in which Reims and Soissons were the key points. Sigebert's marriage to the Visigothic princess Brunhilda (Brunechildis), daughter of King Athanagild, seemed to endanger Chilperic's possessions in Aquitaine; so Chilperic put away his wife and married Galswintha, Athanagild's elder daughter. This prudent step angered his followers, who hated the Arian Visigoths. Galswintha was shortly murdered, to be replaced by Chilperic's former mistress, Fredegond (*q.v.*). This lady was Gregory of Tours's pet aversion, but Chilperic's subjects seemed to prefer her to her predecessor. The consequent vendetta with Sigebert and Brunhilda, in which Guntram of Burgundy acted occasionally as arbitrator, lasted, almost without pause, for 40 years and was castigated by Gregory of Tours as *bella civilia.* After Sigebert's murder in 575, Chilperic became effectively master of the *regnum Francorum.* The Visigothic king Leovigild sought the hand of his daughter Rigunthis for his heir Reccared. Chilperic was assassinated near Chelles in 584.

Chilperic was naturally ferocious and appeared to Gregory of Tours as the Nero and the Herod of his time. But he was the ablest and most interesting of the grandsons of Clovis. As a bastard he had to fight for his existence; yet, a builder of circuses, he seems to have had ideas about a king's duties that were Roman or Byzantine rather than Germanic. His fiscal measures were vigorous and provoked the hatred of the church (which suffered from them). His court circle had something more than pretensions to culture; it appreciated poetry and even theological discussion. Chilperic held his own views on the doctrine of the Trinity and revised the Latin alphabet to suit his tastes. It is a pity that our sources allow us to get no nearer to the motives of his wild, unhappy career.

CHILPERIC II (d. 720), son of Childeric II, was already middle-aged when, in 715, he was taken from a monastery to become king of Neustria, his name being changed from Daniel. He appears to have been the tool of Ragenfrid, his mayor of the palace; and after Ragenfrid's defeat by Charles Martel and the Austrasians, Chilperic fell into the hands of Odo of Aquitaine, who, himself defeated, surrendered him to Charles. On the death of Clotaire IV of Austrasia in 719, Chilperic became king over the whole

regnum Francorum. Charters were issued in his name, and from these the abbey of St. Denis was a notable beneficiary.

(J. M. W–H.)

CHILTERN HILLS, a range of chalk hills in England extending from southwest to northeast through parts of Oxfordshire, Buckinghamshire, Hertfordshire and Bedfordshire. Considerable areas are cared for by the National trust. The Chilterns form a well-marked escarpment facing northwestward, with a long south-eastern slope, and run from the Thames in the neighbourhood of Goring to the headwaters of its tributary the Lea between Dunstable and Hitchin, the crest line between these two points being about 55 mi. These hills are part of a larger chalk system, continuing the line of the White Horse hills from Berkshire, and themselves continued eastward by the East Anglian ridge, a series which represents the edge of the chalk rising from beneath the Eocene deposits of the London basin. The greatest elevation in the Chilterns is between Watlington and Tring, where they reach 800–900 ft. Toward the Thames gap to the west the elevation falls away only a little, but eastward the East Anglian ridge seldom exceeds 500 ft. Several passes through the Chilterns are used by roads and railways converging on London. The hills were formerly covered with beech, which is still the characteristic growth and the main raw material of the chair and furniture manufactures of High Wycombe.

CHILTERN HUNDREDS. An old principle of English parliamentary law declared that a member of the house of commons, once duly chosen, could not *resign* his seat. This rule was a relic of the days when the local gentry had to be compelled to serve in parliament. The only method, therefore, of avoiding the rule came to be by accepting an office of profit from the crown, a statute of 1707 enacting that every member accepting an office of profit from the crown should thereby vacate his seat, but should be capable of re-election, unless the office in question had been created since 1705, or had been otherwise declared to disqualify for a seat in parliament. Before this time the only course open to a member desiring to resign was to petition the house for its leave, but except in cases of incurable ill-health, the house always refused it. Among the posts of profit held by members of the house of commons in the first half of the 18th century are to be found the names of several crown stewardships, which apparently were not regarded as places of profit under the crown within the meaning of the act of 1707, for no seats were vacated by appointment to them. The first instance of the acceptance of such a stewardship vacating a seat was in 1740, when the house decided that Sir W. W. Wynn, on inheriting from his father, in virtue of a royal grant, the stewardship of the lordship and manor of Bromfield and Yale, and *ipso facto* vacated his seat. On the passing of the Place act of 1742, the idea of utilizing the appointment to certain crown stewardships (possibly suggested by Sir W. W. Wynn's case) as a pretext for enabling a member to resign his seat was carried into practice. These nominal stewardships were eight in number, but only two survived to be used in this way in contemporary practice—those of the Chilterns and Northstead; and when a member wishes to vacate his seat, he is accordingly spoken of as taking the Chiltern Hundreds. The Chiltern Hundreds formed a bailiwick of the ordinary type. They are situated on the Chiltern hills, Buckinghamshire. The appointment of steward was first used for parliamentary purposes in 1750, the appointment being made by the chancellor of the exchequer (and at his discretion to grant or not), and the warrant bestowing on the holder "all wages, fees, allowances and other privileges and pre-eminences." Up to the 19th century there was a nominal salary of 20s. attached to the post. It was laid down in 1846 by the chancellor of the exchequer that the Chilterns could not be granted to more than one person in the same day, but this rule has not been strictly adhered to, for on four occasions subsequent to 1850 the Chilterns were granted twice on the same day. The Chilterns might be granted to members whether they had taken the oath or not, or during a recess, though in this case a new writ could not be issued until the house met again. Each new warrant expressly revoked the grant to the last holder, the new steward retaining it in his turn until another should be appointed.

See parliamentary paper—*Report from the Select Committee on House of Commons* (*Vacating of Seats*) (1894).

CHILWA (incorrectly SHIRWA), 15° 15′ S., 35° 40′ E.; a shallow lake of brackish water in the Nyasaland Protectorate abutting on Mozambique. Its area varies with the rainfall, but never exceeds 100 sq.mi. Formerly, at a period of higher level, it appears to have drained northward to the Lujenda branch of the Rovuma. There are four islands, one rising 500 ft. above the water level. The lake was discovered by Livingstone in 1859.

CHIMAERA. A term applied botanically to certain types of plants formerly regarded as "graft hybrids." The term graft hybrid suggests a plant produced by the fusion of vegetative cells derived respectively from two plants grafted together. That hybrid plants do in fact originate in such a way is, however, regarded by most botanists as problematical. It is true that plants composite in nature and having some of the characteristics of the two plants employed may result from an operation of grafting, but these are usually interpreted as arising in an entirely different way without the fusion of cells that would justify the appellation of hybrid. The term graft hybrid has been replaced in general by "plant chimaera" or simply "chimaera," since, like the mythological monster so-called, plant chimaeras are composite in nature and origin.

Many of these plants have been long known in gardens, being grown as curiosities rather than for their decorative value. The earliest to be described in scientific literature was the Bizzaria orange which appeared in a garden in Florence in 1644, arising as an adventitious bud from the region where a scion of sour orange (*Citrus aurantium*) had been grafted on a stock of citron (*Citrus medica*). Others are the so-called *Crataego-mespilus* forms, arising in a similar way following the grafting of medlar (*Mespilus germanica*) on hawthorn (*Crataegus monogyna*); the *Pyro-cydonias* from the grafting of pear (*Pyrus communis*) on quince (*Cydonia vulgaris*); and, best known of all, *Cytisus adami* (or *Laburnum adami*) from the grafting of the small purple-flowered broom (*Cytisus purpureus*) on the common laburnum (*Laburnum vulgare*). In all these instances the history of origin is the same; the plants at present in existence have been derived by vegetative propagation from an adventitious shoot that arose at the junction of scion and stock.

While all the examples mentioned above originated as the result of a horticultural operation, their production was unintentional. Knowledge of the subject passed into a new phase with Hans Winkler's experiments in 1907 deliberately designed to produce graft hybrids. In these experiments black nightshade (*Solanum nigrum*) was grafted on tomato (*Solanum lycopersicum*). After the graft had taken, a transverse cut was made through it at the junction of the stems. From the exposed surface numerous buds developed which grew into new shoots, all of which were shoots either of nightshade or of tomato except one; this, arising at the junction of the two tissues, had the characters of nightshade on one side and tomato on the other. Winkler called this shoot a *chimaera*, since it was partly of one species and partly of another. In the following two years large-scale experiments were carried out resulting in the production of many thousands of shoots from decapitated grafts. Most of these were either pure nightshade or pure tomato, some were chimaeras of the kind already described, but in addition there were a few shoots showing characters intermediate between scion and stock. These differed among themselves as to the extent to which they resembled scion or stock and Winkler gave them special names, believing them to be true graft hybrids.

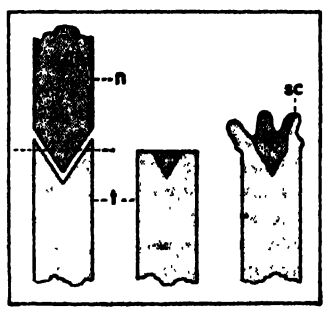

Fig. 1.—Stages in the production of a chimaeral branch; Winkler's method. Dotted line indicates position of cut. n, nightshade; t, tomato; sc, sectorial chimaera

In 1909 Erwin Baur published observations on variegated plants, in particular the garden geranium (*Pelargonium zonale*)

In such plants branches sometimes occur in which one side is green and the other colourless, corresponding structurally to the tomato-nightshade branch to which Winkler first applied the term chimaera. In the present instance the distribution of the two kinds of tissue constituting the branch is dramatically obvious owing to the difference in colour. Such a branch, called by Baur a

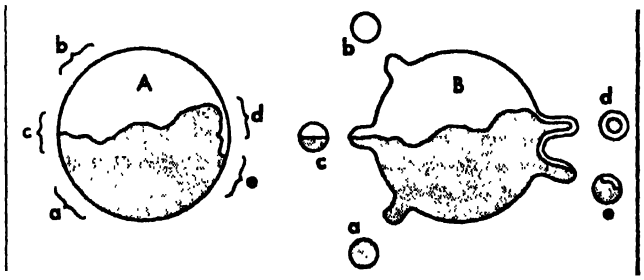

Fig. 2.—A. Diagram of a cross section of the stem of a sectorial chimaera consisting of green and colourless tissue; the line of junction between the two tissues is often very irregular
B Illustrating how there may arise from such a stem pure green (a), pure white (b), sectorial (c), periclinal (d), or mericlinal (e), branches, depending on the position of lateral bud formation

sectorial chimaera, when cut through transversely usually presents an appearance as shown at A in fig. 2. The nature of any lateral shoot arising from it depends on the place of origin; shoots arising at b and d will be pure green and pure white respectively, while one arising at c will possess a sectorial structure like the parent branch. If a shoot arises as at d where, as often occurs, a superficial strip of one component overlaps the other, a *periclinal chimaera* will result—an arrangement in which a "core" of green tissue is invested by a "skin" of colourless tissue, one, two, or more cell layers thick, depending on the thickness of the overlap; or vice versa. If the bud arises at the extreme edge of the overlap the superficial "skin" may occupy only part of the surface of the shoot, a condition described as mericlinal. Thus, a branch having a sectorial structure gives rise during growth, not only to occasional sectorial branches like itself, but to branches that are pure for either component, periclinal, or mericlinal. In contrast to this instability, a branch that has once acquired a periclinal pattern shows very great stability of structure during growth, producing lateral branches that are all periclinal chimaeras like the parent branch.

Baur's experience with these chimaeras of *Pelargonium* composed of green and colourless tissue led him to suggest that Winkler's so-called graft hybrids between nightshade and tomato were in reality periclinal chimaeras, and he provided cogent evidence that two of the plants to which Winkler had given special names were built up of a core of tomato with a skin of nightshade one and two cell layers thick respectively, and two of the others of a core of nightshade with skins of tomato one and two cell layers thick. After some hesitation Winkler fully concurred with Baur's interpretation. (A fifth form obtained by Winkler unfortunately died before it could be fully investigated.)

Attention was then turned to *Cytisus adami* and the other long-known "graft hybrids." The general consensus of opinion in 1944 was that these also are periclinal chimaeras: *Cytisus adami,* for example, consisting of a core of laburnum invested with a one-layered skin of *Cytisus purpureus,* the *Crataego-mespili* having a core of hawthorn covered with skins of medlar differing in thickness in the different forms, and so on.

Owing to the fact that in flowering plants the reproductive cells arise from the layer second from the surface at the growing point, seedlings from periclinal chimaeras are all pure core if the skin is but one cell layer thick, and all pure skin tissue if the skin consists of more than one layer; they are never periclinal chimaeras like the parent plant. Also, while stem branches or stem cuttings reproduce the periclinal condition, root cuttings yield invariably plants of core tissue only owing to the endogenous manner in which lateral roots are formed.

Apart from being an occasional product of grafting, chimaeras also arise in nature, most frequently, no doubt, as the result of a sudden mutation in some cell or cells of a growing region. The new kind of tissue may be conspicuously different from the old as when it is colourless instead of being green, but far more commonly the difference is evident only on special investigation as when the number of chromosomes is altered. Thus, chimaeras are of far greater frequency than the readily recognizable examples met with might suggest. In contrast to the graft-hybrid interpretation which predicates a blending of the two components, the chimaera hypothesis regards the components as maintaining their identity, but arranged in a definite pattern at the growing point; the manner in which vegetative growth occurs in flowering plants is responsible for the way this pattern is transferred from the growing point to the mature tissues. The whole behaviour of these plants in reproduction and vegetative growth, as well as the nature and arrangement of their mature tissues accords well with the supposition that they are chimaeras. The alternative graft-hybrid hypothesis cannot be said to be theoretically impossible, but it may be regarded as improbable in view of what is known of plant behaviour and as lacking positive support from indubitable evidence. Nevertheless it still has its supporters, few though they may be, as exemplified by Trofim Lysenko and his followers, representing one Russian school of thought.

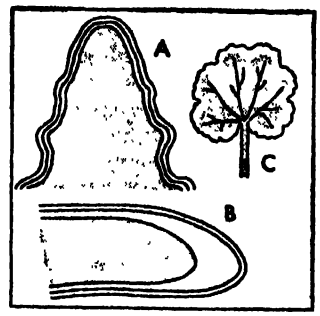

Fig. 3.—A. Longitudinal section through the growing point of a periclinal chimaera in which the cells of the central core possess potentially green plastids while in the two outer cell layers the plastids lack the capacity to become green
B. Transverse section near the edge of a leaf derived from such a growing point. Owing to the whole of the marginal tissue, apart from the epidermis, being derived from the second layer of the growing point, the leaf has a white margin
C. Superficial appearance of a leaf from such a periclinal chimaera. The central part of the leaf, as well as the stem, appears green since the green core tissue shows through the two enveloping layers of colourless cells

While in no sense conclusive, it is at least significant that variegated foliage as described above for *Pelargonium zonale* is commonly met with in flowering plants of all kinds, but never occurs in groups such as the ferns with a single-celled growing point. This is what would be expected if such variegation is correctly interpreted as a consequence of the possession of a growing point having a chimaeral structure, for which a multicellular growing point is a necessity.

BIBLIOGRAPHY.—R. J. Chittenden's article "Vegetative Segregation," *Bibliographia Genetica* (1927); and F. E. Weiss's review in *Biological Reviews* (1930) give detailed accounts in English of many aspects of chimaeras; Krenke's volume, translated from Russian into German under the title *Wundkompensation, Transplantation und Chimaeren bei Pflanzen* (1933) gives a later and more general discussion of the subject. All three are provided with full bibliographies. *Plant Chimaeras and Graft Hybrids,* by W. Neilson-Jones (1934) will be found to provide a general treatment of all aspects of the subject up to that date within a relatively small compass. Later experimental work, which is not extensive, must be sought in scientific journals.

(W. N. J.)

CHIMAERA. In Greek mythology a chimaera was a fire-breathing female monster resembling a lion in the fore part, a goat in the middle, and a dragon behind (*Iliad,* vi, 179). She devastated Caria and Lycia until finally she was slain by Bellerophon (*q.v.*). In art the Chimaera is usually represented as a lion, with a goat's head in the middle of the back, as in the bronze Chimaera of Arezzo (5th century). The word is now used generally to denote a fantastic idea or fiction of the imagination.

Chimaera, or *chimère,* in architecture, is a term loosely used for any grotesque, fantastic or imaginary beast used in decoration.

CHIMAY, a town in the extreme southeast of the province of Hainaut, Belgium, dating from the 7th century. Pop. (1939) 3,250. Owing to its proximity to the French frontier it has undergone many sieges, the last of which was in 1640, when Turenne reduced it to ruins. The town is chiefly famous for the castle and park that bear its name. Originally a stronghold of the Cröy family, it has passed through the D'Arenbergs to its present owners, the princes of Caraman-Chimay. The castle, which in

1640 possessed seven towers, has now only one, which is in ruins; a château was built in the Tudor style in the 18th century. This domain carried with it the right to one of the twelve peerages of Hainaut. The church contains a fine monument of Phillippe de Cröy, chamberlain and comrade in arms of the emperor Charles V. Jean Froissart, the chronicler, is said to have died here, and has a statue in the square.

CHIME. (1) Probably derived from a mistaken separation into two words, *chimbe bell*, of *chymbal* or *chymbel*, the old form of "cymbal," Lat. *cymbalum*. A mechanical arrangement by which a set of bells in a church or other tower, or in a clock, are struck so as to produce a sequence of musical sounds or a tune. (For the mechanism of such an arrangement in a clock and in a set of bells, *see* the articles CLOCKS and BELL.) (2) From Mid. Eng. *chimb*, a word meaning "edge," common in varied forms to Teutonic languages, *cf.* Ger. *Kimme*, the bevelled rim formed by the projecting staves at the ends of a cask.

CHIME-BELLS, a mediaeval instrument consisting of a set of small bells of varying pitch which were arranged in a frame and struck with a hammer after the manner of a glockenspiel. They ranged in number from four or five up to as many as 14 or 15. The chime-bells were known also under the Latin name of *cymbalum*.

CHIMERE, in modern English use the name of a garment worn as part of the ceremonial dress of Anglican bishops. It is a long sleeveless gown of silk or satin, open down the front, gathered in at the back between the shoulders, and with slits for the arms. It is worn over the rochet, and its colour is either black or scarlet (convocation robes). The origin of the chimere has been the subject of much debate; but it is practically proved to be derived from the mediaeval tabard, an upper garment worn in civil life by all classes of people both in England and abroad. It has therefore a common origin with certain academic robes (*see* ROBES: *Academic Costume*). The word "chimere," which first appears in England in the 14th century, is of uncertain origin. It occurs in different forms in various languages (Lat. *chimera*, Fr. *simarre*, Ital. *zimarra*) and may possibly be derived from the Greek χειμέριος, "wintry." This derivation is made plausible by the original character of the chimere; for the word properly applies to the sleeveless tabard which tended to supersede, from the 15th century onwards, the inconvenient *cappa clausa* (a long closed cloak with a slit in front for the arms) as the out-of-doors upper garment of bishops. The chimere was, moreover, a cold weather garment. In summer its place was taken by the tippet. In the Anglican form for the consecration of bishops the newly consecrated prelate, hitherto vested in rochet, is directed to put on "the rest of the episcopal habit," *i.e.* the chimere. The robe has thus become in the Church of England symbolical of the episcopal office, and is in effect a liturgical vestment. The civil quality of the garment still survives; the full dress of an Anglican prelate at civil functions of importance (*e.g.* in parliament, or at court) is still rochet and chimere. The continental equivalent of the chimere is the *zimarra* or *simarre*, which is defined by foreign ecclesiologists as a kind of *soutane* (cassock), from which it is distinguished by having a small cape and short, open arms (*manches-fausses*) reaching to the middle of the upper arm and decorated with buttons. In France and Germany it is fitted more or less to the figure; in Italy it is wider and falls down straight in front. Like the *soutane*, the *zimarra* is not proper to any particular rank of clergy, but for bishops and prelates it is ornamented with red buttons and bindings. It is worn by university professors. A black *zimarra* lined with white, and sometimes ornamented with a white binding and gold tassels, is worn by the pope.

CHIMKENT, a town in the Syr Daria province of the Kazak (Kirghiz) A.S.S.R. of the R.S.F.S.R., Lat. 42° 20′ N., Long. 69° 40′ E. Pop. (1939) 74,185, mostly Sarts. It lies in a fertile valley between the Alexander range and the Ala-tau, and is the centre of a grain, fruit growing and cattle rearing district, watered by streams from the Ala-tau. Above the town are the ruins of its citadel, stormed by the Russians in 1864. Its clear, dry air makes it a health resort for tubercular patients taking the kumiss (fermented mare's milk) cure.

Its industries include the preparation of santonin, cotton, tobacco, oil and flour.

The construction of a branch line from the Orenburg-Tashkent Railway through Chimkent to link up with the Trans-Siberian Railway at Semipalatinak should restore to Chimkent much of its former trading importance.

CHIMNEY, that portion of a building by means of which smoke is conveyed from fires inside to the outside air. The necessity of a chimney appears only when braziers are abandoned in favour of large fireplaces. Thus in northern Europe in the 12th century the primitive hole in the roof yielded to a hollow flue leading from a fireplace by the wall to the outside; but a specific architectural form of flue was not developed until the 15th century. The 13th and 14th century type was a simple, round, vertical conduit of stone, with a conical cap and openings at the sides under the cone. A remarkable example occurs in the monastic kitchen of the Abbey of Fontevrault, France, dating from the end of the 12th century. In the early 15th century the re-duplication of fireplaces led to the grouping of several flues inside a vertical, and generally rectangular, mass of masonry, which was carried well above the roof, and occasionally decorated. In France, in the latter half of the century, this decoration was of great richness, consisting of late Gothic pinnacles and niches, and in the châteaux of the Francis I. period, chimneys vied with dormers in their lavish detail. Heraldic ornaments, pilasters and entablatures abound. In England, decorative effect was obtained by grouping the flue tops as independent features, usually in brick, above a stone base; each flue was then treated as a separate shaft with base and cap, polygonal or twisted; *e.g.*, Compton Wynyates and Hampton Court palace. In the early Renaissance, the flues were sometimes treated like little classic columns, as at Burleigh House. With the development of classicism, the chimney became simple

A FRENCH RENAISSANCE CHIMNEY (FRANCIS I. PERIOD), CHÂTEAU OF BLOIS; B. ENGLISH TUDOR, FROM COVENTRY; C. AMERICAN COLONIAL WARRIER HOUSE, PORTSMOUTH, N.H. (EARLY 18TH CENTURY)

again, a mere rectangular mass of masonry. In colonial work America, the chimney is either a large square mass in the cent of the roof or else developed as an important feature of the e gable walls. In the Italian Renaissance the chimney is mer utilitarian and, whenever possible, is hidden. (T. F. H.)

CHIMNEY AND FIREPLACE CONSTRUCTION

Correct chimney construction is absolutely essential to econo cal home heating. The ideal and most efficient chimney is verti with round flue and smooth interior surfaces (fig. 1). All ch

neys should be built with "fire-clay" flue linings (not "flue-tile," "terra-cotta" or "clay" flue lining). Faulty chimney construction practically always shows its shortcomings by its effect upon some other feature of the plant. A lighted paper thrust in the bottom and sucked up and consumed with a roar is often erroneously taken to indicate a good draught. Chimney draught can be known definitely only by measurement with the proper instrument, a

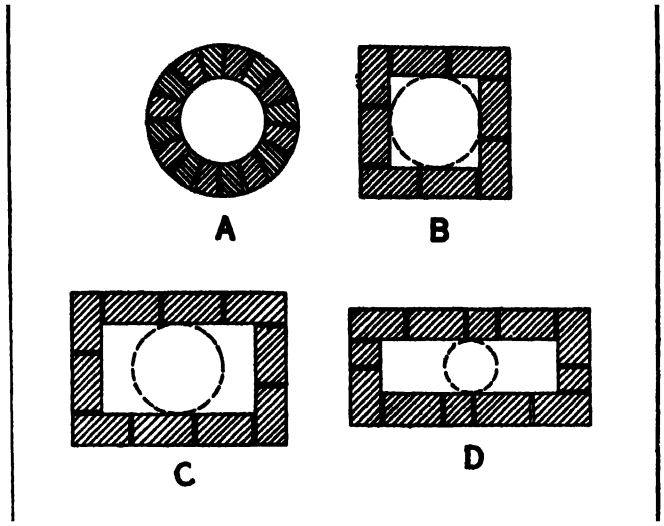

FIG. 1.—EXAMPLES OF CHIMNEY CONSTRUCTION. A. ROUND FLUE; B. SQUARE FLUE; C. OBLONG FLUE; ELONGATED OBLONG FLUE. TYPE A IS THE BEST, TYPE B, SECOND BEST, TYPE C, NEXT PREFERABLE, TYPE D, POOR CONSTRUCTION

draught gage. Chimney height and temperature inside and outside the chimney determine intensity of draught in a correctly built chimney.

Factors that contribute to faulty chimneys are: (1) Insufficient height to assure proper draught and avoid interfering air currents (fig. 2); the top of a chimney should extend at least 3ft. above flat roofs and at least 2ft. above the ridge of peaked roofs; extensions, if used, should be fitted with air-tight joints; (2) omission of flue-lining to ensure continued tightness, so that heat and weathering cause mortar gradually to disintegrate and result in a leaky chimney (fig. 2); (3) offsets and bends are likely to reduce the chimney free area and present difficulties in construction that militate against tightness and inside smoothness; loose bricks and mortar may fall and lodge in such a way as to cause objectionable restricted areas and provide lodgement for dangerous soot accumulations (fig. 2); (4) careless and improper installation of the smoke pipe into the chimney (fig. 3); (5) openings into a chimney for other than the smoke pipe of the boiler; such should never be permitted, they are apt to check and interfere with the draught; (6) lack of a tightly-fitting cover for the clean-out door; (7) failure to support the chimney properly; it should never be based on timber construction and when resting upon the ground sufficient masonry foundation should be provided to prevent settling; (8) improper laying of brick; it should never be laid on edge, should be properly bonded and sufficient mortar used between the bricks to fill all voids. Size and height of chimneys depend upon the total heat demands of the structure to be served, the type and number of boilers and the fuel to be used. Reputable manufacturers specify draught requirements for their respective equipment and state the required flue areas, sizes and heights of chimneys; these should be observed. Irrespective of fuel used, the minimum effective area[1] inside the flue lining for any installation should be not less than 70 sq.in. and the short cross-sectional dimension should be never less than six-tenths of the greater dimension. The minimum chimney height above the grate should be 35ft. if erratic draughts are to be avoided.

A chimney that is not tight will fail to draw properly. Force or direction of wind, the amount of moisture in the air or the quality of the fuel may aggravate the trouble. A smoke test will prove leaks and every flue should be tested before a boiler is connected thereto, by building a paper, straw, wood or tar-paper fire at the base of the flue. When the smoke is passing in dense volume

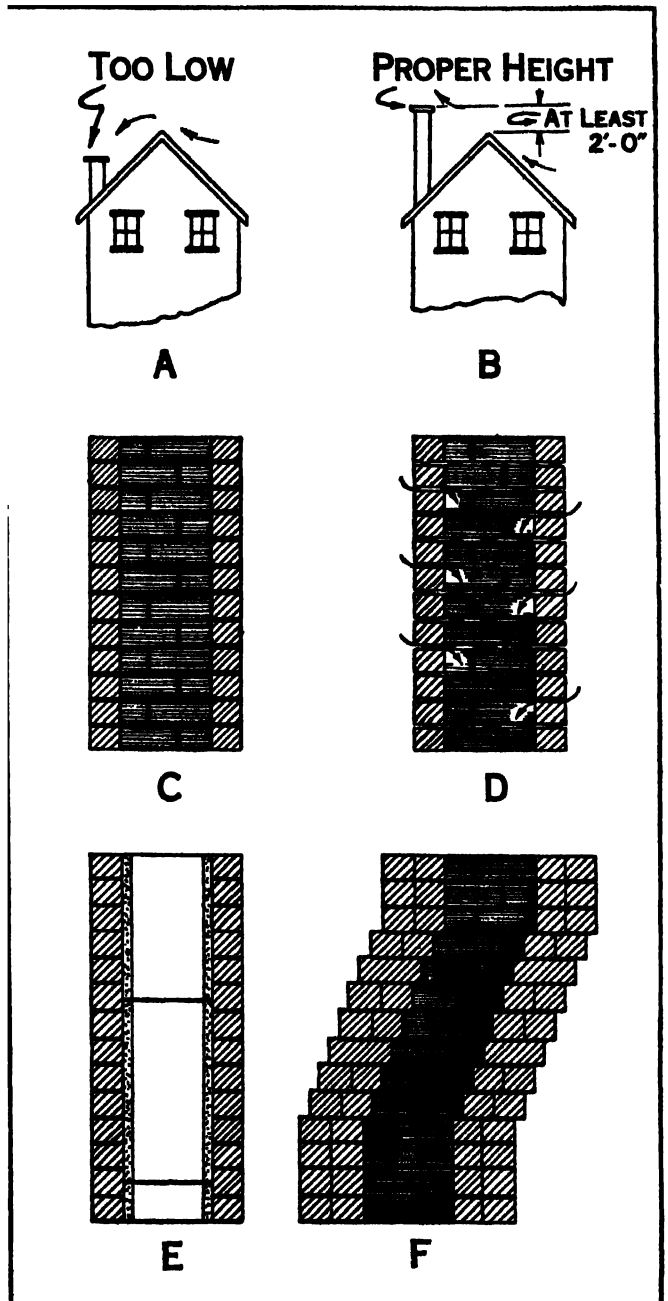

FIG. 2.—EXAMPLES OF CHIMNEY CONSTRUCTION. A. TOP TOO LOW, EDDY CURRENTS CAUSE DOWN DRAFT; B. TOP CARRIED PROPER HEIGHT; C. UNLINED FLUE BEFORE USE; D. UNLINED FLUE, LEAKS CAUSED BY HOT GASES AND WEATHERING; E. LINED FLUE, A PREVENTION AGAINST LEAKS; F. OFFSETS TO BE AVOIDED

if the stack be tightly blocked by laying a wet blanket over it, the leakage will be immediately evident by the appearance of smoke at the opening, or from an adjoining flue indicating leakage between the flue joints.

If a leakage is not obviously evident, further inspection by means of a mirror held at the proper angle at the base of a straight flue should be made for minor obstructions such as broken tile, mortar accumulations, birds' nests, partly burned paper, soot or tarry deposits; or removal may be accomplished by passing up and down the flue a weighted bag of hay or straw attached to the end of two ropes.

[1]Effective area of a flue, broadly speaking, is the theoretical cross-sectional area occupied by the column of smoke and gases rising with spiral motion up the flue.

Fireplaces.—A satisfactory open fireplace requires: (1) a flue of proper area, (2) fireplace throat correctly proportioned and located, (3) a correctly built smoke shelf and chamber, (4) sufficient chimney height, (5) a shape for radiating maximum heat into the room. The area of a lined flue should equal one-tenth or more of that of the fireplace opening. For unlined flues, the proportion should be increased due to greater friction. For lined flue,

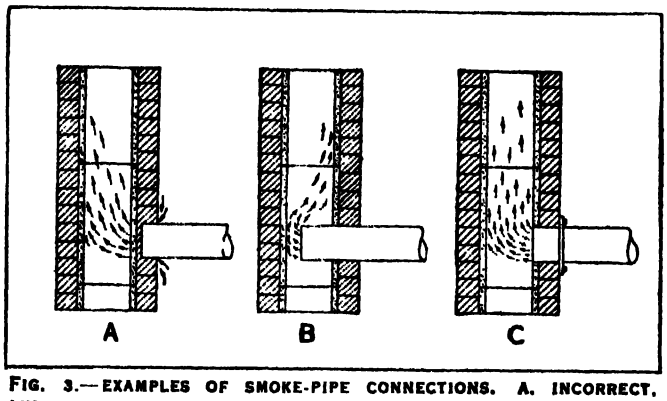

FIG. 3.—EXAMPLES OF SMOKE-PIPE CONNECTIONS. A. INCORRECT, LEAKY JOINT; B. INCORRECT, PIPE PROJECTS TOO FAR INTO CHIMNEY; C. CORRECT, PIPE MEETS EDGE OF FLUE AND JOINT PROPERLY SEALED

allow 13 sq.in. of clear flue area to each square foot of fireplace opening. The cross-sectional area should be the same throughout the entire length of the chimney.

Correct throat construction is essential, to avoid a smoky fireplace and to provide for proper velocity of the outgoing gases. The area of the throat should be not less than that of the flue, its length always equal to the width of the fireplace opening (fig. 4); the sides of the fireplace should be vertical until the throat is passed (fig. 4); and above the throat, the sides should be drawn in until the desired flue area is obtained; the throat should be not more than 4 or 5in. in width and set 8in. above the lintel of the opening (fig. 4). The use of a throat damper is advisable; if omitted, the throat opening should be 4in. and the smoke shelf

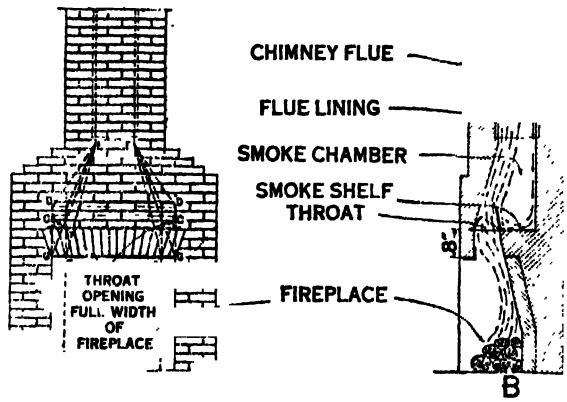

FIG. 4.—FAULTY AND CORRECT FIREPLACE CONSTRUCTION. A. TOP OF THROAT DAMPER IS AT DD, SMOKE SHELF AT CC. SIDE WALL SHOULD NOT BE DRAWN IN UNTIL THE HEIGHT DD IS PASSED. IF DRAWN IN AS INDICATED BY EF AND EG, THE WIDTH OF THROAT BECOMES LESS THAN THE WIDTH OF THE OPENING AND CAUSES THE AIR CURRENTS TO PILE UP RESULTING IN A SMOKY FIREPLACE. B, CORRECT FIREPLACE CONSTRUCTION

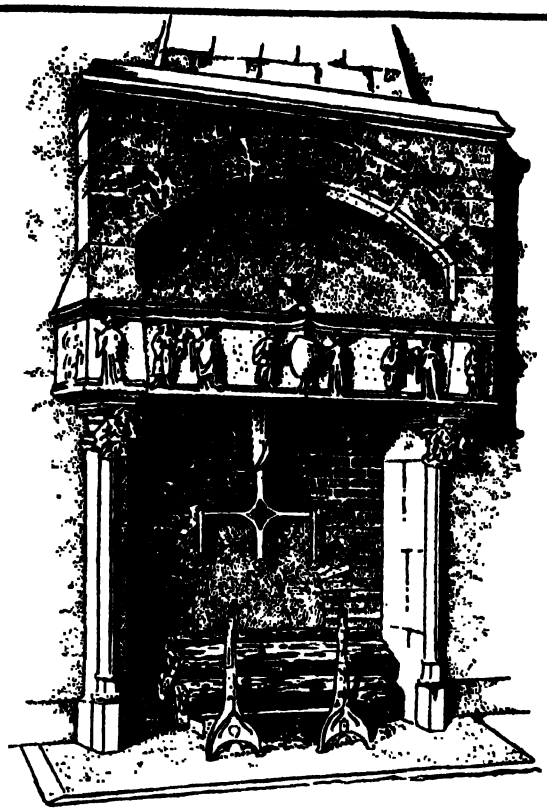
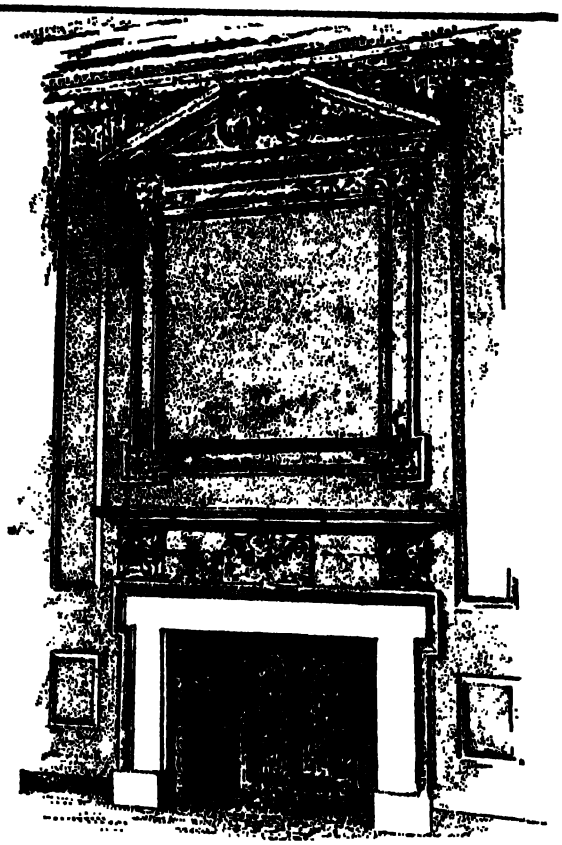
always included. A smoke shelf and chamber are absolutely essential. The shelf is formed by setting back the brick work at the top of the throat to the line of the flue wall, making the shelf equal in length to that of the throat. No shelf should be less than 4in. and may vary from this to 12in. or more, depending on depth of fireplace; the level of the shelf should be 8in. above the fireplace opening (fig. 4). The smoke chamber acts as a reservoir to hold accumulated smoke temporarily when a gust of wind across the chimney top momentarily dampers the chimney, as well as to lessen the down draft and prevent smoke being forced into the room. All smoke chamber walls should be smooth inside. The back of a fireplace should pitch forward from a point a little less than half-way from the hearth to the top of the opening and the sides should be beveled, as straight back and sides do not radiate heat as well.

The use of a throat damper affords means for regulating a fire. The type with lid hinged at rear, rather than in the centre, directs better the outgoing smoke into the flue. Full opening is required for fast-burning pine; slow-burning hardwood logs require only 1 or 2in. openings. Fireplace openings should be kept low, 30in. minimum and 42in. maximum height. The higher the opening, the greater the possibility of a smoky fireplace; the width of opening should be slightly greater than the height; a minimum depth of 18in. is advisable although 12in., in small fireplaces, will provide a good draft with properly constructed throat.



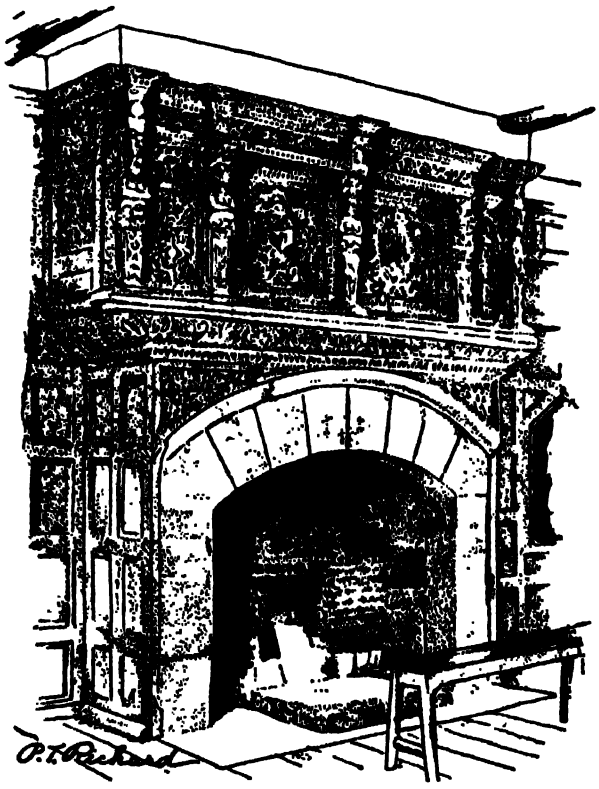
Efficiency of fireplace heating can be improved materially by the use of a fireplace heater which heats all incoming air before it enters the room. These devices consist of an intake air manifold, into which air from the outside is drawn and delivered into heat pipes lining the rear wall of the fireplace, from which it passes into a heated air manifold and is then delivered into the room directly above the fireplace openings at temperatures varying from 135° to 195° F. Tests have shown that the use of a proper fireplace heater is the means of increasing measurably the effectiveness of fireplace heating, through, (1) raising the room temperature 3½ times as quickly as can be done with the bare fireplace, (2) maintaining a far more even temperature throughout the entire room, (3) avoiding cold air leakage through window and door cracks and (4) by producing a greater heating effect with less fuel than when no heater is used. (A. M. D.)

See J. J. Norman, *Design of a Brick Chimney* (1913); J. G Mingle, *Draft and Capacity of Chimneys* (1925); A. Custodis, *Radical Brick Chimneys* (1924).



CHIMNEY-PIECE, in architecture, originally a hood, projecting from the wall over a grate, built to catch the smoke and lead it up to the chimney flue; later, any decorative development of the same type or for the same purpose; a mantel or mantelpiece. Like the chimney (*q.v.*), the chimney-piece is essentially a northern mediaeval development. Its earliest form, a simple hood, sometimes with shafts below, at the wall, is shown in the king's house at Southampton and at Rochester castle, England (12th century). Later, the spaces under the ends of the hood were made solid, so that the fireplace became a rectangular opening, and in some cases the fireplace was recessed into the wall. Late mediaeval fireplaces are of great size and richness, e.g. the triple fireplace in the great hall of the Palais des Comtes at Poitiers, and the earlier fireplaces in the château of Blois.

During the Renaissance fireplace openings were decorated with columns, pilasters and entablatures, and occasionally the front of the wall or hood above the overmantel was enriched. North Italian palaces are full of examples of great delicacy. In France the fireplaces at Blois and Chambord are famous. In England, the same formula appears in naïve and complex types, with the usual Elizabethan and Jacobean *mélange* of misunderstood classic and Flemish motives—strap work, gaines, etc. In France, after a brief classicism under Henry II. and Henry IV., the chimney-piece became a centre of fantastic design. Although the opening was usually small, the decoration was rich, and commonly characterized by the use of a great mirror as an overmantel. The detail assumed the classic extravagance of the Louis XIV. style, the swelling curves and bulbous shells of the Louis XV. and the distinguished restraint of the Louis XVI. styles, but almost always retained the same general proportions and the mirror. German design largely followed that of France; chimney-pieces are less numerous there, however, owing to the use of porcelain stoves.



In England the Renaissance chimney-piece was at first treated with simple architraves, frieze and cornice, in such a way as to serve as mantel shelf, occasionally with rich panelling above and much breaking or keying of the mouldings. Later, consoles caryatides and columns were used, although occasionally a simple moulding of sweeping profile replaced the architrave, and the shelf was omitted. In the last half of the 18th century the char

CHIMNEY-PIECES FROM THE 15TH TO THE 20TH CENTURIES

The early fireplaces of the Gothic period were enormous in order to permit the burning of large logs, but the manner in which they smoked led to a continued decrease in size, which reached a climax in modern English chimney-pieces designed for burning coal. The projection of the chimney breast has always been realized as a decorative opportunity and was developed in nearly all the Renaissance styles

acteristic English chimney pieces, in the style of Robert Adam, owed much to Louis XVI influence. In American colonial work there is an almost exact following of English precedent, and occasional examples can be traced to definite plates in English architectural books.

CHIMPANZEE, the popular name of one of the African anthropoid apes (*Pan troglodytes*), characterized by being smaller than the gorilla (*q.v.*). It has very large, outstanding ears and its abundant hair is black in colour. Frequently the area around the mouth is white. Males are only slightly larger than females; they weigh about 120 lb. and standing erect may be about 4½ ft. in height. The chimpanzee is found from French Guinea to western Uganda and Belgian Congo. A pygmy species (*Pan paniscus*) occurs on the south side of the Congo river, but the various forms farther north, although they show great variation, are probably only races of the common species. The nomenclature of the chimpanzee is greatly complicated, partly because of confusion with the orangutan by early writers. *Anthropopithecus, Troglodytes* and *Simia* are frequently used as generic names, although the last has been ruled invalid for any animal.

Chimpanzees are forest animals living in small family groups—an adult male, one or several females, infants and several partly grown young. It takes 9 to 12 years for them to reach maturity. The territory of such a band is about ten miles square. These apes spend most of their time in the trees, where they construct crude sleeping platforms high above the ground. On the ground chimpanzees walk on all fours, using the knuckles of the hands. The skin shows friction ridges and is horny, like that of the palm. They occasionally stand upright, but rarely walk in this position unless trained. Chimpanzees have a sense of rhythm, shown by a kind of dance, and they drum on trees or the ground, producing a primitive music. Their food includes many fruits, shoots of certain plants, occasionally varied by insects and birds' eggs. They raid cultivated fields of cane, pineapple, cacao or bananas.

The popular interest in this ape lies in its resemblance to man. Physiologically and anatomically it is more like man than like the tailed monkeys. Its intelligence is also manlike, as has been amply shown by experiments and studies by psychologists Wolfgang Köhler, Robert M. Yerkes and others. The lack of capacity for speech seems absolutely to preclude the attainment of a culture or social inheritance. (*See* PRIMATES.)

CHIN, a Burmese term for a hillman applied in particular to branches of the Kuki (*q.v.*) race, inhabiting the hills along the west bank of the Chindwin river south of Manipur.

CHINA, a vast country of eastern Asia, bordering the U.S.S.R. and the Mongolian People's Republic for more than 6,000 mi. on the north and west; it is flanked by Korea on the northeast; the Yellow sea, East China sea and South China sea on the east; Indochina and Burma on the south; and the Karakoram and Himalaya ranges on the southwest. Including Manchuria, Sinkiang and Tibet on the mainland and Formosa (Taiwan) and numerous smaller islands, China has a total area of approximately 3,876,956 sq.mi. with a population of about 475,000,000 (1950 official est.). After the victory of the Chinese Communists and the flight of the Nationalist government to Formosa (Dec. 8, 1949), China was virtually divided into two entities: Communist China on the mainland and the Nationalist government on Formosa.

The Central People's (Communist) government in Peking, which was formally inaugurated in Oct. 1949, was founded on the principles of Marx, Lenin and Stalin and of Mao Tse-tung's New Democracy. (The Chinese Communist party was founded in Peking in 1921.) The Nationalist government in Taipei, Formosa, was based on Sun Yat-sen's Three Principles of the People and the five-power constitutional system. Its official name is Chung-Hua Min-Kuo; *i.e.,* Republic of China.

INTRODUCTION

Agricultural China.—Less than half of China's total area is essentially Chinese. The country's civilization has always rested upon agriculture, and Chinese culture has extended as a dominant institution only into those areas where cultivation is possible. The majority of political China is either too dry, too hilly or too cold for farming; these vast spaces, while relatively empty and hence relatively easily incorporated into the Chinese polity, are inhabited for the most part by non-Chinese people whose cultures and economies are markedly distinct from the human patterns of agricultural China.

"China proper," as this agricultural area is often called, consists of 18 provinces, bounded by the sea to the east, the mountains to the south and west and the desert to the north. The Great Wall, completed, from earlier walls, as a continuous unit by the emperor Ch'in Shih Huang Ti in the 3rd century B.C., still serves to mark a line between farming and grazing along the desert border of agricultural China in the north and northwest. Not all of the area of the 18 provinces is arable, however, and in fact mountains, hills and climate, especially in the west and south, combine to keep almost three quarters of it out of cultivation. In many of the areas—for example, the southwest—the population is still largely non-Chinese. Agriculture also increasingly spread out beyond the limits of China proper after the middle of the 19th century as population pressure mounted. Southern Manchuria and the moister parts of Inner Mongolia have in particular been largely occupied by Chinese farmers. But the 18 provinces of China proper do contain the bulk of the agricultural land, the great majority of the Chinese people and the roots and body of Chinese civilization.

Manchuria was sparsely settled before 1900. Chinese political claims to it were weak but were made effective by the mass immigration of farmers. Southern Manchuria has rich resources of broad, level land, coal, iron, timber and water power, which were largely developed by the Japanese during their period of control from 1931 to 1946. Under Chinese Communist control after 1947, the original three provinces of Heilungkiang, Kirin and Liaoning were redivided into nine administrative units. Manchuria's current distinction from China lies to a considerable degree in the commercialized and industrialized nature of its economy, a reflection of accessible resources and of heavy Japanese and Russian investment in railways and manufacturing between 1890 and 1946.

Mongolia is a vast steppe bordering on the desert of central Asia. The moister southern sections, designated as Inner Mongolia (or the Chinese provinces of Ningsia, Suiyuan, Chahar and Jehol—not part of the 18 provinces), have especially since the end of the 19th century been infiltrated by Chinese farmers and drawn more firmly under Chinese political control. The remaining drier sections, known as Outer Mongolia and sparsely though almost exclusively occupied by Mongols, are oriented to the Soviet Union. Outer Mongolia's independent status as the Mongolian People's Republic was recognized by both the Nationalist and Communist governments of China in agreements with the Soviet Union.

Sinkiang is the westernmost extension of political China, a desert corridor between the two arms of the mountain mass of central Asia, the Tien Shan and Kuen-Lun (Kunlun) ranges. Its earlier name of Eastern or Chinese Turkistan reveals its non-Chinese culture, as well as the reason for the repeated assertion of Chinese control: it is the traditional overland connection with the west. Most of Sinkiang's people belong culturally to the Turkish group, and life centres in the scattered string of oases from east to west along the base of the mountain escarpment. These oases, following both the northern and southern margins of the desert basin, nourished the old silk route from China to Europe and the middle east. At Kashgar and Yarkand passes lead out of the desert basin and across the Pamirs into Russian Turkistan and Afghanistan. Another route westward runs north of the basin through the oases of Hami and Urumchi into the steppe of Dzungaria, which is also included in the province of Sinkiang. Chinese authority in Sinkiang tended to be increasingly nominal after 1900, and Russian influence grew. The Chinese Communist government established its control in Sinkiang in late 1949.

Tibet, like Mongolia, has two parts, though it is less usable from a human point of view. The terms "hither" and "farther" Tibet record this division, the first referring to the borderland areas in the east fronting on agricultural China and low enough or with a series of narrow river valleys to permit farming. About 80% of Tibet's cultivated area and the majority of its population are there. Most of hither Tibet is included in the Chinese provinces of Sikang and Chinghai (or Koko-nor) (not part of the 18 provinces), reflecting not only the penetration of agriculture but the need for a buffer against nomadic raids from farther Tibet. Most of farther Tibet is too high, rugged and cold for agriculture. It is extremely thinly occupied by a non-Chinese population whose support comes largely from nomadism based on the yak, from the raising of barley in a few favoured places, and from the trade routes connecting India, China and central Asia which pass through the country, with their most notable focus at Lhasa, the capital. Chinese sovereignty over all of Tibet has usually accompanied the rise of a strong dynasty in China. As central authority in China weakened during the 19th century the theocratic government at Lhasa became increasingly independent. Though Great Britain and Russia recognized China's suzerainty by treaty in 1907, Tibet remained very loosely attached until the Chinese Communist government carried out a military occupation as far as Lhasa in 1951 and obtained an agreement conferring on Peking all control of foreign affairs, currency and defense.

The interaction between agricultural China and the outer areas of political China is in part a measure of their differences, but equally of the attractive power, wealth and prestige of Chinese civilization. Despite the distinctions outlined above, "greater China" is a living entity, with a degree of unity which belies its regional distinctiveness.

China Proper.—It is neither practicable nor useful to generalize in physical detail about an area as diverse as China. The outer areas, for all their community with China proper, must be treated separately. Even within the 18 provinces, an area which reaches across 20° of latitude and 28° of longitude, there is great physical variation. "China" as used hereinafter refers exclusively to China proper.

THE LAND

Rivers and Their Basins.—Physiographically, China proper is centred on three great river systems, each rising in the high escarpment of the west and running fortunately across the greatest extent of the country from west to east, so that they complement the north-south sea route. Roughly the northern quarter is drained by the Hwang-ho (Yellow river), the middle half by the Yangtze river and the southern quarter by the Si Kiang (West river). Of these the Yangtze is by far the most important, since the varied waterways of its basin (exclusive of the almost myriad canals in the delta area) are navigable by steamships or junks or both for about 20,000 mi. Approximately half of China's people live in the Yangtze basin, and it includes the richer and more productive half of the country. The usefulness of the Yangtze itself is greatly implemented by the fact that it receives a series of navigable tributaries from both north and south, each draining its own productive area. (Alternate north and south tributaries also join with the relatively even moist climate of central China to maintain navigability and to lessen the danger of floods.) These include, in ascending order, the Kan, from the south, with its mouth at Kiukiang; the Han, from the north, with its mouth at Hankow; the Siang, from the south, with its mouth in Tungting lake, draining into the Yangtze; and the Kialing, from the north, with its mouth at Chungking. As a result, much of the trade of both north and south China (as well as nearly all the trade of central China) drains via the Yangtze, which is itself navigable for ocean-going ships as far upstream as Hankow, 630 mi. from the sea.

The Hwang is a typical arid-climate river, running as it does through dry northwest China, north in a great loop into the Ordos desert of Inner Mongolia, and finally down across the semiarid north China plain. It is characterized by a high silt content, by violent seasonal fluctuations in volume and by recurrent and disastrous changes of course. It is thus almost useless for navigation, although small native craft use it along scattered stretches in Honan and between Paotou and Lanchow-fu (Lanchou) farther west. The river's most dramatic effect on the land is its frequent floods, hence the epithet "China's sorrow." Silting of the bed increased as cultivation of the hillsides in the Hwang watershed spread during the historical period; natural and artificial levees along much of the river's lower course have prevented the regular release of silt, and thus the bed lies in many places above the level of the surrounding plain.

The inevitable break-through of pent-up floodwaters may be permanent, in the form of a new course, but even on a smaller scale the destruction and loss of life are great. However, silt deposition from the Hwang and its tributaries over the north China plain has helped to make this the most fertile major agricultural area in China. The Hwang's course has seldom been constant for more than 100 years during the historical period, and changes have taken it both north and south of the Shantung peninsula. The Si Kiang or West river is a lesser stream than the Yangtze or the Hwang, and its watershed is restricted by the high relief characteristic of south China. It is navigable by steam launches for about 250 mi. from its mouth near Canton, but it lacks major navigable tributaries on the scale of the Yangtze, and its basin is far less productive. Nevertheless, as the largest river in south China, which also contains south China's largest lowland area, it is the most obvious core of this extensive region.

Rivers are important in China not only as physiographic classifiers but for two more pragmatic and particular reasons. First, in this largely preindustrial economy and except for the arid north, rivers are the cheapest and almost the only practicable means of transport for many bulk goods moving beyond local markets. Railway development was still in its infancy in the 1950s, largely restricted to a few major trunk routes, and in any case still too expensive to compete effectively with water transport. Second, China, aside from the north, is not on the whole an area of naturally fertile soils, and high relief further limits agriculture. But in the river valleys fertile alluvial soil and level land are available, plus water for irrigation, which is even more important in the north than in the south. As a result of these two sets of factors, China's population is markedly concentrated along its rivers and reaches its highest and most extensive density at their mouths, where the advantages for transport and agriculture are at the maximum. Hence the primacy of Shanghai among China's cities, the prominence of Canton, Hong Kong, Nanking and Hankow, and the deltaic emphasis of settlement in both north and south.

Relief.—China has often been schematically divided between the mountainous south and the more level north, but topographic distinctions are also clear as between east and west. The north China plain extends for the most part less than 400 mi. from the

coast, and beyond are the rugged uplands of Shansi, Shensi and Kansu. Most of this northwest area, sometimes called "Loessland," is overlain by a thick mantle of fine-grained wind-deposited alluvium, or loess, between 50 and 250 ft. deep. The landscape has a characteristic carved appearance, since the loess is easily etched and dissected by erosion. This loess soil is highly fertile and, where water is available, very productive, but both rainfall and water for irrigation are scarce; there is also relatively little land level enough for cultivation, and the greater part of it lies in the northwestern section where rainfall is least. Cultivation has made increasing use of the hillsides, usually by means of terracing, though even in this form it does not prevent erosion of the soft loess. Irrigation water is most often available only in the deeply entrenched stream valleys, and hence cannot generally be used for cultivation on the interfluvial uplands despite the fertility of their soils. Wind-deposited loess occurs also outside Loessland proper, notably in a relatively thinner cover over most of eastern Honan seaward from the Fu Niu Shan; as a secondary fluvial deposit it is spread more uniformly over the north China plain, mixed with other Hwang silt, and thus augments the fertility of this lowland area.

In the east, the north China plain encompasses one of China's major concentrations of settlement and agriculture. Fertile soil and low relief combine to outweigh the manifold disadvantages of aridity. Proximity to the sea helps to make up for the lack of inland water transport, and over this generally dry and level land roads are easily built. A considerable volume of trade moves overland between the northwest and Tientsin, the commercial and industrial centre of north China and, after neighbouring Peking, the leading railway centre of China proper. A narrow coastal corridor between the sea and the mountains of Jehol links the north China plain with the plain of southern Manchuria. It has been a persistent route of invasion and became the focus of rail lines linking Manchuria with China.

In central and south China east-west topographic distinctions are less strong but still apparent. In the western half there are only rare and limited breaks in the jumbled sea of mountains which covers the area, while in the eastern half the Yangtze has created an extensive lowland as far west as Tungting lake, 700 mi. from the sea. In the south the Si Kiang has duplicated this pattern on a much smaller scale. It is nevertheless true that south China as a whole is a land of mountains and that it contrasts markedly with the more uniform and level terrain of much of the north.

There are very few well-defined mountain ranges within China proper. Where they occur, their effects are the more pronounced. The Tsinlingshan, running roughly east and west from southeastern Kansu to central Honan, where it largely disappears, marks one of the sharpest physical and cultural lines in China, between the dry brown plain of the north and the green hills of the south. Farther eastward, however, there is no such striking demarcation, though the Hwai Yang Shan along the provincial boundary between Honan and Hupeh helps somewhat to carry on the north-south boundary. Beyond Nanking begins the open coastal plain, where the old deltas of the Hwang merge with those of the present Hwai and Yangtze and north and south meet unhindered over a wide zone of transition. Central China, or the Yangtze basin, is in many respects not only transitional between north and south but a distinct geographic region. It lacks both the aridity of the north and the excessive relief of the south; its lowlands include not only the delta and lacustrine plains farther upstream but also the Red basin of Szechwan, considerably less level but one of China's primary areas of settlement and agriculture. There the Yangtze emerges from the plateau escarpment of the mountain mass of central Asia and is joined by three major tributaries; the rivers have between them carved out an extensive and fertile basin, and their continuing role in the province, China's largest in terms of both area and population, is revealed in the name "Szechwan," which means four rivers (the Min, Lu, Kialing and Yangtze).

South of the Yangtze basin the only significant gaps in the confused mass of mountains are the delta of the Si and the succession of smaller flood plains and deltas northward from Canton along the coast. Running roughly northeast-southwest approximately 200 mi. inland from this coast are the only major discernible ranges in south China, the Wu Kung, Ta Yü and Yün Ling. Difficult, broken country, however, extends almost to the coast between Hangchow and Swatow, and this succession of barriers has tended to cut off southeast coastal China from the main body of the country, to the extent that many of the people are either non-Chinese in origin or still retain a different language or dialect. The drowned coast line includes many fine harbours, and this is China's maritime region, with long-standing commercial relations overseas, a large investment in trade, shipping and fishing and a virtual monopoly of overseas emigrants. This is also the only significantly forested area of China proper, and while the stands are difficult of access on the steep slopes which cover the region and their total is not very large, their timber helps to support the fishing and trading specialties and is also a leading export.

A second discernible topographic region in the south is the misnamed "plateau" of Yünnan and Kweichow in the southwest. It is so heavily dissected that the term "plateau" hardly fits the case; level land is almost as scarce there as in the southeast and is for the most part confined to a series of old intermontane lake beds now largely dry. The area owes its distinction to remoteness, to a dry climate, to a high average elevation (over 5,000 ft. for most of Yünnan) and to the consequence of its high relief in the fact that Chinese settlement has not yet spread significantly into the hills, which are still occupied by non-Chinese tribes. This country, in effect the foothills of the great Tibetan escarpment, actually continues northward through the western part of Szechwan and into Kansu. The southwest has periodically enjoyed closer relations with the Indochinese peninsula (to whose present inhabitants the non-Chinese tribes of the southwest are closely related) than with China, though access even in this direction is difficult. The gorges of the Salween, Mekong and lesser streams, plus the tropical rain forest and climate, interpose a formidable barrier.

Chinese occupation of the land south of the Yangtze basin did not begin until about the Christian era and is still not complete in the southwest. Its slow and often-interrupted progress during 2,000 years is a reflection of the basically inhospitable nature of the land for agriculture. The non-Chinese linguistic or ethnic islands in the southeast and southwest are samples of what mountains and isolation have made of the pattern of human occupancy. The only easy overland connection, and by far the most important, between the south and the Yangtze basin is the twin route leading from Canton via the Pei (North) river or one of its tributaries and across one of two low saddles into the headwaters of the Siang or Kan rivers, each leading to the Yangtze. These mountain passes, Cheling (1,400 ft.) and Meiling (1,000 ft.), have helped to keep Canton in much closer relationship with the rest of China than has been possible for most of the south, and have implemented Canton's traditional function before 1842 as the overseas trade centre for the whole of China, despite its off side location. Modern China's only direct north-south rail line from Peking via Hankow to Canton runs through the Cheling pass.

The Coast Line.—China's north-south dichotomy is reemphasized by the break in the nature of its coast line which occurs in the area of Hangchow bay. South of this area is a submerged coast with numerous good natural harbours, while to the north an emergent coast line provides almost no naturally usable harbours with the exception of the rocky promontory of Shantung. Shantung, originally an island in the Yellow sea, has been tied to the land by silt deposition from the Hwang, but the general lack of easy transport connections with the hinterland, especially by river, has greatly reduced the usefulness of the major harbours at Tsingtao and Chefoo. Elsewhere along the north China coast the originally poor harbours are continually menaced by silt from the arid-climate rivers and from the Yangtze in the case of Shanghai. Tientsin, 40 mi. from the sea on the Pei river, was forced to remove its port to Taku-Tangku at the river's mouth, but even there sand bars made it necessary for deep-draught shipping to

load and unload by lighter at sea. The Communist government built an artificial harbour near Tangku, but it was too shallow for large transpacific shipping. Shanghai's problem is less crucial but still serious. Other north China ports such as Sinhai (Tunghai or Haichow) and Chinwangtao have had to rely on artificial harbours as well as on constant dredging.

What south China gains in number of good harbours it largely loses in ports which are inaccessible to a productive hinterland because of mountain barriers and lack of navigable inland waterways. The Si makes Canton an exception, though its deltaic harbour is poor, and also accounts substantially for the commercial prominence of Hong Kong, a rocky island off the mouth of the Si with a large and deep protected roadstead. However, not Hong Kong but Shanghai, despite its poor harbour, is normally by far the largest port in China, by virtue of the Yangtze river and its access to a huge, productive hinterland.

Climate.—It is difficult to generalize about so large an area as one which contains such climatic extremes. North China as a whole has a continental climate of hot summers and cold winters, with the extremes becoming more pronounced farther inland. Continentality is accentuated by the monsoon wind system of east Asia which, while less marked than in south Asia or India, produces in north China predominantly inblowing, warm maritime airs in summer and predominantly cold, dry, outblowing airs from Siberia and inner Asia in winter. The mountains of the northwest tend to exclude the maritime airs (which bring moisture as well as warmth), and their penetration is further offset by the counterinfluence of the warm Kuro Shiwo or Japan current off the coast. Close to the sea, in the eastern sections of the north China plain, winters are relatively mild, with only one month having an average temperature below freezing. This area also receives the inblowing summer winds from the sea in fair amount, and, while the rainfall which they bring to north China is highly unreliable, their southeasterly origin makes for a summer which at its height is nearly as warm as that in south China, although less prolonged. In the northwest winters are rigorous, in the full grip of the outblowing airs from inner Asia, and summers are considerably cooler than on the plain.

North China's great climatic problem is rainfall. This is everywhere a marginal area, more because of the great yearly fluctuation in precipitation than because of the average annual amount. Average annual variability in north China as a whole is approximately 30%; in the loess area of the northwest it reaches 40%. With an annual rainfall average for all north China of between 20 and 25 inches, this is a precarious situation. Annual variability frequently matched by seasonal variability, which can be fully as serious. Considerably more than half the annual precipitation usually comes in June, July and August, when it is most needed for the planting season and the early growth of crops. But it is often delayed beyond the end of the planting season and may either largely fail or come so late that it is of no use for the current agricultural year and instead produces disastrous floods. Unfortunately the population of north China has increased up to the maximum for optimum climatic conditions, and in at least one-third of the years conditions are far from optimum. Hence the cruel and long-established cycle in north China of one major famine approximately every three years, periodically worsened by floods. Winter precipitation is far too slight to support crops even if the temperatures allowed it, although the thin and sparse winter snows occasionally help to moisten the soil for spring. The winter winds from inner Asia, however, are mainly dry, and their violence picks up clouds of dust from the loess highlands and the bare parched plain to make dust storms a prominent feature of all north China from October to April. The north depends on drought-resistant crops rather than on rice—wheat, kaoliang and millet most importantly. No part of the north has adequate rainfall but the western parts, farther from the sea, are especially arid: for the north China plain alone the annual average is about while for the loess highlands it is about 15 in.

The isohyet (line) of 40 in. annual rainfall runs in the eastern of China roughly along the valley of the Hwai river, and in the west through northern Szechwan. South of this line rainfall generally is adequate and reasonably reliable. Average annual variability is less than 15%. Seasonal distribution is also favourable, with a peak in June-July-August but with adequate and reliable amounts occurring throughout the year, including the winter months. This and the mild temperature regime make winter crops possible and largely save south China from recurrent famines. Annual rainfall reaches and exceeds 70 in. in parts of Kwangtung and Fukien, but the general average for China south of the Yangtze (exclusive of the southwest) is about 55 in. During the summer months this is likely to come as heavy showers, and, given the relatively high annual total, the soils of south China are badly leached. Winters are mild, though in the lower Yangtze basin the Siberian high penetrates enough to put average temperatures for three months into the 40's and to make many dry, clear, cold days or nights with temperatures below freezing. Nevertheless the growing season in the Yangtze basin averages more than 300 days, and winter crops, especially of beans or wheat, are universal.

In Kwangtung, Kwangsi and Fukien, while there may be occasional frosts, there are barely two months with average temperatures under 60°, and the growing season is virtually unbroken, allowing two crops of rice per year plus a winter crop. Summer in the south is hot, humid and long; Kwangtung and Kwangsi have four months with average temperatures over 80°, which is not surprising considering the southeasterly origin of the prevailing summer winds and the fact that Canton itself lies 21 mi. S. of the Tropic of Cancer. At the other extremity, Szechwan and the lower Yangtze basin each have three humid months over 80°, although the maxima are less than for Kwangtung and Kwangsi.

This temperature and rainfall regime is the result of a modified monsoonal wind system, plus a cyclonic pattern which moves over China especially in winter from west to east. The major cyclonic storm track follows the Yangtze valley, bringing the gentle *pai yü* (plum rains) in early and middle spring to coincide with the rice-planting season. Winter rains of both cyclonic and maritime origin are general over most of south China, and there is no marked dry period. Mountain protection and the influence of the sea help to exclude the Siberian high and to keep southern winters mild. Even Szechwan, far from the sea but ringed by high mountains, has a generally milder winter than the relatively open plain of the lower Yangtze. The great and destructive climatic anomaly of the south is typhoons, although they are largely limited to the coastal strip south of Shanghai. They quickly lose their violence inland from the coast, and north of Shanghai they are infrequent and not severe. Typhoons may occur throughout the year along the southeast coast, but they are commonest in late summer (mid-July to mid-September); they account for much of the summer rainfall as well as damage to coastal shipping and settlement.

The southwest is climatically a distinct region; its mountain barriers and distance from the sea keep it on the fringes of monsoonal influence, and it is also off the track of most of the cyclonic storms. Average annual rainfall (derived from both the Indian and Pacific oceans) is about 40 in. but is markedly concentrated in summer; for the balance of the year it is minimal, and the winter and spring landscape is bare and brown enough in the western sections to be reminiscent of north China. However, its southerly latitude and degree of mountain protection against the Siberian high keeps winters mild, and only two months have average temperatures under 50°. In summer the hot, humid maritime airs seldom penetrate, and the generally high average elevation helps to produce a cool and bracing atmosphere. Yünnan and eastern Kweichow should be distinguished climatically, the latter having slightly greater precipitation but many more rainy days, which are less strongly concentrated in summer, and lacking the higher elevations of Yünnan. Yünnan is famous for its magnificent cumulus clouds and bright blue sky (the name may be translated as "south of the clouds" or "southern cloud land"), which contrast sharply with the gray, dripping winters of neighbouring Kweichow and Szechwan and which are suggestive of a semineutral position between monsoonal and cyclonic influences.

Regional Summary.—On the basis of the foregoing sections, China may grossly but usefully be divided into six major regions, characterized in brief as follows:

1. The north China plain (Hopei and parts of Shantung, Kiangsu and Honan): semiarid, level, rich alluvial soil, dense agricultural settlement, several prominent trade and manufacturing centres; the consistent military and political focus of China and with most of its railways.

2. The northwest, including the loess area (Shansi, Shensi, Kansu and parts of Honan): arid, deeply eroded mountains, severe continental climate, rich loess soil, relatively sparsely populated, few large cities or railways; the vestibule of China's gateway to the west and probably the site of the earliest Chinese civilization.

3. The Red basin of Szechwan: moderate climate with adequate rainfall, moderate relief (dissected by four rivers), including several densely settled agricultural areas; demarcated and isolated by mountains on all sides, but tied to the east by the Yangtze; a few large trading cities but little manufacturing.

4. The lower Yangtze basin (most of Hupeh, Hunan, Anhwei, Chekiang, Kiangsi and Kiangsu): moderate climate, much level alluvial land, very dense agricultural settlement and heavy rice production; China's major trade artery, with many large commercial and manufacturing cities, including Shanghai.

5. The southeast (Kwangtung, Kwangsi, Fukien and parts of Chekiang and Kiangsi): subtropical climate, heavy relief, isolated by mountains and oriented to the sea, very dense agricultural settlement on the deltas, sparsely occupied uplands, series of maritime trading centres along the coast; retains many non-Chinese features.

6. The southwest (Yünnan and parts of Kweichow and Szechwan): moderate, bracing climate, fairly heavy relief, isolated by mountains and distance, Chinese occupancy largely confined to the occasional intermontane basins, few large cities, little trade or manufacturing, very sparse non-Chinese settlement on the uplands; connections with the Indochinese peninsula. GEOLOGY

The geological pattern of China and its dependencies is determined by two series of structural axes, one extending east-west in central Asia and the other northeast-southwest in the coastal regions. The more important and more recent axes are marked by mountain ranges. They intersect and interfere with one another in much of China proper, produce many complexities and enclose several important structural and depositional basins, such as the Red basin of Szechwan and the Shensi basin to the north, and the modern alluvial areas in the lower Hwang and Yangtze river valleys, as well as many smaller ones.

The earth movements, involving both folding and faulting, responsible for the present geological structure began in very ancient times and have continued at intervals to the present. The most important were: (1) pre-Cambrian (widespread, in several stages); (2) post-Silurian (minor except in south); (3) post-Devonian (in southeast); (4) Upper Carboniferous (in southwest and in Nan Shan, where granite intrusions are numerous); (5) mid-Permian (Kuen-lun mountain axis and its extension into central China, lava flows in southwest); (6) post-Triassic (general uplift of eastern Asia, folding in southwest and east central China); (7) post-Jurassic (widespread, most important in Tsinling axis of central China); (8) post-Cretaceous (widespread, lava flows in Manchuria and southeast China, igneous intrusions in south with which metalliferous deposits are associated); (9) late Tertiary (particularly in north China and Mongolia); and (10) Recent (central Asian highlands).

Because of structural complexity, rocks of all geologic ages are widely but irregularly distributed, and the only considerable areas of comparatively undisturbed strata occur in the basins. The total thickness of sedimentary rocks is very great, but in a country of such size the thickness and also the lithologic nature of beds of equivalent age vary greatly in different areas.

The pre-Cambrian rocks constitute three great systems: Tai Shan (oldest), Wutai and Sinian (youngest). The first consists of highly metamorphosed sedimentary and igneous rocks, mostly gneiss and schist, and the second is made up of less metamorphosed sediments. The last is mainly sedimentary and consists of arkosic clastics below grading up into thick cherty limestone; it also includes sedimentary iron ore, tillite and local lava flows. These are unmetamorphosed except where involved in much later mountain-forming disturbances and generally resemble overlying Palaeozoic formations.

The Palaeozoic succession begins with Lower Cambrian sandstone and grades upward into thick later Cambrian and Ordovician limestone. Toward the end of the Ordovician period all China north of the Tsinling axis was gently uplifted, and subsequent deposits are absent from that region.

Silurian, Devonian and Lower Carboniferous strata are confined to south China and include graptolite-bearing shale (Silurian), plant-bearing nonmarine beds (Devonian) and much limestone. The lower parts particularly were deposited in very shallow water.

Upper Carboniferous strata overlap extensively onto Ordbvician and older rocks in north China, and Permian strata are almost equally extensive. In south and central China these beds are mainly limestone, but in the north they include the most important coal deposits of the country, and red beds become conspicuous in the upper part.

Sinian and Palaeozoic sediments accumulated in a broad depression extending northeast-southwest and connecting with similar east-west depressions on either side of the Tibetan region. Successive mountain uplifts encroached upon these depressions and reduced in size and multiplied in number the depositional basins of later times, which shifted to some extent with respect to each other.

Nonmarine strata become progressively more important in the Mesozoic, and thick red beds are present in many areas. Rock salt occurs in the Triassic of Szechwan, coal in the Jurassic and gypsum in the Cretaceous.

Tertiary strata, mostly nonmarine red beds, occur especially in the north, where they are many thousands of feet thick. They include some lignite, gypsum, fresh-water limestone and lava flows. The youngest of these beds are nearly horizontal except adjacent to very recently uplifted mountains. Oil is produced from the Tertiary in the northwest.

Deposits of Pleistocene and Recent age include thick piedmont gravels in central Asia, the loess of north China and extensive alluvium in the Hwang, Yangtze and other river valleys.

ANIMAL LIFE

Profusion of vegetation and variety of relief have fostered the development of a fauna of great diversity and have permitted the survival of animals elsewhere extinct. Notable among such survivals are the great paddlefish (*Psephurus*) of the Yangtze, the small species of alligator in east central China and the giant salamander (related to the Japanese giant salamander and the American hellbender) in western China. The diversity of animal life is perhaps greatest in the ranges and valleys of the Tibetan border, to which region the remarkable giant panda is confined. The takin or goat antelope, numerous species of pheasants and a variety of laughing thrushes are to be found in all the Chinese mountains. China seems to have been one of the chief centres of dispersal of the carp family and also of old world catfishes.

The regional affinities of the Chinese fauna are complex. In

the northeast there are relations with the animal life of the Siberian forests. The Mongolian deserts bring animals from central Asia into suitable steppe areas in northern China. The life of the great mountain ranges is Palaearctic, but with distinctively Chinese species or genera. To the southeast, the lowlands and mountains alike lead directly into the oriental region. This part of China presents a complete transition from the temperate zone Palaearctic life to the wealth of tropical forms distinctive of southeastern Asia. Tropical types of reptiles and amphibians and of birds and mammals predominate in the southernmost Chinese provinces. (K. P. S.)

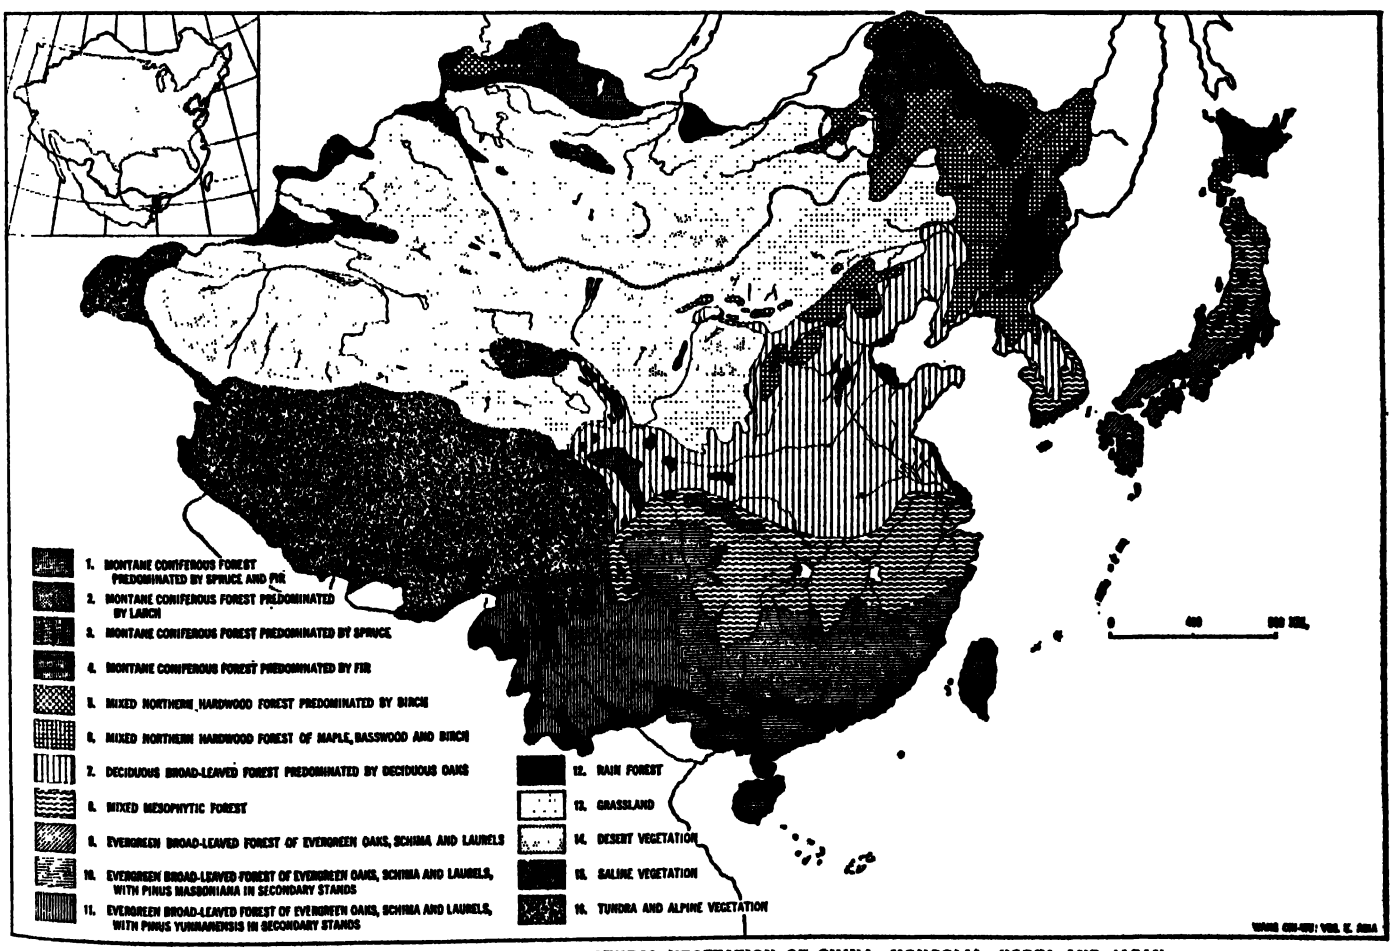
VEGETATION

The natural vegetation of China ranges from boreal taiga to rain forest and from barren tundra and desert to the littoral vegetation of the coral islands in the tropical seas. In general, the entire territory of China is dominated by two great plant formations: the grassland-desert of the northwestern half of China and the woodland of the southeastern half.

Six major forest types are recognized:

1. The mixed northern hardwood forest is best developed in the northeastern provinces. A similar type appears also in the higher elevations of the northern provinces above the deciduous oak belt. The primary components are maple (eight species), linden (five) and birch (nine), intermixed with white pine (*Pinus koraiensis*), oak, walnut, *Maackia, Phellodendron,* elm, *Kalopanax* and other minor accessories.

2. The deciduous oak forest is the major type of the northern provinces. Relics of natural forest indicate that the primary components are *Quercus aliena, Q. liaotungensis, Q. dentata* and *Q. variabilis.* The common associates are ash, hornbeam, elm, *Pistacia, Prunus,* walnut and hackberry. Pine (*Pinus tabulaeformis*), arborvitae and juniper grow on exposed ridges. The denuded slopes are covered with *Vitex, Zizyphus, Lespedeza,* grasses and thickets of *Cotinus, Deutzia, Spiraea,* wild roses and lilacs.



3. The mixed mesophytic forest of the Yangtze valley is richest in composition of all the deciduous forests. Preserved in this temperate clime are a number of relics of Tertiary flora (notably *Ginkgo, Metasequoia*) of more than 60,000,000 years ago, and polytopic genera which are represented also in North America (*e.g., Liriodendron, Sassafras, Cladrastis, Gymnocladus*). The forest components include: *Aesculus, Aphananthe, Carya, Castanea, Cephalotaxus, Cercidiphyllum, Cryptomeria, Cunninghamia, Cupressus, Daphniphyllum, Diospyros, Ehretia, Emmenopterys, Eucommia, Fagus, Fraxinus, Halesia, Idesia, Magnolia, Nyssa, Paulownia, Pseudolarix, Pseudotsuga, Quercus, Torreya, Trema and Zelkova.*

4. The evergreen oak forest extends over the hilly areas of the southern and southwestern provinces, Taiwan and Hainan Island. It is composed of more than 150 species of evergreen cupuliferous trees (*Quercus, Pasania, Castanopsis, Castanea*) and numerous evergreen trees of the Lauraceae, Theaceae, Magnoliaceae and Hamamelidaceae. Bamboo and secondary growth of *Pinus massoniana* and *Liquidambar* cover large areas south of the Yangtze.

5. Rain forest occurs only along the southern fringe of China from the Yünnan-Assam border to the lowlands of Kwangtung, Hainan and Taiwan.

6. The montane coniferous forest of the Greater Hsingan range is essentially of larch (*Larix gmelini*), but spruce (*Picea obovata, P. jezoensis*) and fir (*Abies holophylla, A. nephrolepis*) form dense forest on the eastern rampart bordering Korea. The montane coniferous forest of the southwestern plateau is composed of a multitude of conifers, including spruce (eight species), fir (ten), hemlock, larch and *Pseudotsuga.* Montane coniferous forests appear also on the high peaks of the northern provinces (*Picea asperata, P. neoveitchi, Abies nephrolepis*), Sinkiang (*Picea schrenkiana*) and Taiwan (*Picea morrisonicola, Abies kawakami*), right under the Tropic of Cancer.

A vast expanse of grassland extends from the plain of the

DISTRIBUTION OF THE MAIN TYPES OF NATURAL VEGETATION OF CHINA, MONGOLIA, KOREA AND JAPAN

northeastern provinces westward to the Tien Shan, interspersed with salt lakes (*nor*), gravel desert and sand dunes. Thick clumps of *Stipa splendens* are the most conspicuous feature. The arid areas support only xerophytes and halophytes. Orchards, vineyards and luxuriant groves of poplar and elm, however, thrive in the oases. Marshes of cattail and *Phragmites* teem with nesting geese, ducks and swans in summer. The vegetation of the Sidzang plateau (Tibet) is scanty, consisting only of scattered cushion plants with thick rootstocks. But the Tsangpo (upper Brahma-putra) valley is well wooded. Rice and corn are planted successfully in Zayul district. (W.)

ARCHAEOLOGY

To the Chinese scholar up to the 20th century, archaeology was a discipline closely linked with historical and literary studies. Archaeological materials were valued according to whether they verified or illustrated the past as encompassed in the classics and annals. Epigraphy, therefore, naturally became all-important, while objects without inscriptions were neglected. Thus the documents of the scriptless prehistoric past remained practically outside the sphere of scholarly research in China until duly authorized westerners began to organize explorations in the field from about the early 1920s onward. Their activities, soon shared by the Chinese themselves, resulted in geological, palaeontological and archaeological discoveries of the utmost importance. Progressing at a fast pace, these activities came to a standstill when the Chino-Japanese War started in 1937. Much of the material which had accumulated up to that time became accessible in publications and discussions carried on later.

Palaeolithic in North China.—The famous site of Chou-k'ou-tien, about 30 mi. S.W. of Peking, was first investigated in 1921 and in part excavated between 1923 and 1937. It is a limestone hill with fossiliferous deposits ranging from the Miocene (sandstone fish pocket, Locality 14) to the end of the Pleistocene. The remains of *Sinanthropus pekinensis* and his primitive industry came from two strata (sands and breccias, *Hyaena sinensis* zone; overlaid by ashes and travertine, *Hyaena ultima* zone) of the deep fissure of Locality 1, which was sealed by red clays and stalagmitic formations still of middle Pleistocene age. *Sinanthropus* is a hominid who ranks in age with the closely related *Pithecanthropus* of Java. Its discovery had added significance because skeletal fragments and artifacts were found in association. The latter consist chiefly of cracked pebbles and splinters of vein quartz, monotonous and accidental in character. Hand axes (bifaces) are absent. The geologically oldest artifact identified by the mid-1950s came from the red clays in Locality 13; it is a chert chopper reminiscent of the early Soan industry of north India. An advanced lithic technique appears in flaked tools made of various rocks such as those found in the deposits of Locality 15, deposits which consist of red clays still of preloessic age but containing a fossil fauna which points to a geologically younger period than those of Localities 13 and 1. Whether these superior tools, some of which have been compared with Levalloisian flakes, were also made by *Sinanthropus* is a question which for lack of osteological proof cannot safely be answered.

A wide gap separates the finds of the so-called Upper Cave of Chou-k'ou-tien from the preceding finds. Instead of the red sediments there appear the yellow ones typical of the late Pleistocene loess formation. Four human skulls found there revealed the presence of what has been termed an early *Homo sapiens asiaticus*. Cultural remains, poor and atypical in regard to the stone implements, include perforated stone beads and animal teeth, a bone needle and polished objects of bone and antler, which taken together suggest a burial place of some stage comparable with the Magdalenian.

Ordos Industries.—Several important Upper Palaeolithic sites have been discovered along the southern fringe of the Ordos steppe, the area skirted by the great bend of the Hwang-ho. They belong in their entirety in the late Pleistocene, the time of the formation of the yellow earths (loess), but vary in age. None of them yielded skeletal remains of man. A series of very hard quartzite implements, mostly made of round pebbles chipped along one edge, as well as some flakes, came from the basal gravels underneath the loess, the maximum thickness of which does not exceed, according to Pierre Teilhard de Chardin, 50 m. and often is far less. Finds of this category were reported from Ch'ing-yang-fu, Yu-fang-t'ou, Chungar, Pao-te and Wu-pao. In the loess stratum itself, two dwelling places and workshop sites were explored: Shui-tung-kou, close to the Hwang-ho opposite Ningsia, and Sjara-osso-gol, southeastern Ordos.

Shui-tung-kou.—This is a loess-filled depression, stretching east-west for 10 mi., where five hearths with ashes and a great number of artifacts were located at various depths in a stratum of loess measuring 15 m. A rich and diversified lithic industry comprising such types as scrapers, points and gravers reminiscent of Mousterian and Aurignacian types suggests a stage more developed than that of the aforementioned group; yet tools of the primitive "Soan chopper" variety occurred in the same assemblage. The materials used, chert and silicified limestone, were taken from the gravel of streams embedded in the yellow loam which were later buried under renewed deposits of aeolian loess dust.

Sjara-osso.—The site of Sjara-osso is remarkable on two accounts; viz., the extraordinary depth of the fossiliferous beds of dune sands and lacustrine clayey sediments overlying the Palaeolithic floor, and the smallness of the lithic implements, chiefly scrapers and points, made of small siliceous pebbles such as are available in this area. Typologically, this "micro-industry" is considered by Henri Breuil as advanced beyond the Shui-tung-kou stage. However, it is separated from the Neolithic horizon of the same site by no less than 55 m. of deposits, sands and sandy clays rich in fossils (*Rhinoceros tichorhinus, Equus hemionus, Bos primigenius*). The absolute age of both Shui-tung-kou and Sjara-osso is about 50,000 years, according to J. G. Andersson, whose estimate of the age of the Upper Cave of Chou-k'ou-tien, referred to above, is about 25,000 years. Much older is the industry of *Sinanthropus,* which in the same system is placed around 500,000 years ago.

South China.—Except for some isolated finds of probably late Pleistocene stone implements, south China has offered little beyond promises of future discoveries. Ancient sites or workshops remain unknown. The finds reported by the mid-1950s were some flakes collected from loess deposits in the area of Ta-tien-lu (western Szechwan); a chipped flinty tool found at the surface of the Yangtze terraces near Wan-hsien (Szechwan); strongly weathered chipped quartzite implements embedded in conglomerates of limestone and river gravels in the Yangtze gorges above I-ch'ang; and a quartzite chopper (?), heavily rolled and apparently reworked by Mesolithic cave dwellers of Kwangsi, which has some claim to be the oldest implement so far encountered in south China.

Mesolithic Phase.—A Mesolithic phase comparable with that of post-Pleistocene Europe has not been identified in China proper. In the southerly province of Kwangsi, however, a possibly Mesolithic culture was discovered in cave deposits of perhaps still late Pleistocene age but devoid of remains of extinct animals or any strongly fossilized bones. It is a pebble industry including crude types of choppers, scrapers, hammerstones and, occasionally, perforated stones. Polished or only partly polished stone implements and pottery are absent. The stage is comparable with, and probably related to, the early Bacsonian of neighbouring Tongking.

In the northern borderlands—Mongolia and Manchuria—geographic and climatic conditions of the postglacial period apparently favoured the development and spread, over millenniums, of a culture of hunters, and later of primitive farmers, who have left abundant traces of their culture in microlithic tools made of fine minerals such as jasper, agate, carnelian, chalcedony and flint. The commonest shapes among those tools are small and

slender flakes and the conical cores, or micronuclei, from which these flakes were obtained. The foremost site in Mongolia is that of Shabarakh-Usu in the Gobi desert. Widely diffused to the east, into Manchuria, and southward (Ordos), and no doubt related to Siberian microlithic cultures, this Shabarakh or Gobi culture corresponds to the Tardenoisian and Azilian of Europe, but differs from the latter in that the "geometric" silices are wanting. In regard to China it should be observed that microlithic chipped implements are not encountered to the south of the line of the (much later erected) Great Wall; it appears as though this gigantic limes followed a cultural borderline of hoary age and remarkable stability.

Neolithic Stage.—This northern orbit seems to have undergone a gradual transition toward a primitive Neolithic culture of sedentary farmers and husbandmen. This can be observed at two sites in Jehol, Lin-hsi and Ulan Hata (Ch'ih-feng), which were discovered by Émile Licent and Teilhard de Chardin in 1924. The artifacts at Lin-hsi were found either embedded in a post-Pleistocene layer of black earth on top of Quaternary white sands above ancient schist, or exposed on the sand where the black earth had been blown away. Crude rhyolithic pebble tools and blades as well as nuclei of fine siliceous rocks occurred side by side with grinding stones and pestles usually made of granite. A few hoelike implements and perforated round pebbles were recovered. Polished implements were rare, and true axes or celts were absent. The pottery encountered in the stratum of black earth was a hand-made, poorly fired ware. Bones of the domesticated horse, ox and sheep, but none of wild game, were found.

Geologically and archaeologically similar conditions prevail at the site to the south of the "red rock," which gave Ulan Hata its name. In addition to the Lin-hsi inventory mentioned above, however, this site yielded rather advanced types in stone as well as pottery, the later age of which seems unquestionable but could not be ascertained stratigraphically. To these later types belong more or less wholly polished hatchets; a polished, rectangular ax with perforation; broad knives with perforations; and stone beads. In pottery there appeared round, obtusely pointed solid legs of tripods, as well as vases of fine red clay, occasionally with a white slip and, most characteristic, with spiral decoration painted in black.

The "Mongolian Neolithic," typified by the presence of microliths agricultural tools and some pottery such as are known from Lin-hsi, expands north into north Manchuria (Hailar; Ang-ang-ch'i near Tsitsihar), where it assumes or retains a character that has been described as Maglemosian, since the finds speak of a stronger dependence on fishing and hunting there; farther west it was traced in the Gobi (later Shabarakh) and southwest in the Ordos (Sjara-osso, surface finds). This culture, which must have comprised the wide territories to the north of the yellow clay or loess of China proper and to the south of the Siberian forest zone, seems to have vanished without further local developments, presumably because of an increasing desiccation and the desertlike conditions resulting therefrom. Some traces of it were found in sites spreading between western Kansu (Chu-chia-chai; Lake Koko-nor) and the Gulf of Liaotung (Shakuo-t'un in Liaoning), where—similar to what was noted in Ulan Hata—a new late Neolithic culture with painted pottery and polished stone tools supervened. These "mixed sites," on the whole, have to be understood as evidence of an expansion of the new culture into the southern fringes of the territory previously and perhaps still held by the makers of the microliths.

The rare case of what appears to be an intrusion of north Eurasian *Kammkeramik* in a south Kansu site (Ch'i-chia-p'ing) visited and described by Andersson, a ware with comb stamped ornaments entirely foreign in China, probably belongs in the period preceding the appearance of the painted pottery.

Yangshao Painted Pottery Culture.—The period between the late Palaeolithic of the Upper Cave at Chou-k'ou-tien and the appearance of the Painted Pottery or Yangshao culture in north China, a period of many millenniums, is (in contrast with Mongolia) archaeologically obscure. Except for a series of limestone and quartzite artifacts of Palaeolithic character collected by C. C. Young and W. C. P'ei at Yang-shao-ts'un in 1934, there are no finds to shed light on that long period. But this is an isolated and puzzling case which does not go far in altering the apparent fact of an archaeological blank, Andersson's "Neolithic hiatus." Climatic conditions may account largely for this hiatus. The final Pleistocene, when the loess formation was still in progress, was a cold and semiarid phase; afterward, in postglacial times, the river valleys and plains may have been swamplands.

> Then suddenly, at the very end of the Neolithic, at a time only four thousand years distant from our own, the hitherto seemingly empty land becomes teeming with busy life. Hundreds, not to say thousands of villages occupy the terraces overlooking the valley bottoms. Many of these villages were surprisingly large and must have harboured a considerable population. Their inhabitants were hunters and stock-raisers but at the same time agriculturalists, as is evidenced by their implements and by the finding of husks of rice in a potsherd at Yang-shao-ts'un. The men were skilled carpenters and their womenfolk were clever at weaving and needlework. Their excellent ceramics, with few or no equals at that time, indicate that the then inhabitants of Honan and Kansu had developed a generally high standard of civilization. There must have been, by some means or other—new inventions or the introduction of new ideas from abroad—a rather sudden impetus that allowed the rapid spread of a fast growing population. (From J. G. Andersson, *Researches into the Prehistory of the Chinese*, Bulletin of the Museum of Far Eastern Antiquities, no. 15, p. 297 [Stockholm, 1943].)

It was in 1921 at Yang-shao-ts'un (Mien-ch'ih-hsien, western Honan) that Andersson discovered the culture so succinctly described in his above-quoted words. Further explorations revealed that this culture had covered the wide area between western Kansu and northern Honan, with extensions into Szechwan, Jehol and Liaoning, and that the ancient settlements were close to the rivers Hsi-ning, T'ao, Wei, upper Kialing and Han and to the Hwang-ho where it flows eastward after the great Ordos bend. The surprising and basic fact arising from this discovery is that China falls in line with west Asian and Indian sequences. For not only does there appear in China a painted ware, but, exactly as in the west, this ware is gradually replaced by a burnished black ware. This is, or was, however, a complicated process, far from being clarified by adequate field work. The observations made up to the mid-1950s are summed up in brief below.

Stratigraphy.—In most of the dwelling sites explored, the cultural stratum was rather shallow, but in two very large ancient villages, Hsi-yin-ts'un (southwestern Shansi) and Yang-shao-ts'un (western Honan), partial excavations revealed cultural strata varying between 2.50 to 4.00 m. and 2.50 to 3.00 m., respectively. However, judged by the occurring types of pottery shards, no clear subdivision or stratigraphic sequence was seen in either place. Andersson stated that Yangshao represents one single cultural stage comprising both painted and burnished black wares. The only stratigraphic change noted by P. L. Yüan, Li Chi and Liang Ssu-yung at Hsi-yin-ts'un in 1926 was a slight increase in the percentage of the black shards as compared with the painted shards in the upper layers, while the percentage of the cruder pottery, gray and reddish, with or without cord impression, remained constant throughout. In a few northern Honan sites, on the other hand, excavated by staff members of the Academia Sinica in 1931 and 1932, a stratigraphic sequence of painted pottery overlaid by black pottery and, topmost, gray Shang pottery was observed (Hou-kang, 1931; Kao-ching T'ai-tzu near Hou-chia-chuang, 1932; Ta-lai-tien near Hsün-hsien, 1932). In other sites in northern as well as western Honan, however, black pottery associated with, or overlaid by, gray pottery but with no trace of painted pottery was found to be a recurring and typical assemblage (Ssu-p'an-mo and Huo-chia Hsiao-chuang, near An-yang, north Honan; Pu-chao-chai, Yang-ho-ts'un, Hsi-chun-ts'un, in west Honan). Field observations made in the upper Wei valley by W. C. P'ei in 1947 tended to show that the ceramic wares in the many prehistoric sites of that area—the main route from Kansu to Honan—suggest three stages, early, middle and late, characterized by painted pottery first of good style, then of degenerate style and finally by the utter decay and disappearance of the painted pottery. From Kansu came the finest of the painted ceramics but little of stratigraphic interest. No more than two significant observations can be reported. Andersson

noted at Hsin-tien (T'ao river valley) that Yangshao ware was overlaid by a stratum of Hsin-tien ware. Hsia Nai, who in 1945 excavated a tomb containing Ch'i-chia pottery as burial gifts (Pan-shan hills, Ning-ting-hsien), picked two Yangshao painted shards from the refill close to the bottom of the pit. Evidently the two shards were manufactured, used and discarded some time before the grave with its entirely different pottery was dug.

From the foregoing notes some inferences can be drawn. In Honan and Shensi, the painted ware preceded, but apparently overlapped with, the black pottery, and the latter in turn preceded a Bronze Age gray ware. In Kansu, where the black pottery seems to be almost absent, only a very few shards being reported, the Yangshao ware is older than the Hsin-tien ware of the beginning metal age and older than the (unpainted) Ch'i-chia ware, which is unknown in Honan.

Painted Pottery Styles.—The phenomenon of clearly differentiated styles of ornament was observed only in Kansu. Named after type sites in Kansu, most of these styles suggest an evolutionary sequence and, consequently, relative dates: (1) Pan-shan, (2) Ma-ch'ang, (3) Hsin-tien and (4) Sha-ching. The Pan-shan style is distinguished by an amphora type, of noble shape and with exquisitely painted ornaments, among which a design of rotatory S curves running horizontally round the vessel predominates. Other frequent patterns are rhombic chequers, diamonds, zigzags and a gourd motif. One tomb of this phase which Andersson was able to excavate at Pien-chia-kou (Pan-shan hills, T'ao valley) contained the skeleton of a man of about 40, in a flexed position and sprinkled with ochre, as well as eight fine painted vases, four crude, unpainted pots and four stone tools. The Ma-ch'ang wares are of reddish clay and are painted, sometimes carelessly, with black ornaments such as large concentric circles, rhombic T hooks and large meander bands consisting of parallel lines; the beautiful dynamic spiral patterns have disappeared. It was with the pottery of the following Hsin-tien stage that some minor bronze objects came to light, none of them, by the way, typically Chinese (Shang). These Hsin-tien wares retain the meander as the predominating motif of their sparse decoration, while their shapes mark a departure from the Pan-shan-Ma-ch'ang tradition. Sha-ching, the fourth phase, appears to have derived from Hsin-tien.

More closely comparable with the repertory of ornamental designs found in Shansi, among which stand out large, flowerlike, sweeping patterns (Ching-ts'un, Wan-ch'üan-hsien, southwestern Shansi), are decorations known from minor find spots in south Kansu. The exact relationship of these latter styles to those of the above-described sequence is not fully clarified, but it appears likely that they postdate the Pan-shan style; they presuppose the spiral motif, which here is transformed into free and asymmetrical curvilinear patterns foreign to the geometric development of the Ma-ch'ang phase.

Ma-chia-yao and Lo-han-t'ang in central Kansu, two large dwelling sites, exhibit designs that may well stand midway between Pan-shan and these south Kansu styles.

The range of ornamental patterns known from Shansi and Honan is comparatively narrow; to put it in the briefest interpretive statement, it may be said that after a splendid manifestation in Shansi (Ching-ts'un and Hsi-yin-ts'un) decline set in in west Honan (Yang-shao-ts'un), followed by a rapid decay in north Honan, so that a loss of diversity and freshness becomes the more noticeable the farther east we move.

Stone Implements.—The following four tools are, according to Andersson, characteristic of the Pan-shan phase: heavy axes of rectangular cross section with rounded-off corners, flat adzes, small adzes and rectangular or trapezoidal knives with one or two perforations. There are pendants and beads of jade, amazonite, turquoise and marble and perforated disks of jade, which in more regular shapes reappear in Shang and Chou times. The techniques of sawing and drilling hard stones thus were familiar to those vase painters. The occurrence of composite tools such as bone knives set with small flint blades (Lo-han-t'ang and Chu-chia-chai, west Kansu) point to connections with the Gobi microlithic cultures.

Lungshan Black Pottery Complex.—It was noted above that a black ware is associated with the painted ceramics in Shansi and Honan. In the eastern provinces of Shantung, Kiangsu, Anhwei and Chekiang, however, only the black wares are found without any traces of painted pottery. The existence of a culture or cultural phase traceable through this black ware became known through the excavation in 1930 and 1931 of Ch'eng-tzu-yai, a mound near the railway station of Lungshan, east of Tsinan (west Shantung).

The typical black pottery is a very thin ware with a blackish or brownish body and a burnished, shiny, black surface. The shapes are distinguished by angular silhouettes that bespeak the potter's wheel. Save for some occasional incised geometric design of great simplicity, there is no decoration. Among the vessels are found types not known in painted pottery, such as tripods, spouted vases with bulbous hollow legs and, most characteristic, bowls on high ringed stems. Specimens of these stemmed bowls were unearthed not only in Shantung but also as far south as the Hangchow bay (Liang-chu, Chekiang) and in westerly Szechwan (Han-chou, north of Chengtu). Sparse occurrences of black pottery have been reported from outlying regions such as northwest Kansu (Chu-chia-chai), south Szechwan (upper Yangtze) and Liaotung (Port Arthur). The centres of the black pottery culture appear to have been located in Shantung and the Huai (Hwai) river valley, areas held by tribes which as late as the Chou dynasty had not yet been assimilated (Tung I and Huai I).

It is certain that the Lungshan culture preceded the Bronze Age level of Anyang (north Honan), site of the last Shang capital between 1300 and 1028 B.C., and that several Lungshan features live on in the Shang culture: bone oracles, shapes of vases (in gray Shang pottery and in bronze) and tamped earth structures. Even so there is no evidence of a genetical relationship between the basically premetallic Lungshan culture and the Shang civilization of Anyang, unless it should emerge with new discoveries relating to the archaeologically still wholly obscure span of approximately two centuries of Shang rule before 1300 B.C.

Chronology and Western Connections.—An earlier Lungshan (I) without metal was found to be separated by a thin, sterile, sandy layer from a later Lungshan (II) with scarce bronze objects at Ch'eng-tzu-yai. It is likely that Lungshan II, as assumed by R. von Heine-Geldern, belongs in the early Shang period (1523?–1301 B.C.), and that Lungshan I accordingly dates from the first half of the 2nd millennium, beginning perhaps around 1800 B.C. Consequently the painted pottery must be placed, in its beginnings in Kansu, around or shortly before 2000 B.C., because its secondary styles in Shansi and Honan overlap with the black pottery.

Both the painted Yangshao and the black Lungshan ceramics appear to have come to China from the west, where possible prototypes of similar shapes, ornamentation and techniques are widespread. In the case of the painted pottery, moreover, an apparent want of archaic forerunners, hence the phenomenon of a sudden unfolding, make it almost necessary to think of outside stimuli. These may have come from Iran, where similar shapes of tripods (Giyan, Djamshidi and Kamterlan), urns (Musyan and Persepolis) and steamers (Giyan) occur, dating from around 2000 B.C., or from south Russia (Tripolye B), where both the shapes of the urns and their *décor* of running spirals offer striking parallels, pointed out by L. Bachhofer, to the Chinese types. For the black pottery, close similarities to north Iranian and east Caspian types of stemmed bowls dating from about 2000 B.C. (Tepe Hissar and Shah Tepe) seem to warrant actual connections through cultural transmissions or, possibly, according to Heine-Geldern, migrations. Even a type of tripod with hollow legs, which is widely regarded as uniquely and specifically Chinese, occurs as far west as Anatolia (Manisa, 3rd millennium).

The approximate dates of the western—Asiatic and European—relevant material agree fairly well with the rough estimates of which the Chinese evidence admits.

Late Neolithic of South China.—The beginning of exploration dates only from about 1932, along the coast between Hong

Kong and Swatow, an area which under the ancient Yüeh had remained independent until as late as 111 B.C., when it was finally subdued by Han Wu Ti. Field observations made by J. Shellshear, D. J. Finn and R. Maglioni (which led to the recognition of several late Neolithic and chalcolithic cultures) were summed up by Maglioni in an attempt to arrive at a coherent if preliminary and admittedly still obscure picture. This includes three Neolithic stages, termed—after a district in Kwangtung—Hoifung (Mandarin: Haifeng) I (Sov), Hoifung II (Sak) and Hoifung III (Pat), and a chalcolithic and bronze period which is but a continuation of the Pat culture modified by the acquaintance with metal. The various stages are differentiated on the basis of the ceramic wares and stone or bronze tools as well as the sites discovered. In most cases these sites revealed objects of only one of the three cultures; among more than 20 sites in the Hoifung district, only two or three showed a mixture of remains of two different cultures.

Hoifung I combines a short ax of lenticular cross section with flattened sides, a derivative of the *Walzenbeil*, as its most typical tool with three kinds of pottery: (1) cord-impressed ware, (2) smoothly finished wares with incised or stamped geometric *décor* around the neck and (3) footed dishes with cutouts in the foot and with red and white paint. This culture is believed to be closely related to Indochina. Hoifung II possesses a wider variety of axes, which again resemble Indochinese types and like these latter are very often ground only near the cutting edge, and leaf-shaped arrowheads as well as stone bracelets. Besides corded ware and another coarse pottery tempered with sand, there appears a fine and thin ware with the *décor* always stamped. A tree pattern deserves to be noted, for it occurs also in the first stage.

The Hoifung III settlements were found almost everywhere near those of the preceding (Sak) phase, pointing to a shift in population, perhaps an invasion. The stone industry differs considerably from the earlier ones. Tools are polished all over, and the finest of them are made of beautiful hard stones or jade. Most typical is the stepped adz with a tang of elliptic cross section distinctly set off from the angular body, a boatbuilders' tool that forms one important link with Neolithic Formosa, the Philippines and Polynesia, while it seems to have remained unknown in northern China. Other polished stone objects such as arrowheads, spearheads and halberds reminiscent of the Chinese *ko* clearly suggest northern connections, and in contrast with the preceding stages there are no Indochinese types present. There is a wide variety of beads, bracelets, pendants and amulets. The pottery of this (Pat) stage likewise exhibits new features. One of them is a stamped "net pattern" of raised lines running obliquely over the surface, a pattern which is paralleled in Ch'eng-tzu-yai, the black pottery site in west Shantung. Others, according to Maglioni, are wares of vitrified clay and even glazed wares, the inclusion of which in this late or post-Neolithic assemblage may need further substantiation. The rise of the Yüeh people is believed to have occurred in the early metal age, partly as a result of ethnic movements and fusions at the time of incipient metallurgy, a factor which transformed the culture termed Pat or Hoifung III without breaking its continuity.

By the mid-1950s no dependable clue had been provided for the chronology of those prehistoric cultures, whose correlations with those of the surrounding areas remained to be clarified.

Early Bronze Age in North China.—This age is likely to antedate the highly advanced stage from after 1300 B.C. known through excavations of the large and rich Shang site near Anyang (north Honan). However, no site of a Bronze Age phase earlier than Anyang has been discovered. Scanty occurrences of primitive metal objects from several painted pottery sites in remote Kansu and Jehol, which probably date from before 1300, shed little light on what happened in the Shang domain before Anyang, say between 1400 and 1300. Those primitive objects consist of single round and conical buttons, compounded buttons, round buttons with striated rims, small buttons in aggregates of six, funnel- and bell-shaped pendants, a bronze armlet with overlapping ends, simple, "shapeless" bronze knives, a thin blade considered to be a razor, small bronze tubes, some arrowheads and the like, such as were found in west Kansu (Hsia-hsi-ho and Ch'ia-yao), central Kansu (Hsin-tien, Hui-tsui and Ssu-wa-shan) and Jehol (Ulan Hata)—a far cry from the elaborate bronze art of Anyang.

Anyang, therefore, appears as an unheralded, surprising and sudden manifestation of Chinese metallurgy as well as of Chinese art forms, which in contrast with the "international" character of the Neolithic potter's art, with its many parallels in western Asia and southeastern Europe, are profoundly dissimilar from those of any other ancient civilization. Even so, some of the outstanding cultural possessions of the Shang people again are paralleled in the west and ultimately may have come thence: the horse-drawn war chariot, a developed system of script and the technique of bronze casting as such.

The excavations carried out by the Academia Sinica in 15 campaigns between Oct. 1928 and June 1937, in an area stretching more than three miles along the Huan river to the west of the city of Anyang, revealed a considerable number of individual sites of varying age and importance. These sites, which are not equally well explored, form, according to Shih Chang-ju, six groups:

1. Hsiao-t'un: large dwelling site of Lungshan and Shang periods. Dwelling, storage and refuse pits; remains of water ditches or canals; pounded earth foundations of houses; foundation burials; individual and collective burials, horse burials, chariot burials and sacrificial burials of oxen, sheep and dogs, all of Shang age; later burials from Sui to Manchu dynasties.
2. Ssu-p'an-mo, Wang-yü-k'ou, Huo-chia Hsiao-chuang: Shang dwelling sites and cemeteries.
3. Hou-kang, Kao-ching-t'ai-tzu, T'ung-lo-chai: three successive stages, painted, black and gray potteries.
4. Hou-chia-chuang (Northwest Hill): Shang cemetery; "royal tombs."
5. Fan-chia-chuang: cemetery, little explored.
6. Ta-ssu-k'ung-ts'un, Nan-pa-t'ai, Hou-chia-chuang "South Field": Shang sites of slightly varying character.

Although the finds were published only in part, enough became known to enable us to form an idea of the range of Shang art and of what either links it to, or separates it from, the past.

Clear links with older cultures exist in the case of the gray pottery, which in a coarsened fashion continues the black pottery traditions. They exist also in the case of many types of bronze vessels, the shapes of which were dependent on then-current pottery prototypes. To ceramic traditions points also a limited but common repertory of geometric ornaments such as diapers, angular meanders and T hooks, found on gray pottery and bronzes as well as on a peculiar new kind of ceramic ware, the Shang white pottery. This is a heavy, hard-fired, whitish ware distinguished by its carved *décor*.

The same white pottery, on the other hand, marks a new departure, being carved in a technique foreign to the Neolithic potters and decorated also with animal images of the abstract, heraldic style that is one of the Shang novelties in archaic bronzes as well as on carved bones and ivories. A bone carver's tradition looms as the uniting agency behind the abstract animal imagery in all those mediums including wood, but the origins of this tradition are unknown. Another new feature is small animal sculptures in jade; they have no precursors whatever in Neolithic sites, while in a general way they are reminiscent of much earlier animal amulets in stone such as were unearthed at Ur, Erech, Tepe Gawra and Khafaje in Mesopotamia.

Among the magnificent bronze weapons of the Shang there are types of tanged axes which appear to be autochthonously Chinese. Others are suggestive of foreign connections. Some rarer types of shaft-hole axes recall designs current in Mesopotamia, Luristan and Persia. The spearheads, socketed celts and certain kinds of daggers and knives, on the other hand, have close analogies in east Russia, Siberia, Mongolia and the Ordos steppe inside the great bend of the Hwang-ho. Conditions thus would seem to repeat a pattern observed when dealing with the Neolithic painted ceramics, which likewise point toward south Russia and the ancient near east as centres of diffusion.

Ordos.—On the evidence of numerous stray finds of bronze objects made there, the Ordos region and adjacent Inner Mongolia form part of the geographical and cultural continuum of the Eurasian steppe belt, an area that was to remain alien to that of the Chinese culture. The Ordos bronzes have close affinities in the Bronze Age inventory of central and south Siberia (Minusinsk, Tomsk, Altai and Kazakhstan), east Russia (Ananino and Perm) and south Russia (Kuban), and after they became known in the 1920s were rightly recognized as related to Scythian art. However, older, pre-Scythian strains are also present in Ordos art. In fact, it seems that the Bronze Age sequence established for Siberia is fully answered by the Ordos bronze material so far known, whereas correspondences with Shang art appear to be limited to the types mentioned above. These types belong, in Siberia, in the periods called Andronovo (*c.* 1700–1300 B.C.) and Karasuk (*c.* 1300–1000 B.C.). It is the influence of these cultures, including early Ordos, which in the author's opinion accounts also for the lesser bronze finds in several Kansu and Jehol painted pottery sites.

The Karasuk phase is archaeologically important in that it offers early examples of what is known as the Eurasian animal style. This culture has been explained as the result of an amalgamation with Mongoloid elements which, absent in the older Andronovo population, were traced in the skeletal remains of the Minusinsk area. Even so, most of the Karasuk inventory, whether metal tools or pottery, is linked with Andronovo, and the animal sculptural adornments of daggers and knives (which might be taken as testimony of influences from Anyang or the Shang cultural sphere at large) agree so well with older Siberian animal sculpture in stone, antler and bone that there is little need to look to China for their origin; particularly since the comparable specimens from Anyang appear to be novelties with no background of native traditions. A grave disadvantage in an attempt at disentangling these Bronze Age Chino-Siberian relations is the lack of scholarly excavations in the Ordos region; no ancient settlements, burials, skeletal materials, pottery or other tomb furniture were known in the mid-1950s. Evidence, therefore, rests with the stray finds of metal tools and chronology. Taking this latter fully into account, it can only be assumed that metallurgy came to China from the northwest, ultimate filiations with Mesopotamia notwithstanding.

Perhaps no other single factor so aptly illustrates the degree of obscurity prevailing in regard to the pre-Anyang period (before 1300 B.C.) as does the Chinese script. Appearing in the archaic but essentially developed system of the oracle inscriptions on tortoise shells and animal bones found in Hsiao-t'un, one of the Anyang sites, this script, an eminent achievement of Chinese civilization, undoubtedly presupposes some span of time prior to Anyang for its evolution. Yet not the faintest trace of any pictographic writing before Anyang has been discovered. It is justifiable, therefore, to conceive of the creation of the Chinese script some time during the obscure two centuries or so before Anyang, a creation which save perhaps for the basic idea of writing was entirely indigenous.

HISTORY

EARLY PERIOD

Introduction; The Influence of Physical Environment.—Throughout its course the history of China has been profoundly affected by physical environment. In the first place, what is known as China proper is singularly fitted for a large and civilized population. Fertile valleys, the loess soil, great alluvial plains a fairly large supply of minerals, a favourable climate and a rainfall which is usually adequate combine to make the region a natural seat for powerful and highly cultured peoples. In the second place, the mountains and rivers within China proper offer no insuperable obstacles to the union of the region under one rule. This is especially true of the part of China embracing the Yangtze valley east of the gorges and the valleys of the Hwang, the Hwai and the Pei (North) rivers. China is fairly easily welded into an empire.

On the other hand, these internal barriers, especially those in the west and southwest, are sufficiently marked to stimulate a strong provincial feeling and dialectal differences. Not infrequently—often for centuries—they have permitted political division. In the third place, the great plateaus, deserts and mountains by which China proper is surrounded have been sources of periodic invasions. The sturdy dwellers in these relatively inhospitable wastes naturally looked with covetous eyes upon the fertile and wealthy plains to the south and east. The necessity of defense against them was constant with every government of China; hence the Great Wall; hence, too, the attempt to control them by the conquest of their homes—Tibet, Sinkiang, Mongolia and Manchuria; hence, too, the periodic infusion of new blood and the highly mixed character of the present Chinese population. In the fourth place, these land barriers, together with the ocean until the 19th century prevented close, continuous contacts with other seats of culture—India, Persia, Mesopotamia, the Mediterranean and Europe. Many contributions have come from without, notably Buddhism. Yet, while absorbing foreign elements, the civilization that developed in China retained a distinctive character partly because of the considerable isolation. The breaking of these barriers by the west was responsible for the stupendous revolution of the 20th century. In the fifth place, the seas played a relatively minor part in shaping Chinese civilization, which at its beginning was continental. Only as coastal regions were absorbed politically, as naval technology developed and as centres of civilization grew in Korea, Japan and southeastern Asia did maritime commerce become increasingly important. Extensive migration by sea was limited to the past several centuries. Geographical environment, in short, encouraged the Chinese to become a numerous, highly civilized, fairly well-unified though mixed people, isolated and nearly self-contained.

Origins.—The origins of the Chinese people and their civilization are still undetermined. It need not be assumed, indeed it is unlikely, that the people were of one original stock or that the civilization spread from one centre either within or outside the modern boundaries. It appears more likely that many different ethnic groups and many separate centres of primitive culture gradually merged and mingled to produce the civilization that has been continuously unfolding and spreading over this continental region. Archaeology revealed the existence of Neolithic culture in numerous sites in China. This culture bore fundamental resemblances to the Neolithic in many parts of the Eurasian continent but also had some distinctive features. In different parts of China, moreover, there were from early times regional variations. There was apparently a continuity of population from Neolithic times into the historic period, and there

are some evidences of cultural continuity as well.

The sources of information available allow no simple conclusion about the complex question of the connection between the civilization of China and other ancient centres to the west.

The oldest Chinese historical literature, that in the *Shu Ching* (*Canon of History*)—parts of it the so-called "ancient text," a late forgery—and the earliest extant collection of ancient songs and poems, the *Shih Ching* (*Canon of Odes*), cannot be depended upon for information earlier than the 1st millennium B.C., and much of that is by no means uncontested. The earliest documents in even these books show a civilization which is already far removed from primitive conditions and contain no certain proof of either a native or a foreign origin for the Chinese. Archaeology has only begun to help. Researches in central Asia disclosed extremely ancient seats of culture east of the Caspian and suggested the possibility of migrations from what is now Sinkiang and Mongolia and possibly from farther west, and also the possibility of very early transmission of some art forms from western Asia and southeastern Europe. Remains of a Neolithic culture in Honan and elsewhere, with vessels and implements resembling those in use by the Chinese in historic times, were brought to light. The excavations at Anyang in Honan told much of the second traditional dynasty, the Shang, but gave evidence of nothing but a native origin for the rich bronze culture and its highly sophisticated writing. All that can be said with certainty is that clear glimpses of what can be called with assurance Chinese culture are caught first in the present area of Honan, Shantung and Shensi, that at the time from which we have remains it was already old, and that it and the people who possessed it were probably the result of several strains from different parts of Asia. Much and perhaps all of Chinese culture may have developed in China itself.

Mythical and Legendary Period.—The Chinese, like other peoples, have accounts which attempt to trace their history to its beginnings. Chinese myths speak of gods and demigods in what became Kansu and Shensi, of a first man, P'an Ku, who was endowed with supernatural powers and was the first ruler of the world and of several series of emperors who were followed by Sui Jén, the "Fire Producer," who learned how to kindle fire by watching a bird produce sparks by pecking at a tree. The legendary Fu Hsi is thought of as having introduced matrimony, substituting the patriarchate for the matriarchate, as the inventor of the *pa kua*, or trigrams, much used in divination, as having taught his people hunting, fishing and the care of flocks, as the originator of musical instruments, as having substituted a kind of hieroglyphs for a system of knot writing previously used, and having arranged a calendar. Fu Hsi is supposed to have been followed by Shên Nung, to whom is ascribed the introduction of agricultural implements and the tilling of the fields and the discovery of the medicinal properties of plants.

Shen Nung in turn was succeeded by Huang Ti, or the Yellow Emperor, who is held to have extended the boundaries of the empire, to have regulated the calendar, to have been the first builder of houses and cities, to have organized a board of historiographers and to have improved commerce. His consort is said to have invented the manufacture of silk.

Various dates are assigned to these last three rulers, but most chronologies agree in placing them somewhere in the 3rd millennium B.C. Whether these emperors ever existed is uncertain. At best they are but legendary figures.

Huang Ti is supposed to have been followed by four other rulers, and these in turn by the famous rulers Yao, Shun and Yü. These three are the first monarchs mentioned in the *Shu Ching* and were regarded by Confucius as models. Dates and details are still extremely uncertain, for most of those usually given are of late origin. Even the historicity of the three is to be viewed with decided doubt. Yü is held to have dealt successfully with the problem of draining away the waters of a great flood and to have founded the first dynasty, the Hsia (to which are ascribed the doubtful dates of 2205–1765 B.C. and whose very existence is questioned). It is said to have come to a close with the reign of an intolerable tyrant, Chieh Kuei, and to have been overthrown by T'ang, who in turn founded another dynasty, the Shang or Yin. The Shang dynasty is said by some to have lasted from 1765 to 1122 B.C., by others from 1523 to 1027 B.C.

Beginnings of History; The Shang Dynasty.—The existence of the Shang, however, has been amply demonstrated by modern archaeology. What have been some of the most brilliant and startling of relatively recent archaeological discoveries revealed the Shang to have had bronze utensils of unusual beauty and skill of construction and writing out of which came the present Chinese system. There was an elaborate system of divination by heating bones and tortoise shells and interpreting the cracks which came with cooling. There were chariots and horses and domesticated cattle, pigs, sheep, dogs and chickens. There were buildings of some size. The cowrie, a shell, was used for money. Stone was sculptured. The family was important and was reinforced by ancestor worship (at least in the royal house). Various spirits and deities were revered. The Shang dynasty, like its predecessor, is said to have been brought to its end by the misdeeds of its last ruler, Chou Hsin.

The Chou Dynasty.—Condign punishment was inflicted on Chou Hsin by the rulers of the principality of Chou. Chou was on the western frontier, a buffer against the constant pressure of invaders who would seize the fertile plains. It may itself have been founded by a fresh wave of immigrants from the northwest closely related to those controlled by the Shang.

One of the rulers of Chou, Wên Wang, who, so the records claim, had devoted himself to governing well his little state, protested against the cruelties of Chou Hsin and was incarcerated for his pains. While in prison he is said to have produced the *I Ching*, or *Canon of Changes*, a volume based upon the trigrams and later viewed with great veneration and incorporated into the Confucian canon. The book is, however, undoubtedly of much later origin. Wên Wang's son, Wu Wang, eventually obtained his father's release and then, after his father's death, with the aid of a coalition of princes, overthrew Chou Hsin and established himself as the first monarch of the Chou dynasty. Wu Wang was greatly aided by his distinguished brother, Chou Kung, or the duke of Chou, whose regency during the minority of the second emperor of the dynasty is held by orthodox historians to have been ideal. The Chou dynasty lasted until 249 B.C. and so had a longer life than any other which has held the throne of China.

The nearly nine centuries of the Chou dynasty witnessed many important developments. First of all, the area of the realm was greatly extended. Expansion carried the Chinese and their culture to the sea on the east, to the Yangtze river on the south and to the eastern borders of Szechwan. The "barbarians" in these regions appear to have adopted Chinese culture and to have been assimilated by the conquerors. This expansion was for the most part not the result of any leadership provided by the imperial house. After the death of its founders, the dynasty produced few monarchs of outstanding ability. One, Mu Wang, is reported to have been a great traveller and to have extended his journeys to the mysterious "Royal Lady of the West" (Hsi Wang Mu). Most of the emperors, however, were distinctly mediocre, and some are remembered chiefly for their folly. The spread of Chinese power was the result chiefly of the energies of adventurers and the activities of heads of subordinate principalities.

The realm, as it expanded and as the quality of the Chou declined, tended to break up into semi-independent states. These made war on one another, concluded peace and developed the rudiments of international law, with scant attention to the authority of the imperial house. The power of the central administration more and more fell into abeyance, until, finally, the result was a condition which in many respects resembled European feudalism.

The Chou dynasty is memorable for a marked development in culture. Agriculture was highly developed through irrigation and the regular division of lands, some of the metals were in use, literature had come into existence, including poetry, history and state archives, schools were to be found, and industry and commerce had sprung up. As in the Shang, there were bronze implements and utensils, although not so skilfully cast as under the

earlier dynasty. Religion was highly developed, with divination, the worship of ancestors and of spirits of hills, rivers, stars and other natural objects, and adoration of a supreme being variously called Shang Ti and T'ien. Much emphasis was placed on ceremonies and ritual, both in religion and in official intercourse, and a keen sense of ethical values had developed, reinforced by the belief that the supreme being was on the side of righteousness and hated iniquity. Then, as in modern times, the family was the dominant social unit. Knowledge of the period is not sufficiently complete to enable us to trace all the growth in culture which occurred, nor is it known how much this was attributable to influences from peoples outside the expanding frontier.

Some developments, however, are known, chief among them being the expansion of thought and the rise of schools of philosophy. Most of the thinkers seem to have been associated with the government. Certainly the problem which chiefly engaged their attention was the welfare of society. Cosmogony did not greatly concern them. To their minds, however, the disorder which attended the breakdown of the central government and the division of the country into warring states dominated by autocratic rulers was of great moment, and they sought to build a new order which would bring happiness to all. More is said elsewhere of the teachings of the Chou philosophers. It is sufficient to state here that Confucius (551–479 B.C.) sought to save society by a return to the way of the ancients. This he believed to involve an emphasis upon ethics—especially upon moral education—and upon ceremonies. By the leadership and example of the educated, and by the careful regulation of society by the ceremonies which had come down from the past, he would bring in a golden age.

In his train and approving his solution came others, chief among them Mencius (372 or 385–289 B.C.), who stressed the essential goodness of human nature and the right of subjects to revolt against a persistently unjust ruler. Another school, Taoism, had as its foundation classic the *Tao Tê Ching* and attributed this to one Lao Tzŭ (Lao-tse), who is said to have been an older contemporary of Confucius. The authorship and the dates of Lao Tzŭ are highly doubtful. The solution for the woes of mankind offered by the *Tao Tê Ching* was conformity to the way of the universe. The way of the universe was believed to be the absence of all man-made restraints and freedom from elaborate regulations and from what passed for civilization. This solution was, obviously, quite different from that advocated by Confucius, and members of the two schools engaged in frequent controversy. Belonging to the school of the *Tao Tê Ching*—Taoism—were many other thinkers, notably Chuang Tzŭ (*c.* 369–286 B.C.). A book bearing his name is a witty exposition of the Taoist view that happiness may be achieved only by the free development of man's nature and that the best way of governing is through non-government.

Mo Ti, who lived between the times of Confucius and Mencius and who was the precursor of two schools which for several centuries were to have great vogue but were eventually to disappear, taught that institutions should be submitted to the pragmatic test—were they of benefit to society? He was deeply religious, believed that T'ien (Heaven) loved men and that all men should love one another. It was his doctrine of universal love as the basis of ethics which brought against him the vigour of Mencius' dialectic. Yang Chu, a contemporary of Mencius, declined to trouble himself about society, maintained that death ended all and held that each man should live for himself and for his own pleasure. Hsün Tzŭ, born in 340 B.C., denied immortality and the existence of spirits and held that man, although bad by nature, could be improved by regulations and ceremonies. The legalists, as their name indicates, wished autocratic rule through the enforcement of law rather than the Confucian influence of moral example.

These and others show how diverse and vigorous was the thought of the age. Never again was Chinese philosophy to be so creative and so untrammelled by the past. Systems then begun were to persist until modern times.

The Ch'in Dynasty.—The philosophers, for all their theories, were unable to prevent the progressive disintegration of the realm. Under the last Chou emperors internal strife so increased that the final 250 years of the dynasty are dubbed Chan Kuo, "the Contending States." Individualism was the order of the day. In the general anarchy the Chou dynasty as last disappeared. The end of the Chou and the union into one empire of the large territory over which the Chinese people and culture had now spread were achieved by the rulers of the state of Ch'in. Ch'in, on the northwestern frontier, like the state of Chou before Wu Wang, had been a buffer against the barbarians. Its princes at last conquered their rivals and took the emblems of imperial power from the weaklings of the Chou line. The last of the Chou was deposed in 249 B.C. The welding of the new domains of the Ch'in into a unified state was the work of the Ch'in ruler who ascended the throne in 246 B.C. and who styled himself Shih Huang Ti, the "First Emperor." Assisted and perhaps inspired and directed by his minister, Li Ssŭ, and utilizing the principles of the legalists, Ch'in Shih Huang Ti abolished the political system of the Chou, with its many petty states and hereditary princes, and divided the country into 36 provinces, over each of which he set officials appointed by and directly responsible to himself. As an emblem and centre of his power he built a capital near the present Sian (Hsi-an, Shensi province). He introduced a uniform system of laws, weights and measures, thus aiding both unity and commerce. He extended the boundaries of the empire, carrying his arms into what became Fukien, Kwangtung and Kwangsi and against the barbarians—the Hsiung Nu—on the northern and western frontiers. To defend his borders on the side from which they were most frequently attacked, he constructed the Great Wall. This had probably already existed in part, but he completed and strengthened it. Later orthodox scholars held his name in reproach for one of the signal acts of his reign, the "burning of the books." What motives lay behind this deed we do not know; he probably believed that the scholars who were advocating political philosophies contrary to the legalist school on which he was building his regime were enemies of the new order he was trying to establish. Whatever his motives, he had the existing literature collected and burned, exempting only copies he preserved in the imperial library and books dealing with divination, pharmacy, medicine, agriculture and arboriculture. He commanded scholars to desist from discussing the past. The old order did not expire without a struggle. Ch'in Shih Huang Ti died in 210 B.C., and almost as soon as his strong hand was removed the structure he had erected collapsed. Insurrection broke out, the feeble "Second Emperor" was murdered (207 B.C.), and military chieftains set to fighting for the throne.

The Han Dynasty.—Out of the renewed civil strife one of the contestants, Liu Pang, shortly emerged victorious and founded the Han dynasty (202 B.C.—Liu Pang counted his reign as having begun in 206 B.C.). The effort of Ch'in Shih Huang Ti had not been in vain. The "feudalism" of the last years of the Chou had been so badly shattered that Liu Pang found it possible to unite the country quickly. At the beginning the Han attempted to rule the empire by a system which was a combination of that instituted by the Ch'in and of "feudalism." Members of the emperor's family were placed over the main divisions of the realm. This compromise carried with it the seeds of the old pernicious particularism, however, and after about a century the principle of hereditary local power was curtailed and the practice was adopted of governing through a civil service recruited on the basis of worth. Worth was to be discovered in part by means of examinations. Confucianism in a modified form rather than legalism became orthodox. Greatly enlarged by later dynasties, the practice of recruiting officials by means of examinations was to be a means of holding the country together. It was one of the most successful political devices ever invented.

With the consolidation of China went foreign conquests. The major ones date from the long and brilliant reign of Wu Ti (140–87 B.C.). The Han arms were directed chiefly against the barbarians on the northwest, especially the Hsiung Nu. Alliances against this common foe were made with central Asiatic peoples. To effect the alliances Chang Ch'ien was sent to the west and went as far as Bactria. The power of the Hsiung Nu was broken

and the Han rule was extended into what is now Sinkiang. In the dry air of the far northwest remains of fortresses and walls built by the Han to guard the frontier have survived to our own day. The Han also carried their arms south of the Yangtze as far as Tongking and to the northeast into Korea.

With unity, increased prosperity and conquests came foreign trade. The caravan routes to the west had been made safe by the defeat of the Hsiung Nu, and products from central Asia and even from the outposts of the Hellenistic world reached China, and Chinese goods were sent in exchange.

Literature and art revived. The first emperor of the Han declined to remove the prohibition of Ch'in Shih Huang Ti against the ancient books. The ban was lifted by his successor, however; documents which had escaped the holocaust were brought out from their hiding places, and scholars devoted themselves to restoring the texts and writing commentaries on them. The Han could not boast of as much original philosophical thought as could the Chou: it may be that the emphasis placed by the state upon the study of the classics of the Confucian school discouraged originality. Taoism was espoused by many in high position, but it degenerated more and more into magic and the search for the elixir of life and for means of transmuting the baser metals into gold. Historiography was greatly developed, however, the outstanding work being the monumental *Historian's Records* (*Shih Chi*) of Ssu-ma Ch'ien. Poetry, too, revived. In art the Han period showed some new forms, several of them possibly influenced by contacts with central Asia and the west.

The Han rule suffered a temporary interruption when, in the 1st century of the Christian era, Wang Mang, one of the most interesting social and economic innovators in Chinese history, set aside an infant emperor (A.D. 8) and for a few years ruled as the emperor of the Hsin dynasty. Princes of the Han, however, defeated and killed him, and in A.D. 23 restored the dynasty. The capital was now moved from Ch'ang-an (Sian) in the later Shensi province to Loyang in the later Honan province. The dynasty after this interruption is known as the Later or—because of the change of capital—Eastern Han, as distinguished from the Earlier or Western Han.

The Later Han renewed the conquests in the west, and under Gen. Pan Ch'ao the Chinese became masters of parts of central Asia. A Chinese embassy reached the Persian gulf. Partly because of the control by the Han of the caravan routes to central Asia and partly because of the possession of Tongking and the south, commerce was maintained with the Roman orient—known to the Chinese as Ta Ts'in—both by land and by sea. Chinese silks were carried to the Mediterranean world, and products from central Asia and the Hellenistic world were brought to China.

Through these contacts with the west came Buddhism. The story which attributes its introduction to a dream of the Emperor Ming is a pious fabrication of a later age, but that it entered China under the Han is certain. The Later Han continued the patronage of letters, and especially of the Confucian school, which had been accorded by the Earlier Han. Literature flourished and was furthered by the invention of paper (*c.* A.D. 105).

The annals of the Han dynasty, like those of both its predecessors and successors, are punctuated by rebellions and intrigues. As the imperial line became weak, these succeeded in bringing it to an end, and a period of disunion followed which was to last for nearly four centuries. So thoroughly had the Han emperors welded China together, however, that cultural unity and the vision of a single empire were never lost, and to this day the Chinese call themselves the "Sons of Han." Under the Ch'in and the Han China had for the first time become a great state.

Three and One-Half Centuries of Disunion (the "Three Kingdoms").—The Later Han technically came to an end in 220. It was succeeded by three states—the "Three Kingdoms"—Wei in the north, ruled by the successors of Ts'ao Ts'ao, minister and betrayer of the last of the Han; Wu in the central and lower part of the Yangtze valley, with its capital at Nanking; and Shu, in Szechwan, whose monarchs, of the house of Han, claimed title to the entire empire and which, for its Han connection, is known as the Minor or Shu Han. The period was one of almost constant war and is famed for the exploits of its chief figures, popularized for later ages by the stage and the historical novel *San Kuo Chih Yen I.* Liu Pei, first prince of the Minor Han, was aided by Chang Fei and Kuan Yü, the latter of whom was later deified as the god of war, Kuan Ti. He was also assisted by Chu-ko Liang, who was noted as a strategist and as the inventor of war machines. The fortunes of war varied, but not one of the three kingdoms was able long to conquer the other two.

To domestic dissension was being added foreign invasion. Peoples from the north and west—Mongols, Hsiung Nu and Turks—took advantage of the internal weakness of the fertile lands to the east and south and seized much of the territory north of the Yangtze. Many ephemeral states and dynasties followed, the invaders striving to establish themselves in the north and the Chinese, from the south, endeavouring to beat them back. The period is accordingly known as the epoch of the northern and southern dynasties. The most prominent among many dynasties of the period were the Eastern Chin (A.D. 317–420), with its capital at Nanking; the Sung (420–479, called Liu Sung to distinguish it from the later and more famous Sung dynasty), also with its capital at Nanking; the Northern or Yüan Wei (386–535) of the Toba Tatars, with its capital at the modern Tatung in Chahar, and at its end dividing into the Western and the Eastern Wei, followed by the Northern Ch'i and the Northern Chou. In the south ruled the Ch'en.

The period was one of transition in civilization. Many of the invaders adopted Chinese culture, but they could not but modify it. Buddhism now achieved popularity, perhaps in part because with the breakdown of central authority the Confucian school could not offer the resistance that it could under the Han. Many of the monarchs espoused the foreign cult, missionaries came in numbers, and Chinese, the best known of whom was Fa-hsien, went on pilgrimages to the sacred sites in India and returned with Buddhist scriptures.

By the time the empire was once more united, Buddhism had become an integral part of its life and was having profound effects upon other religions, popular thought, literature and art. The Buddhist sculptures of the period are noteworthy. During the last years of disunion and during the first century or two of the union which followed, Buddhism was more prosperous than it was ever again to be in China. The many new sects which arose within it testified to its vigour. Taoism, too, under the stimulus of Buddhism, developed as an organized church and became a great popular religion.

Though it was a period of disunion and turmoil, the 3rd to 6th centuries showed great increases in knowledge of medicine, mathematics, astronomy, botany and chemistry. Through foreign missionaries and returning pilgrims, merchants and embassies, the Chinese became much better informed about the outside world. Sea connections and commerce between China and southern Asia increased. The lower Yangtze region became more highly developed economically and culturally.

The Sui and the T'ang.—After the long period of division, union was once more achieved, first under the Sui dynasty (A.D. 589–618) and then under the T'ang (618–906). Under the second emperor of the T'ang, T'ai Tsung (627–649), China became more powerful than it had been since the Han and was for a time the strongest and largest empire on earth. Under the T'ang Chinese arms were carried again into Korea, into Turkistan, across the Pamirs to northwest India and into Tibet. To China, and especially to the T'ang court at Ch'ang-an, the later Sian, journeyed peoples of many lands and faiths. Moslems, Nestorians and followers of Manichaeism came, and Persians sought aid against the Moslem Arab wave of invasion. The Nestorians had missionaries and churches in China and, apparently, a fairly extensive literature. Japanese carried home ideas which were to continue the revolution in the life of their nation that contact with China immediately before the T'ang had begun. Chinese Buddhist pilgrims also continued to visit India.

Under the T'ang the bureaucracy and its accompanying civil service examinations were further developed, and the latter were

capped by the foundation of the Han Lin academy, in later years charged with the compilation of histories, the drafting of decrees and other literary labours.

In the prosperous and peaceful T'ang period, painting reached new heights and China's most famous poets wrote. Among the latter the most distinguished were the realistic Tu Fu and the Bohemian and attractive Li Po. From the T'ang dynasty dates the earliest-known printing, and paper money made its tentative appearance.

Of the many rulers of the T'ang little need be said here. Besides T'ai Tsung the best remembered was probably Hsüan Tsung (Ming Huang) (reigned 712–756). Under him lived the greatest poets and painters. In him the dynasty reached its apex, and toward the close of his reign a disastrous rebellion broke out which marked the beginning of the dynasty's decline. After him invasions and rebellions decimated the population, and in 907 the dynasty was brought to an end.

The Five Dynasties (907–960).—Following the T'ang various aspirants for imperial honours fought for the throne, and in quick succession there followed five ephemeral dynasties, known as the Later Liang, the Later T'ang, the Later Chin, the Later Han and the Later Chou. Their assumption of famous names did not prevent the early demise of each, and in 960 the last gave way to the Sung dynasty.

The Sung Dynasty (960–1279).—The Sung dynasty, founded by Chao K'uang-yin, began auspiciously. Most of the country was reduced to submission, the capital was placed at Kai-feng, near the site of the glories of some earlier dynasties, and under the first few rulers the civil service was so developed and improved that it became a model for later times.

This did not prevent the former, however, from arrogating ever more authority to the throne. Before long evil days came. An attempt to conquer the K'itan, a people of Mongol tongue who ruled the Liaotung peninsula, proved unsuccessful, and the K'itan occupied portions of the empire adjoining their domains and were prevented from further depredations only by the payment of tribute. On the northwest another kingdom, that of Hsi Hsia, threatened the frontiers and fought both the Sung and the K'itan. The Sung called to their assistance the Chin ("Golden") Tatars, but after expelling the K'itan the Chin made themselves masters of the territory north of the Yangtze and the Sung were constrained to move their capital to Hangchow. In the wake of the Chin came the Mongols. The great Mongol general Temuchin, or Jenghiz Khan (*q.v.*), invaded China early in the 13th century. By 1223 he had possession of most of the country north of the Hwang-ho, having defeated the Chin. Before his death (1227) Jenghiz had made further inroads on the Chin and had defeated the Hsi Hsia. Jenghiz' successor, Ogdai, formed an alliance with the Sung, and the two made an end of the Chin. The allies then fell out, and the Mongols under Ogdai, Mangu and Kublai pressed south, until, after the last of the Sung monarchs had in despair cast himself into the sea, Kublai in 1279 became emperor of all China.

The military misfortunes of the Sung did not prevent the dynasty from synchronizing with one of the great creative periods of Chinese culture. Painting, under the influence of Buddhism and Taoism, reached a very high point. Philosophical schools contended with each other, and one, culminating in Chu Hsi (1130–1200), gave Confucianism the form which until the 20th century was to be regarded as orthodox. Notable histories were written, among them that of Ssŭ-ma Kuang. An interesting experiment in economic and political reorganization was made under the leadership of Wang An-shih (1021–86). Wang An-shih was a brilliant and thoroughgoing radical. He sought to change the existing educational system and make it of more practical use. He issued original commentaries on the classics, reading new meanings into these ancient documents. For 18 years, as prime minister, he inaugurated and superintended what resembled the later European socialism. His object was to make the state better fitted to cope with its foreign enemies. To this end he would have the government take over the entire management of commerce, redivide the land, regulate prices, make loans to farmers at moderate rates of interest and place more of the burden of taxation on the rich. He also put upon every family the burden of military defense and appointed a commission to fix a national budget. Wang inevitably had many enemies and critics, one of the chief being Ssŭ-ma Kuang. These eventually forced his retirement and restored the *status quo*.

The Mongol Dynasty (1260–1368).—The Mongol or, as it was officially known, the Yüan dynasty was not of long duration. The reign of Kublai was brilliant. From his capital at Khanbaliq, or Cambaluc, on approximately the site of the modern Peking, he ruled not only over China but over most of the vast Mongol empire, with its western frontiers in Mesopotamia and Europe. Expeditions were sent into Champa, Annam, Burma and Java and against Japan. Under him, however, Mongol power reached its climax. The invasions to the south ended in a somewhat inglorious retirement, the attempt on Java was unsuccessful, and the armadas against Japan met with overwhelming disaster. The Mongols ruled China largely as conquerors and brought in many foreign troops and hordes of foreign officials.

After Kublai the ability of the monarchs rapidly declined, rebellions arose, the Mongols were expelled, and in 1368 the most successful of their opponents, a former Buddhist monk, Chu Yüan-chang, became the first emperor of a new dynasty, the Ming.

The Yüan dynasty, brief though it was, was not without notable developments. The Grand canal was completed, and drama and the novel first became important. The safety of the trans-Asiatic trade routes under Mongol rule and the Mongol method of government brought many foreigners into China. Nestorian Christianity had survived on the edges of the empire since the T'ang and now reappeared in China. Moslems entered in fairly large numbers, and even Armenians were to be found. Now for the first time western Europeans made their way to China.

The eastward expansion of Europe in the crusades and Italian commerce, and the burst of missionary enthusiasm through the Franciscan and Dominican orders, brought Europeans to the western fringes of the Mongol empire. It was natural that European merchants and missionaries should make their way to China —or Cathay, as they called it. Most notable among the merchants were the Venetians Nicolo and Maffeo Polo, and the son of Nicolo, Marco. Marco Polo was for years in the service of Kublai and, returning to Venice, wrote the account of his travels which has made him famous. Friars were sent as envoys to the Mongol rulers in central Asia, but so far as is known the first to reach China was the Franciscan Giovanni di Monte Corvino, who arrived at Cambaluc in 1294 and there, in the ensuing three decades or more, built up a Christian community of several thousands. When news of his success reached Europe he was created archbishop of Cambaluc, and reinforcements were sent him.

In the course of the next few years numbers of other missionaries arrived, notably a papal legate, Giovanni de' Marignolli. With the collapse of Mongol rule, however, the trade routes became unsafe and an antiforeign reaction set in; Europeans, both merchants and missionaries, disappeared from China, and the Catholic Nestorian communities passed out of existence.

The Ming Dynasty (1368–1644).—This new and purely Chinese dynasty was not noteworthy for its brilliance. Under it, however, the empire was fairly prosperous. The first emperor, Chu Yüan-chang, better known by his reign title, Hung Wu, unified the country and established his capital at Nanking. His fourth son, the third emperor, commonly known by his reign title, Yung Lo, came to the throne through a sea of blood but proved an able ruler. He was a great builder: he established his seat at Peking, and the palaces and temples which through succeeding centuries made the city architecturally one of the outstanding capitals of the world were largely his work. He was a patron of literature. He sent expeditions to the south and southeast as far as Java and Ceylon. One of the princes of Ceylon was brought captive to China, and for years tribute came from the island. Under a succeeding monarch an expedition was sent by sea as far as the Persian gulf. Under the Ming emperors, moreover, Korea was invaded, Annam for a time became subject to China, and frequent wars with the Mongols usually kept those

ancient enemies at bay. As time passed, the decline which was the inevitable fate of dynasties brought weakness to the empire. The Japanese invaded Korea, and for decades Japanese pirates ravaged the coasts.

The Ming period brought a restoration of Chinese culture after a long period of foreign domination. All forms of intellectual and artistic life flourished; there was a growth of academies, libraries and book printing. In philosophy the neo-Confucian school of Chu Hsi was dominant, but Wang Yang-ming (1472–1529) founded an influential school of thought which maintained that reality and truth lie in the mind and that knowledge is achieved intuitively. Scholars were active, studying and reinterpreting the Confucian canon, writing treatises on philology and geography or monographs on arts and sciences, preparing dictionaries and an illustrated encyclopaedia. In literature the novel developed into an important new genre. Architecture, landscape painting and ceramics showed vitality.

An important development was the introduction of new crops and the spread of their use. Cotton, introduced in the 13th century, was now widely cultivated; cotton cloth began to be worn throughout the empire. New world plants such as maize, or Indian corn, sweet potatoes and peanuts enriched the diet and allowed the profitable cultivation of unused land. Tobacco entered toward the end of the dynasty. These crops and others adopted during the 17th century helped make possible the large growth in population during the next dynasty.

The Ming period was made memorable by the renewed coming of Europeans. The European voyages and conquests of the 16th century brought the Portuguese to India, Malacca, China and Japan and the Spaniards to the Philippines. The first Portuguese reached China about 1514 and within a few years had established themselves at several ports. The first comers were so truculent, however, that before long they were driven out or massacred. For a brief time the Portuguese traded from the island of Shang-ch'uan, south of Canton, but shortly afterward were permitted to form a settlement at Macao—the exact date is uncertain, but was probably between 1552 and 1560—and retained that as their base. Missionaries came. St. Francis Xavier died on Shang-ch'uan (St. John Island) in 1552 while engaged in a vain attempt to enter the empire. His fellow Jesuits renewed the effort and before the close of the century had established themselves in several cities in the interior. The ablest of their number was Matteo Ricci (1552–1610), an Italian who arrived in China in 1582 and in 1601 succeeded in effecting a residence in Peking. Ricci and his associates commended themselves to the scholar-official class by their knowledge of science, especially of mathematics and astronomy, and were placed in charge of the government's bureau of astronomy in Peking.

MODERN PERIOD

The Manchus.—The weakening Ming dynasty was overthrown by invaders from the northeast, the Manchus. The Manchus had been welded into a formidable force by Nurhachu (1559–1626) and before his death had aspired to the empire. Their opportunity came when, in 1644, a rebel, Li Tzŭ-ch'eng, made himself master of Peking and the Ming emperor committed suicide. A Ming general, Wu San-kuei, joined forces with the Manchus to oust Li, and a Manchu prince was placed on the throne. Ming claimants did not tamely submit, and it was not until 1662 that the last of them, driven, after stubborn resistance, to the Burmese borders of Yünnan, came to his end. Somewhat later, the successors of Koxinga, who had been implacable toward the Manchus and had harried the south coast and had ruled Formosa, were eliminated.

For a century and a half the Manchu (or the Ch'ing dynasty, 1644–1911) provided the throne with able rulers. The monarchs whose reigns were named K'ang Hsi (1662–1722) and, after the brief interlude of Yung Chêng (1723–35), Ch'ien Lung (1736–96) had, from the standpoint of foreign conquests and domestic prosperity, as brilliant careers as the empire had known.

The Manchus ruled as conquerors and maintained permanent garrisons in strategic centres throughout the country, but they adopted Chinese culture, perpetuated the time-honoured administrative machinery and laws, associated Chinese with themselves in the highest boards at Peking and opened to them all the provincial offices. They guarded against revolt by forbidding a Chinese to hold office in his native province, by frequently shifting officials and by dividing the administrative responsibility for each province among several officers who could serve as checks on one another. They vigorously put down revolts, notably that of Wu San-kuei, to whose aid they largely owed the throne. They ruled Manchuria and conquered Mongolia; under K'ang Hsi they added Tibet and Formosa to their possessions and, under Ch'ien Lung, Ili and Turkistan. Ch'ien Lung's armies penetrated Burma, Nepal and Annam, and Korea paid tribute.

Never had the empire covered so much territory, and never had it been so populous. With the reign of Ch'ien Lung the dynasty passed its zenith, and after it the quality of the ruling house declined. In the later years of Ch'ien Lung and under Chia Ch'ing (1796–1820), Tao Kuang (1821–50), Hsien Fêng (1851–61) and T'ung Chih (1862–75) numerous rebellions kept part or all of the country in turmoil.

In culture, the China of the Manchus was largely a continuation of that of the Ming. Ceramics were elaborated, but painting did not equal that of the Sung. Scholarship flourished under imperial patronage with the compilation of vast encyclopaedias, dictionaries, geographies and other compendiums of knowledge. Historical and textual criticism reached its maturity in the School of Han Learning, a movement which undertook to restudy the authenticity of all ancient works and to strip away the accretions of later centuries. This movement challenged the very basis of Sung neo-Confucianism. But a return to orthodoxy, fostered by the emperor Ch'ien Lung, marked the latter part of the dynasty.

Pressure by Europeans to gain a foothold in China became an increasingly serious problem. Catholic missionaries continued to come. To the Jesuits were added in the 17th century Franciscans, Dominicans and Augustinians from the Philippines, Franciscans from Italy and members of the Société des Missions Étrangères of Paris. In 1692 K'ang Hsi issued what amounted to an edict of toleration, and for a number of years the church prospered greatly. Missionaries and Christian communities were in all provinces, and by 1700 the Catholics in the empire probably numbered more than 300,000. Then came a series of reverses. A prolonged controversy over the question of what Chinese term should be used for God and of what attitude should be taken by Christians toward certain Chinese rites, among them the honours paid to ancestors and to Confucius, divided the foreign staff. When Rome finally spoke, the decision antagonized K'ang Hsi and the Chinese scholar class. Repeated persecutions arose—only in part because of the decision on the rites; in 1773 papal orders dissolved the Society of Jesus, and the Lazarists, in spite of valiant attempts, could not fully take its place. Religious indifference in Europe, the French Revolution and the wars of Napoleon cut off support from home. By 1800 the Catholics in the empire numbered only about 200,000 and were badly demoralized. Between 1600 and 1800, however, Catholic missionaries had helped to acquaint China with European science and religion and, by their writings, had spread in Europe a knowledge of China.

European merchants did not penetrate the empire as did the missionaries, but they continued to come. Although their commerce declined, the Portuguese retained Macao. The French, Dutch and British opened trade with China, and in 1784 came the first ship from the United States, the precursor of many more. By the middle of the 18th century British trade was more important than that of any other occidental people and was the official monopoly of the English East India company. Chinese teas, silks and cottons were in great demand in Europe, and for a time were paid for largely by specie. Eventually, however, the importation of opium, chiefly from India and on British ships, brought a reversal of the balance of trade.

Commerce was carried on under great restrictions. By the close of the 18th century only one port, Canton, was open to merchants from abroad. The Europeans were there confined to a small area—the "factories"—and were ordered to spend the quiet

months in Macao. Business could be conducted only through an officially designated group of Chinese merchants, the Co-hong. The absence of fixed tariff charges, the exactions of venal officials, the unwillingness of the Chinese to permit official intercourse on the basis of equality, the prohibition against a Chinese teaching a foreigner the language, the subjection of the foreigner to Chinese laws and courts were all galling to the westerner.

Russia had little if any better treatment. K'ang Hsi had momentarily checked the Russian advance by the capture of Albazin (1685) and there followed the first treaty to be signed with a European power, that of Nerchinsk (1689), which, with its successor, the treaty of Kyakhta (1727), provided for trade, diplomatic intercourse—in part through a resident Russian mission in Peking—and the extradition of criminals.

Repeated attempts were made to obtain better terms. Portuguese, Dutch and British embassies travelled to Peking, notably those of the British in 1793 and 1816, led respectively by Earl Macartney and Earl Amherst, but to no avail. The Chinese had never been accustomed to dealing with other governments on the basis of equality and regarded all foreign envoys as bearers of tribute.

The First War With Great Britain and the First Group of Foreign Treaties (1839–44).—Such a condition of affairs could not endure. The industrial revolution inaugurated a period of renewed expansion of the occident, and the west desired admission to China to market the products of its factories and to obtain raw materials. This was also the period of the important clipper ship trade between the United States and China.

Pressure first came from Great Britain, the European nation in which the industrial revolution began. On demand from British merchants, the monopoly of the China trade by the English East India company was abolished (1834), and friction between the English and Chinese increased. Lord Napier was appointed the first "superintendent" of British trade in Canton (1834), but Chinese officials looked upon him as merely a head merchant and refused to deal with him as an equal. Lord Napier died while still in this anomalous position, and his successors were unable to effect any improvement in the situation. Armed conflict was all but inevitable. British merchants were insisting upon more privileges than the Chinese were willing to concede, and British and Chinese ideas of international intercourse were fundamentally at variance—the one government being accustomed to a family of equal nations, the other knowing only an empire and subject peoples. Conceptions of law differed, the Chinese, with their emphasis on group responsibility, holding the entire British community liable for the misdemeanour of any of its members and insisting upon a life for a life, even when death had been accidental, and the British contending that upon the individual and not the community should be placed the responsibility for misdeeds.

The conflict came to a head over the question of the importation of opium. This had long been prohibited by the Manchu government, but foreign merchants brought it in ever-increasing quantities and corrupt Chinese and Manchu officials connived at its introduction. After many futile attempts at enforcement, Peking at last took vigorous action and dispatched a special commissioner, Lin Tsêhsü, to stamp out the trade. Lin arrived at Canton in 1839 and promptly set about his task. Foreign merchants were compelled to surrender their stocks of opium for destruction, and pressure was put upon them to give bond not to engage further in the importation of the drug. The British objected to what seemed to them high-handed measures, and in Nov. 1839 hostilities broke out. The Chinese were repeatedly defeated. The war dragged out until 1842, however, for the British contented themselves largely with attacks on centres south of the Yangtze, and their victories alternated with unsuccessful attempts at negotiation. Finally, when Chinkiang—at the intersection of the Yangtze and the Grand canal—was taken and Peking's communications with the south were threatened, the imperial authorities were frightened into concessions, and on Aug. 29, 1842, the treaty of Nanking was signed.

This document provided for the cession of the island of Hong Kong to Great Britain, for the opening to foreign residence and commerce of five ports, Canton, Amoy, Foochow, Ningpo and Shanghai, for liberty to appoint consuls at each port, for communication between British and Chinese officials of the same rank on the basis of equality, for an indemnity to the British, for the abolition of the Co-hong and for a "fair and regular tariff." In 1843 regulations for trade were agreed upon and published, and a supplementary treaty was signed which fixed the tariff rates, assured to the British most-favoured-nation treatment and contained the beginnings of extraterritoriality. Other western nations took advantage of China's defeat. The U.S. sent a commissioner, Caleb Cushing, who negotiated a treaty which conceded, in general, the same commercial privileges to Americans which had been granted to the British and which, among other things, removed U.S. citizens engaged in the opium traffic from the protection of their government, elaborated extraterritoriality and provided for the revision of the treaty at the end of 12 years. In 1844 the French obtained a treaty which had much the same provisions for trade and official intercourse as were guaranteed by the British and U.S. documents. At the instance of the French, imperial edicts were issued providing for the toleration of Catholic Christianity and for the restoration of the church property which had been sequestered in the persecutions of the previous century. In the next few years the Belgians and the Swedes were also given treaties.

The Second Foreign War and the Second Group of Treaties, 1856–60.—The years between 1842 and 1856 were in effect a period of troubled truce. The treaties of 1842 and 1844 were satisfactory neither to foreigners nor to Chinese. From the standpoint of the foreigner they did not grant enough. No provision was made for travel in the interior, for residence in places other than the five open ports or for direct diplomatic intercourse through representatives resident in Peking. The Chinese, on the other hand, believed that the treaties conceded too much, and, since they had been extracted by force, the authorities were not disposed to abide by them any more than they were compelled to do. The Chinese were no further inclined than formerly to treat western "barbarians" as equals. Clashes were frequent. Moreover, the British treaties said nothing about opium, and the traffic in the drug continued, a constant source of friction.

While the Americans, the British and the French were demanding that revision of the treaties which had been promised in the documents of 1844, war between the British and the Chinese broke out over a comparatively minor incident—as is often the case in times of international tension—the violation by the Chinese of a British flag and the arrest of the crew, all Chinese, on a Chinese-owned but British-registered craft, the lorcha "Arrow" (Oct. 8, 1856). The French, then closely associated with the British through the Crimean War, found in the judicial murder of a Roman Catholic missionary, Chapdelaine, in Kwangsi (Feb. 29, 1856), an occasion for joining in the conflict.

The two powers did not at first press the war, for they were just emerging from the struggle in the Crimea and difficulties with Persia in 1856–57, and the Indian mutiny, which blazed out in 1857, engrossed the attention of the British. Late in 1857, however, the British and French took Canton, and in the following year their squadrons went north to Tientsin, thence to threaten Peking into submission. The Taku forts, commanding the entrance to Tientsin, were captured, and to save the capital the Chinese granted the desired treaties. The Russian and U.S. representatives, although not in the war, were on hand to profit by the French and British successes and also obtained treaties. The Russians obtained all the Chinese territory north of the Amur.

The treaties of Tientsin (1858) in general contained the following provisions: (1) the tariff was modified, and by the fixing of a rate for opium the importation of that drug was legalized; (2) the residence in Peking of diplomatic representatives of the powers was promised; (3) foreigners were to be permitted to travel in the interior; (4) the activities of Christian missionaries were sanctioned, and Christians, both foreign and Chinese, were guaranteed freedom in the practice of their faith; (5) foreign merchant vessels were allowed on the Yangtze; (6) several additional ports were opened to foreign residence and trade, includ-

ing Chefoo and Newchwang in the north, one on Hainan, two on Formosa and four on the Yangtze; (7) extraterritoriality was further elaborated; (8) regulations for trade, including the collection of customs, were developed; and (9) indemnities were promised.

When, in 1859, the envoys came to complete the ratification of the treaties and to take up their residence in Peking, they found the road by Tientsin blocked. The Chinese, moreover, proposed the reconsideration of the treaties. The British and French attempted to force their way past the Taku forts and were repulsed. The two powers accordingly renewed the war and in 1860 fought their way through Tientsin to Peking. Peking was captured, the emperor fled to Jehol, and the British, in retaliation for the violation of a flag of truce and the death of some of its bearers, set fire to such of the summer palace as had escaped marauding Chinese troops. The Chinese were now constrained to sign conventions by which they agreed to observe the treaties of 1858, to pay an additional indemnity, to open Tientsin to trade and to permit—more definitely than agreed upon in 1858—the permanent residence of foreign ministers in Peking. The British were ceded the Kowloon promontory opposite Hong Kong, and through the French was obtained treaty sanction for what had been promised earlier, the restoration of confiscated Catholic Church property. In the Chinese, although not in the official (French), text of the French convention was also permission for French missionaries to lease or buy land and build houses in the interior. The Russians, still fishing in troubled waters, obtained a modification of their frontier by which the territory east of the Ussuri was awarded to them. This territory had a long stretch of coast which included the site of Vladivostok.

The treaties of 1842–44 and 1858–60 defined the legal basis on which intercourse between the occident and China was to be conducted. They were later modified in details, but until 1943 in their main outlines they were the basis of the legal status of foreigners in China.

While at the time they seemed to solve a troublesome situation, they weakened Chinese sovereignty and threatened the existence of the state—partly by removing foreigners from Chinese jurisdiction, partly by their regulation of the tariff and partly by making Christian communities *imperia in imperio*.

The T'ai P'ing Rebellion and Other Revolts.—In addition to the problem of the occidentals, China was confronted by serious internal problems. By 1800 the population probably was three times as large as it had been at the beginning of the dynasty. Agriculture, industry and commerce had not been able to expand so rapidly. In some regions landlordism was widespread. Furthermore, the government had been growing corrupt; taxes grew heavier and the officials squeezed the people. After more than a century of internal peace rebellions began to break out. The great rebellion of the White Lotus society (1796–1803) in the western provinces was followed by many lesser uprisings which, though suppressed, were signs of serious socio-economic maladjustment. The dynasty was approaching a crisis.

In south China, particularly in Kwangtung, a number of additional factors stimulated disorder. The Hakka were an ethnic group which had migrated centuries before from north China and settled in Kwangtung and Kwangsi. They were in frequent conflict with the longer-established local population, and when economic troubles grew these conflicts increased. Secret societies with an anti-Manchu purpose were strong in south China. The illegal opium trade, carried on by smugglers, encouraged gangsterism and piracy, which became linked with the underground secret societies. After about 1820 opium was beginning to drain silver from China, which disturbed the economy, particularly that of Kwangtung. The first Anglo-Chinese war was a blow to the prestige of the Manchu dynasty. It also broke the government's naval power and weakened its ability to maintain order in Kwangtung against the league of pirates, gangsters and secret societies. During the 1840s in Kwangtung and Kwangsi the people suffered severe famines. Banditry increased; disorder was spreading. Conditions—both general and specific—made an uprising almost inevitable.

The T'ai P'ing rebellion, one of several that concurrently shook the imperial structure to its foundations, also had another ingredient—Christianity. The leaders of this rebellion were mostly Hakka. One of them, Hung Hsiu-ch'üan, an unsuccessful competitor in the civil service examinations, suffered a serious illness accompanied by bizarre visions. He later interpreted these in the light of some books prepared by Protestant missionaries which had been given to him years before in Canton. Believing he had been called by God to wean the Chinese from the worship of idols, he and his first convert, Fêng Yün-shan, began preaching their new religion in Kwangtung and Kwangsi. Their followers, mostly impoverished Hakka, were formed into religious communities that by 1848 were being welded into fighting units.

About this time Hung had an opportunity to study Christianity for about two months with a U.S. missionary in Canton. Conflicts between the Society of God Worshippers, mostly Hakka, and the non-Hakka authorities in Kwangsi burst into rebellion in 1850. By this time there were some secret society and pirate adherents in the movement.

Under skilful leadership and against very weak resistance from the government, the T'ai P'ing rebellion swept north from Kwangsi into Hunan and from there down the Yangtze, gathering thousands of supporters, until in 1853 the rebels took Nanking. Their serious expedition to the north failed, but at Nanking they ruled for more than a decade, a fanatical sect whose faith was an ill-assorted blend of misunderstood Christianity and native Chinese beliefs. They showed an utter lack of ability to organize their conquests and owed their temporary success more to the weakness of the imperial government than to their own prowess. They were eventually (1864) put down, chiefly by Tsêng Kuo-fan but with the aid of a picturesque foreign-officered force which was headed first by an American, Frederick Townsend Ward, and later by an English major, Charles George Gordon. The rebellion had cost millions of lives and had wasted some of China's fairest provinces.

During the T'ai P'ing rebellion the imperial government, in desperate straits for revenue, resorted to likin (internal transit taxes on commerce) and, the crisis once past, continued it. During the rebellion, too, as a convenience for the imperial authorities, the system began of collecting the maritime customs through the agency of foreigners. This expedient was first adopted in Shanghai but proved so acceptable to both Chinese and foreigners that it was extended to other ports. The imperial maritime customs service so developed was in 1863 placed under the direction of Robert Hart, and through his genius was officered by an able foreign staff and became not only a dependable source of revenue but an agency for the charting and lighting of the coasts and the inauguration of a postal system.

Other rebellions threatened the power of the Manchus, especially in Shensi, Kansu and Sinkiang, but these were all suppressed. The Manchu dynasty, indeed, for the moment took on a new lease of life. Able Chinese came to its support. The empress dowager, Tz'ŭ Hsi, who had had the good fortune to bear the heir of Hsien Fêng, ruled as coregent during the minority of her son, the emperor T'ung Chih, and then on his death (1875) obtained the succession for another minor—known by his reign name of Kuang Hsü—and was dominant not only during his boyhood but after her nominal retirement (1889). Unscrupulous but vigorous, she probably prolonged the life of the dynasty.

Increasing Foreign Pressure on China, 1860–94.—The years between 1860 and 1894 were marked by no major crises in China's foreign relations, and Chinese life and culture went on nearly unaltered by the presence of the westerner. Pressure was steadily accumulating, however, occasional minor clashes occurred, and the stage was being set for revolutionary changes.

From time to time new ports were opened, and through these and the ones previously available foreign commerce was growing. As before 1860, the British continued to lead. In the treaty ports foreign colonies arose, and in some of them special districts were set aside, usually either as "concessions" or "settlements" (some of them dated from before 1860), which, as a development of extraterritoriality, were under the administration of the foreigners, through the consuls, and some of them with a council elected by

the foreign taxpayers.

Christian missionaries, both Roman Catholic and Protestant, rapidly increased in number. The first Protestant missionary, Robert Morrison, of the London Missionary society, arrived in 1807, and under the impulse of the vigorous new life of Protestantism in Europe and the U.S. during the ensuing century representatives of many societies followed—British, American and European. Protestant missionaries emphasized the translation and distribution of the Scriptures and of religious and secular literature, preaching, schools, medical relief and the formation of churches. They were largely responsible for China's first contacts with western education and medical science.

Roman Catholics reinforced their missionary staffs, emphasizing the winning of converts and the care of children in orphanages. By 1890 Protestant Chinese numbered about 50,000 and Roman Catholic Chinese about 500,000.

The growing pressure of the west began slowly to take effect. Before 1895 no startling changes in the structure of Chinese life occurred, but here and there were indications that China would not remain as it had been. In the first place, it somewhat grudgingly began to enter into the diplomatic life of the world. In 1866 a Manchu was sent to Europe with Robert Hart to observe and report. In 1867 Anson Burlingame, who was retiring as United States minister in Peking, was asked to head a mission to present China's case to the governments of the west. Burlingame went first to the United States and there negotiated a treaty (1868) which among other things promised respect for the territorial integrity of China and freedom of immigration of Chinese labourers to the United States and reciprocal rights of residence and travel. From Great Britain and France the mission obtained assurances that pressure would not be applied inconsistent with the independence and safety of China. In 1870, after visiting several courts, and while in St. Petersburg, Burlingame died and his colleagues returned to China. The mission was much criticized, especially for Burlingame's optimistic speeches, but—with the exception of a much earlier one to Russia (1733)—it was China's first formal embassy to that west with which it must henceforth deal.

Before 1880 resident envoys had been appointed to most of the leading capitals of the world. In 1873 and again in the early 1890s the foreign envoys in Peking were given audience by the emperor, but always with a subtle suggestion that they were considered as coming from tributary states. Not until 1894 were they received on the basis of full equality.

In the 1870s, at the instance of Yung Wing, who had graduated from Yale university in 1854, the Chinese government sent several scores of youths to the United States to be educated, but in 1881 a conservative brought about their recall. Two government schools were founded to train men for diplomatic service. By 1894 telegraph lines and a few miles of railway were built, and some attempts were made to reorganize China's naval and military forces and to construct coast defenses according to western models.

The Chino-Japanese War and the Beginning of Rapid Changes.—China could not hope long to remain semi-isolated. The occident was continuing to expand, Japan, at China's very doors, was rapidly adopting and adapting western culture, and the Middle Kingdom must sooner or later adjust itself to the new world.

The beginning of rapid change was brought by war with Japan. Korea had long been in an ill-defined position of vassalage to China. Japanese, on the other hand, had invaded the peninsula at least twice, the latest occasion having been in the last decade of the 16th century. With its reorganization in the 1860s and 1870s, Japan again began to exert influence in Korea, and in doing so came into conflict with China, for the latter, under the advice of Li Hung-chang, was inclined—with some vacillation—to assert more actively than in the past its authority as suzerain. Japan refused to recognize China's suzerainty and the two nations came to blows over the dispatch of troops by both to put down an insurrection in Korea. War was declared Aug. 1, 1894, and China was quickly and overwhelmingly defeated. By March 1895 the Japanese had successfully invaded Shantung and Manchuria, had captured Wei-hai-wei and Port Arthur, fortified posts which commanded the sea approaches to Peking, and the Chinese sued for peace. By the resulting treaty (of Shimonoseki) China recognized the independence of Korea, ceded to Japan Formosa, the adjoining Pescadores Islands and the Liaotung peninsula (in Manchuria), agreed to pay an indemnity of 200,000,000 taels opened four more ports to trade and promised a satisfactory treaty of commerce. Russia was not disposed to see Japan make gains which would threaten Russian ambitions in the far east and, backed by its ally, France, and by Germany—which professed fear of the "yellow peril"—protested against the cession of the Liaotung territory. Japan had no other recourse but submission, and the retrocession to China was made in return for a face-saving increase in the indemnity. The war had demonstrated the utter failure of Chinese attempts at "self-strengthening" during the past three decades. Its "modern armies" had proved incapable of defending the country and its western-style navy had been destroyed.

The victory of Japan was the signal for a scramble among the powers for leases, concessions and special privileges. The weakness of the Middle Kingdom had been unmistakably disclosed and for a few years it looked as though the powers, driven by earth hunger and fear of one another, would partition it. Russian, French, British and German bankers angrily contested for shares in the loans through which China was to pay the Japanese indemnity. In 1895 Russia obtained permission to carry the Trans-Siberian railway directly across Manchuria instead of by the longer all-Russian route of the Amur and Ussuri. France secured a "rectification" of the frontier in the Mekong valley and railway and mining privileges in China. Great Britain, alarmed, demanded and received concessions on the Burmese frontier. Rumours were soon afloat (1896) of further grants to Russia in Manchuria and of a promise to that same power of a lease on Kiaochow bay in Shantung. Russia, too, extended its influence in Korea. In Nov. 1897 German forces seized Tsingtao, giving as an excuse the murder of German missionaries in Shantung, and the following March that port and land controlling Kiaochow bay were leased to Germany for 99 years, and railway and mining concessions in Shantung were assured. Russia made the German seizure of Tsingtao the signal for the occupation of Port Arthur and Talien (Dairen or Dalny), and in March 1898 a portion of the Liaotung peninsula which included these two ports was leased to Russia for 25 years. Within a few weeks France was given a 99-year lease to Kwangchowwan in Kwangtung, and Great Britain acquired Wei-hai-wei "for so long a period as Port Arthur shall remain in the occupation of Russia." Great Britain also acquired a 99-year lease on an additional portion of the Kowloon promontory, opposite Hong Kong.

Concurrently with the seizure of these leaseholds, the powers delimited "spheres of interest," by which they meant, by implication, prior rights to provide capital for the development of mines and railways, and the promise of nonalienation of territory to another power. In case China should be partitioned, spheres of interest might become formal annexations. In 1897 France secured from China a "declaration of nonalienation" of Hainan to any third power. In 1898 Great Britain obtained a similar declaration for the provinces adjoining the Yangtze, France for the provinces bordering on Tongking and Japan a promise that none of Fukien would be alienated to any power whatsoever. Germany claimed Shantung as its sphere and Russia the territory north of the Great Wall. In 1899 Russia and Great Britain agreed not to interfere in each other's preserves. Great Britain, too, exacted from China a promise that the inspector-general of the maritime customs should be of British nationality, at least so long as the trade of Great Britain exceeded that of any other country.

Still another form of the struggle for a slice of the Chinese melon was the competition for the privilege of providing capital for railways. The details of the story are extremely complicated, but in general the results were that Russia acquired a monopoly of railway building in Manchuria; Belgian financiers—behind whom France and Russia were suspected to stand—provided the money

for the road from Peking to Hankow; Germans furnished the capital for lines in Shantung and for the northern section of the road from Tientsin to Pukow (on the Yangtze, opposite Nanking), Britons for the southern half of the road and the line from Shanghai to Nanking, and France was granted concessions for railways in its sphere of interest—Kwangtung, Kwangsi and Yunnan. A U.S. syndicate was given the concession for a road from Hankow to Canton, but the Belgians later acquired a controlling interest in the company and the Chinese, irritated, bought back the grant. The French got from the Russo-Chinese bank the contract for a road connecting Tai-yüan with the Peking-Hankow line, and a Franco-Belgian syndicate the contract for a line from Kai-fêng to Loyang. Mining concessions, which need not be enumerated here, were also obtained by various foreign groups.

To prevent the threatened disruption of China three major and widely different efforts were made. One was by the United States. In the autumn of 1899, John Hay, the U.S. secretary of state, asked from England, France, Russia, Germany, Japan and Italy assurances that within their respective spheres of interest they would not interfere with any treaty port or vested interest, that no preferential harbour dues or railway charges would be given their subjects and that the Chinese government should collect the customs duties and only according to the Chinese tariffs. This "open-door policy" was not, strictly speaking, new, but was founded upon the most-favoured-nation clauses. Nor was it entirely disinterested. The United States held aloof, to be sure, from the scramble for leases and concessions, but this was partly because the U.S. was too engrossed in developing the virgin resources of its own land to engage in ventures abroad. Now, its acquisition of Hawaii and the Philippines, however, the United States had awakened to a livelier interest in the far east, and did not wish doors to be slammed in the faces of its merchants and bankers. All the powers assented to the U.S. note, although Russia did so with slight reservations.

The other major efforts to save China were by the Chinese themselves. After the war with Japan clubs sprang up advocating "reform"—organization on the occidental pattern. That, so the members urged, had been the secret of Japan's victory. The great viceroy Chang Chih-tung came out with a widely read pamphlet *Learn*, urging reform, although without the abandonment of the best of China's heritage. Some of the extremists, notably the brilliant but erratic K'ang Yu-wei and his disciple Liang Ch'i-ch'ao, a master of Chinese style, obtained the ear of the emperor, and for a little more than three months in the summer of 1898 edict after edict poured forth from Peking ordering some of the changes which the radicals desired. Compared with what was to happen in the next 25 years, these were moderate enough, but at the time they seemed revolutionary.

The civil service examinations were to be reformed, new schools with western as well as Chinese subjects were to be founded, western military methods and equipment were to be introduced and steps taken looking toward a national army based on conscription, reforms in the courts of law were projected, a government bureau to translate foreign works and a ministry of arts, commerce and agriculture were to be established, patent and copyright laws were to be introduced and rewards offered to authors and inventors, annual budgets of receipts and expenditure were sanctioned and many sinecure offices were abolished.

Skilled statesmen might have succeeded in carrying through these reforms without provoking a major crisis, but the young emperor knew little of the world of men outside his palace walls, and his radical advisers had little or no experience in government. The inevitable storm, therefore, was intensified, and in Sept. 1898 the empress dowager suddenly intervened and inaugurated a third effort to save China—by a return to the conservative *status quo*. The coup d'état was precipitated by the emperor's plan to thwart the reactionaries by placing restrictions on the empress dowager and executing her most loyal henchman, Jung Lu. Information seems to have come to Jung Lu through Yuan Shih-k'ai, and Tz'ŭ Hsi acted promptly. On Sept. 22, 1898, she reassumed the reins of government. She kept the emperor a virtual prisoner and but for the powers might have had him assassinated. As many reformers as could be apprehended were executed, and most of the reform decrees were annulled. Tz'ŭ Hsi attempted to restore the government as it had been and to strengthen it to resist foreign encroachments.

The Boxer Uprising, 1900.—On the heels of the conservative reaction, and in part as a consequence of it, came a blind attempt, largely popular but sanctioned by the extremists, to oust the foreigner once and for all. In 1898 and 1899 unrest was widespread, induced partly by the talk of reform, partly by the aggressions of the powers and partly by the vigorous reaction led by the empress dowager. The government, in an attempt to provide for the national defense against foreign aggression, ordered the revival of the village trainbands or militia and put the plan into effect first in the northeastern provinces. Into these trainbands came many of the local rowdies, and here and there disorderly secret societies affiliated with them. The members practised rites which they believed would make them invulnerable to bullets and came to be known to foreigners as "Boxers"—a loose translation of the Chinese name for the bands, I Ho T'uan or I Ho Ch'üan, "Righteous Harmony Bands" or "Righteous Harmony Fists."

One of the favourite mottoes of the Boxers was "Protect the country, destroy the foreigner." By the autumn of 1899 the Boxers were beginning to persecute Christians—as "secondary foreign devils"—especially in Shantung, where the antiforeign Yü Hsien was governor. The powers, alarmed, brought pressure, and, while they obtained the recall of Yü Hsien, he was soon appointed to the governorship of Shansi and unrest increased. An English missionary was murdered the last day of 1899, and by the following June the attacks on Chinese Christians became more frequent and foreigners were in grave danger.

In early June 1900 an unsuccessful attempt of the powers to throw additional troops into Peking aggravated the situation, and when, on June 17, foreigners seized the Taku forts to open the way to Tientsin and Peking, the storm broke. Against the counsel of saner heads, the empress dowager ordered all foreigners to be killed. The German minister was murdered, and the other foreign ministers and their staffs, missionaries and hundreds of Chinese Christians were besieged in the legation quarter and in the Catholic cathedral in Peking. Scores of Roman Catholic and Protestant missionaries and thousands of Chinese Christians were done to death, principally in Hopei, Shansi and Manchuria. The powers declared that they were not waging war on China but were simply seeking to rescue their nationals and to suppress the Boxers. The viceroys in the Yangtze valley and the south opposed Boxerism and accordingly remained neutral and endeavoured to repress antiforeign outbreaks within their jurisdiction. That attitude was also taken by high officials in most of the west and north. The disorders, therefore, were chiefly confined to the northeast. An international force captured Peking on Aug. 14, 1900, the court fled to Sian, and the foreign troops proceeded to loot the capital and then to relieve scattered groups of missionaries and Christians who had been standing siege and to disperse the Boxer remnants.

Although the powers had not declared war on China, they deemed a formal settlement necessary to exact reparation and to guard against a recurrence of the outbreak. After negotiations, which were prolonged by disagreements among the victors, in Sept. 1901 a protocol was finally signed.

This document provided for the punishment, by China, of some of the officials held chiefly responsible; for memorial monuments for some of the murdered foreigners; for formal missions of apology to Berlin for the death of the German minister; for the suspension for five years of civil service examinations in towns where foreigners had been killed or mishandled; for the prohibition for at least two years of the importation of arms and ammunition; for an indemnity of 450,000,000 taels, to be paid in 39 years and to be secured by the revenues of the imperial maritime customs; for the fortification and policing by foreigners of the legation quarter, the razing of the Taku forts and the maintenance by foreign troops of communication between Peking and the sea; for edicts against antiforeign agitation; for

the amendment of the existing commercial treaties; and for transforming the foreign office (Tsungli Yamen) into the chief of the ministries of state, under the name of the Wai Wu Pu.

The Era of Change to the Overthrow of the Manchus, 1900–11.—The Boxer year inaugurated momentous changes. The empire was clearly at the mercy of the powers, and foreigners acted as though they were living in a conquered country. With the exception of Manchuria, encroachments on Chinese sovereignty were less marked than in 1898 and 1899. The Russians continued their aggressions. The disorders of 1900 had spread to Manchuria, and thither Russia quickly dispatched large bodies of troops, ostensibly to protect its subjects and investments. The Russian forces ruthlessly suppressed all opposition and occupied much of the three provinces. Late in 1900 an agreement between China and Russia promised the latter extensive control in southern Manchuria and was modified only on protest from the other powers. Both Great Britain and Japan were alarmed, the former because of its general fear of Russia in the east and the latter because of the threat to Korea, where Russian machinations were increasing. In defense against the common foe, the Anglo-Japanese alliance was formed (Jan. 30, 1902). Russia, subjected to pressure from these two powers and the United States, promised to respect the commercial rights of all nations, and agreed with China (1902) gradually to withdraw Russian troops from Manchuria. However, Russia found pretexts for delays and sought from China, in return for evacuation, compensations which would have strengthened its hold on the debated territory.

Great Britain, the United States and Japan sought to check Russia. Japan was especially concerned and strove by direct negotiations with St. Petersburg to obtain recognition of its interests in Korea and the promised evacuation of Russian troops from Manchuria. Russia was obdurate and Japan had recourse to arms (Feb. 1904). In the ensuing months the Japanese captured Port Arthur, drove the Russians out of southern Manchuria and destroyed the Russian fleets. In 1905 Pres. Theodore Roosevelt proffered his good offices, hostilities were suspended, and by the resulting treaty of Portsmouth (Sept. 5, 1905) Russia recognized Japan's interest in Korea, transferred to Japan Russian rights in the Liaotung peninsula, ceded to Japan the southern section of the Manchurian railway and the southern half of Sakhalin, and both powers agreed to withdraw their troops from Manchuria, to use the railways in Manchuria, except those in the Liaotung peninsula, only for economic and industrial and not for strategic purposes, and not to obstruct "measures common to all countries which China may take for the development of the commerce and industry of Manchuria."

The war merely substituted Japan for Russia in southern Manchuria, and the former was no more scrupulous in respecting China's rights than was the latter. Many Japanese contended, indeed, that having spent blood and treasure for Manchuria they had better rights there than the Chinese. By the annexation of Korea (1910) Japan moved its boundary to the southeastern edge of Manchuria and strengthened its interests in Kirin and Liaoning, the southern two of the three provinces.

The suppression of the Boxer outbreak by the powers and the subsequent war between Japan and Russia seriously weakened China. The governmental machinery, which had worked fairly well as long as China had not been in intimate touch with nations as powerful as itself, proved inadequate to meet the strain imposed by the coming of the occident. The Manchus would have to show unusual ability if they were to save their throne, and the Chinese if they were to avoid anarchy.

After 1900 and especially after 1905 both Chinese and Manchus set about the reorganization of the country. Even the most conservative could not fail to read the signs of the times, and the empress dowager, doubtless reluctantly and with many misgivings, attempted to direct the reform which she could no longer avert. In 1902 the court returned to Peking and the empress dowager set herself to win the friendship of the foreigners, addressing herself especially to the ladies of the legations.

Much more important was the sanction which she gave to decrees which sought to aid and to regulate the introduction of western civilization.

In 1902 orders were issued to remodel public instruction by the creation of new schools and by the introduction of western subjects in the curriculum. In Sept. 1905 a decree was promulgated abolishing that most characteristic feature of the old educational system, the civil service examination. Partly as a result of these orders and partly in consequence of the general movement for reform, schools teaching Chinese and western subjects sprang up by the thousand. The old examination stalls were razed and on some of the sites rose buildings dedicated to the new learning. Many temples were converted for educational purposes. By the end of 1910 there were 35,198 government schools with 875,760 pupils. Protestant mission institutions, once the unpopular representatives of a new learning, were now thronged and new ones were opened. Students by the thousand flocked to Japan, there to study in modern schools, and hundreds went to Europe and the U.S. When in 1908 the United States announced its purpose to return a portion of its share of the Boxer indemnity, the sums remitted were set aside for scholarships to enable Chinese to study in the U.S. With the new schools came a flood of literature treating of western ideas, and publishing houses, notably the Commercial Press, arose to give it circulation.

With educational reform went efforts to put the country in a better state of defense. The foreign drilling of the northern army continued; throughout the country troops were trained in the new ways, greater honours were paid to military officers, and in 1906 steps were taken toward the creation of a national force as contrasted with the older provincial forces.

In 1910 slavery was abolished, but since that institution was never so prominent in China as in parts of the occident the step did not entail marked revolution. Vigorous efforts were made to stamp out the opium trade, an imperial edict of Sept. 1906 inaugurating the campaign. The British government, under whose protection much of the foreign trade in the drug was carried on, in 1907 agreed to reduce the importation concurrently with the progressive abolishment of the domestic growth of the poppy, at a rate which would extinguish the trade in ten years. The restriction on poppy growing proved so much more rapid than was anticipated that in 1911 Great Britain agreed to the complete exclusion of the foreign drug from the provinces where the culture had ceased.

Governmental reorganization also was undertaken. In 1902 a commission on juridical reform was established and in 1905 reported, recommending the modification of the laws. As a beginning, torture, except in criminal cases, and certain cruel forms of punishment were ordered to be abolished. The reorganization of laws and judiciary was not sufficiently thoroughgoing, however, to cause the powers to dispense with extraterritoriality. The reform of the currency was discussed, but nothing effective was accomplished, and with the appearance of new coins the previous confusion became worse confounded.

Most important of all the governmental reforms was the attempt to introduce a constitution with representative assemblies. In 1905 a commission was sent abroad to study constitutional methods, and on its return in 1906 a promise was made to introduce a parliamentary form of government. That same year, as a preliminary, changes were made in the organization of the central administrative boards in Peking.

In Aug. 1908 an edict promised the convocation of parliament in nine years, but the death of the emperor and of the empress dowager in November of that year brought postponement. The new emperor, a nephew of the childless Kuang Hsü, was an infant of 2½ years, and his father, Prince Ch'un, was appointed regent. The new reign was given the title of Hsüan T'ung. Shortly after its beginning the regency was deprived of the support of one of the strongest Chinese by the forcible retirement of Yuan Shih-k'ai, as a punishment, so rumour had it, for his alleged betrayal of the regent's brother, the late emperor, in 1898.

Constitutional reform was only delayed by the change in rulers, and that briefly. In 1909 provincial assemblies met, chosen by a limited electorate, and in Oct. 1910 the national assembly convened, half of it elected and half appointed by the throne. The

national assembly demanded the right to legislate, but for the time could gain merely the promise of the convocation of a parliament with legislative powers in 1913 rather than in 1917.

Along with changes in education and government went other sweeping alterations in the nation's life. Several of the railways authorized before 1900 were constructed, bringing great modifications in transportation. Foreign shipping increased on the coastal waters and the Yangtze, telegraph lines were extended, and the business of the post office multiplied. Foreign commerce more than doubled in the decade after 1901, and foreign merchandise penetrated to the remotest hamlets. The numbers of missionaries rapidly increased, and both the Catholic and Protestant communities showed a phenomenal growth.

After 1900 a more radical movement looking toward overthrow of the Manchu dynasty began to gain strength among Chinese abroad and to penetrate secretly into the empire. Revolutionary leaders found recruits among the thousands of Chinese students studying in Japan. On their return to China many of these students secured positions of influence in education, journalism and the army. Magazines preaching revolution as well as those urging reform were printed in Japan and smuggled into China.

Merchants overseas contributed funds. Anti-Manchu secret societies in south and west China were rejuvenated. Several short-lived uprisings occurred. Sun Yat-sen and Huang Hsing were but two of many revolutionary leaders.

The Passing of the Manchus.—In 1912 the rising tide of change swept aside the Manchus. Ever since the conquest in the 17th century most of the Manchus had lived in comparative idleness, supposedly a standing army of occupation, but in reality inefficient pensionaries. All through the 19th century the dynasty had been declining, and in the death of the empress dowager it lost its last able leader. In 1911 the emperor was an infant and the regency utterly incompetent to guide the nation through the stormy waters ahead. The unsuccessful contests with foreign powers had shaken not only the dynasty but the entire machinery of government. The ferment of new ideas was already weakening the ancient wineskins, and only strong and wise leadership could prevent loss to both. Under the circumstances almost any incident might have toppled the Manchus off the throne.

The chain of events immediately leading to the revolution began with the signing (April 5, 1911), with a four-power group of foreign bankers, of the Hukwang railway loan agreement for the construction of roads in central China. The Peking government decided to take over from a local company a line in Szechwan, on which construction had been barely begun, and to apply part of the loan to its completion. The sum offered did not meet the demands of the stockholders, and in Sept. 1911 the dissatisfaction boiled over into open revolt. On Oct. 10, in consequence of the uncovering of a plot in Hankow which had little or no connection with the Szechwan episode, a mutiny broke out among the troops in Wuchang, and this is regarded as the formal beginning of the revolution. The mutineers soon captured the Wuchang mint and the arsenal at Wuchang, and city after city declared against the Manchus. The regent, panic-stricken, granted the assembly's demand for the immediate adoption of a constitution, and urged Yuan Shih-k'ai to come out of retirement and save the dynasty. Yuan, after much hestitation, accepted on his own terms, and at the end of October took the field at the head of the northern armies. In November he was made premier.

Had Yuan acted vigorously he might have suppressed the uprising and so have delayed the inevitable. He dallied, however, and by the end of the year 14 provinces had declared against the Manchus, in several cities Manchu garrisons had been massacred, the regent had been forced out of office, a provisional republican government had been set up at Nanking, and the archrevolutionist Sun Yat-sen had returned from abroad and had been elected president.

In December Yuan agreed to an armistice and entered upon negotiations with the republicans. On Feb. 12, 1912, the boy emperor was made to abdicate the throne in a proclamation which transferred the government to the people's representatives, declared that the constitution should thenceforth be republican and gave Yuan Shih-k'ai full powers to organize a provisional government. The Nanking authorities agreed that the emperor was to retain his title for life and to receive a large pension. To unify the country, Sun Yat-sen resigned the presidency and Yuan was chosen in his place. Li Yuan-hung, who had come into prominence in Wuchang in the initial stages of the rebellion, was elected vice-president. A provisional constitution was promulgated in March 1912 by the Nanking parliament, and in April the government was transferred to Peking.

The republic, established with such startling rapidity and comparative ease, was destined to witness the progressive collapse of national unity and orderly government. The causes for this chaos were, in the main, three. In the first place, traditional processes were being repeated. The demise of every dynasty had been followed by civil strife, in which rival military chieftains struggled for the throne. The disorder usually lasted for decades, and once, after the downfall of the Han dynasty, was prolonged for nearly four centuries.

The peaceful transfer of power to Yuan Shih-k'ai under the guise of a republic for a time mitigated the struggle and even seemed to have averted it. Yuan, however, did not prove strong enough to hold the country together. Until after 1928 no one else came as near to success as did he, and the country was broken up into ever-smaller fragments, most of them ruled by military chieftains. Figures came and went from the political stage with bewildering rapidity, and after Yuan's death (1916) the political map was seldom the same two years in succession.

In the second place, the chaos was accentuated by new ideas from the west. The governmental machinery which on the whole had worked better over a longer period than any other ever devised for so numerous a people was being abandoned. It was ill adapted to the new conditions, and theoretical radicals, imbued with occidental ideas, and militarists tended to ignore it or to modify it more greatly than at any time since the Han. Such thoroughgoing political experimentation meant chaos, and new institutions were not quickly evolved for so enormous a section of mankind.

In the third place, the disorder was increased by the interference of foreigners. Japan was vitally concerned in the fate of its huge neighbour. Its population was steadily increasing, no adequate relief could be had through emigration, and its only recourse was to add to its income by engaging in industry and commerce. If it were to do this, it must have access to raw materials, including coal and iron, and to markets. For these it most naturally looked to the adjoining continent and especially to China. Japan's life depended, therefore, upon keeping open the door into China, and it is not surprising that it sought to control portions of the republic and at times meddled in Chinese politics. To Japan were added the western powers, especially Russia. Beginning about 1922, but especially after 1925, Russian Communists sought to extend their influence into China and to foment the kind of revolution which they had achieved at home.

It must be noted, however, that foreign activities helped to bring union as well as disunion. Resentment against the foreigner was the one issue on which the vocal elements of the nation could unite; railways and telegraph lines—both of foreign origin—helped to bind the country together, and the foreign-controlled customs service and the foreign-organized postal system were the only governmental agencies which continued to function over all the country.

The Republic Under Yuan Shih-k'ai.—For four years Yuan Shih-k'ai was able to delay the further disintegration of China. He faced no easy task. The radicals, who in Aug. 1912 took the party name of Kuomintang, regarded him with suspicion, and, obtaining a majority in the parliament which assembled in 1913 under the provisional constitution of 1912, demanded a type of government in which the legislature should be supreme and the president a figurehead. Rival military leaders were beginning to appear, and grave financial difficulties faced a government whose fiscal machinery, already decrepit, had been disturbed by the revolution. The confidence of the powers, moreover, was not yet given the new regime.

In the face of all these difficulties Yuan for a time achieved marked success and gradually restored in the provinces the authority of the central government. In April 1913, after prolonged negotiations, he concluded a "reorganization" loan with a financial group representing Great Britain, France, Russia, Germany and Japan. The loan, a large one, was secured by a lien on Chinese revenues, chiefly on the income from the salt monopoly —now put under foreign supervision. His financial position and the moral support of the powers thus assured, Yuan proceeded to defy the members of the Kuomintang. The latter had sought to block the loan and saw in its conclusion grave danger to themselves. They continued obstructionist policies, and, as Yuan still prevailed, in the summer of 1913 some of them, including Sun Yat-sen and Huang Hsing, declared a "punitive" expedition against him and for a while held Nanking. Yuan promptly put down the rebellion, and, after obtaining the ratification of the articles of the "permanent" constitution which had to do with choosing the president, and being elected under them (Oct. 1913), he outlawed the Kuomintang (Nov. 1913) and unseated its members of parliament. A few weeks later he disbanded what remained of parliament, replacing it with an administrative council selected by himself. In March 1914 the provincial assemblies were dissolved. A new constitution, framed by a body controlled by Yuan, was promulgated in May 1914. The president's power was greatly strengthened, his term was lengthened to ten years, and he might be rechosen by the council of state or control the election of his successor. In 1914 Yuan performed the imperial ceremonies in the Temple of Heaven at the winter solstice. He seemed to be winning against the opposition and in 1915 prepared to take the further step of having himself formally chosen and proclaimed emperor.

However, opposition developed both within China and among various foreign powers, particularly Japan, which was supported by its wartime allies Great Britain, France and Russia. A rebellion broke out in Yünnan and spread to other provinces of the south. The Kuomintang established a rival government at Canton. Opposition was so formidable that Yuan rescinded the monarchy in March 1916; on June 6 he died.

With Yuan removed, the country appeared quickly to unite. Li Yuan-hung, unopposed, succeeded to the presidency; Tuan Ch'i-jui, appointed by Yuan in the last few weeks of his life, continued as premier and brought to the support of the new government some of the northern military chiefs. The parliament of 1913, reassembling, brought back to Peking many of the Kuomintang. The government seemed to be further strengthened by the election to the vice-presidency of Fêng Kuo-chang, dominant in the lower part of the Yangtze valley.

The very strength of the new government was, however, its weakness, for it was made up of elements which were fundamentally discordant and which any crisis might set at loggerheads. This crisis was to grow out of international reactions in which China was inextricably involved.

Foreign Relations, 1911–17.—The revolution did not immediately bring marked change in China's foreign relations. Tibet and Outer Mongolia, at best never very firmly attached to the empire, took the opportunity afforded by the shift in governments to effect their virtual independence, and Great Britain in the former case and Russia in the latter were not slow to attempt to extend their influence over territories which abutted so directly upon their own. China recognized the autonomy of Outer Mongolia in return for the acknowledgment of Chinese suzerainty, but it was less pliant in yielding to British ambitions in Tibet. On the whole, the powers made little objection to the establishment of the republic.

The outbreak of World War I, however, brought serious difficulties. With Europe absorbed in internecine strife, Japan saw a golden opportunity to extend its power in China. The Anglo-Japanese alliance afforded it a welcome excuse for seeking to eliminate Germany from the far east. Accordingly, in Aug. 1914 Japan dispatched an expedition to Shantung and, with the cooperation of a small British force, captured Tsingtao and the other German possessions in the province.

The occupation of the German properties in Shantung was only a beginning. In Jan. 1915 Japan presented to Peking a formidable array of 21 demands in five groups.

1. In Shantung, China was to agree to any transfer of German possessions to Japan that the latter might obtain. China was not to alienate to a third power any territory in the province; it was to declare additional cities to be open ports and was to grant certain railway privileges.

2. In south Manchuria and eastern Inner Mongolia, the leases of Port Arthur, Dairen (Dalny) and the railways were to be extended to 99 years. Anywhere in these regions, Japanese might lease land and travel or reside. There were also demands for mining and railway privileges and for Japanese control of loans and the employment of Japanese official advisers.

3. The Han-yeh-p'ing company, the largest Chinese iron-mining and smelting concern, was to be made a Chino-Japanese enterprise, and China was not to sell its interest in it without Japan's consent.

4. China was to promise not to cede or lease to any third power any harbour, bay or island along its coast.

5. China was to employ Japanese as advisers to the central government; the police departments in certain districts were to be jointly administered by Japanese and Chinese; China was either to buy 50% or more of its munitions from Japan or to establish a Chino-Japanese arsenal which was to use Japanese materials under the direction of Japanese; Japanese were to be granted the privilege of buying land in the interior for schools, hospitals and churches; certain railway concessions in the Yangtze valley were to be promised; and Japan was to be allowed to scrutinize all proposed loans of foreign capital for mines and works in Fukien.

Japan attempted to keep the demands secret, but they became known and a wave of indignation swept over China; criticism also was expressed publicly and vigorously in Great Britain and the United States. The Japanese were constrained to make important concessions, but they had the upper hand and knew it; they presented an ultimatum to which China, helpless, had no recourse but submission. By a series of treaties and exchange of notes China agreed to the first three groups, with important modifications in its favour; group 4 was met by a presidential mandate which directed that no part of China's coast should be ceded to any power; and group 5 was reserved for further negotiations except for a promise from China that no nation should be permitted to construct a dockyard, a coaling station or a naval base on the coast of Fukien.

In February and March 1917 Japan made secret arrangements with Great Britain, France and Italy whereby those powers assured their support to Japanese demands at the peace conference for the former German holdings in Shantung.

China's Entrance Into World War I and Further Internal Difficulties.—As World War I progressed, pressure was brought upon China to enter the struggle on the side of the Allies. In Feb. 1917 the United States invited the Chinese government to follow its example in protesting against Germany's submarine campaign and severing diplomatic relations, and the Franco-Japanese secret notes of March 1, 1917, promised Tokyo's support to the effort to induce Peking to take the step. On Feb. 9 the Chinese foreign office sent warning to Germany and on March 14 broke off diplomatic intercourse.

The question whether China should actually declare war became an issue which precipitated a contest among the principal military successors of Yuan Shih-k'ai for control of the government. The step was taken on Aug. 14, 1917, when China formally declared war on Germany. The country had already begun, however, to disintegrate politically.

The Kuomintang members of the dismissed parliament denounced the Peking government as illegal, and, under the leadership of Sun Yat-sen, in Sept. 1917 organized a provisional government which they declared to be the only constitutional one in China. The powers did not grant it recognition, however, and it maintained a precarious and chequered existence, usually with headquarters at Canton. In the north Tuan Ch'i-jui and his sup-

porters, the so-called Anfu group, were for several years in the ascendant.

China's Part in World War I.—In the meantime World War I was drawing to a close. China's internal discord and financial straits were such that it could take no active part in the struggle, although it permitted the recruiting of about 175,000 of its citizens for labour battalions for service behind the lines in France, Mesopotamia and Africa.

China gained slightly by its entry into the war. It took over the German and Austrian concessions in the ports, cancelled the unpaid portions of the Boxer indemnities due its enemies and was permitted to suspend for the time payments on the sums due to the Allies. China was assured a seat at the peace conference.

In contrast with these gains, however, was an increased control by Japan. In Nov. 1917 the United States, in an effort to adjust its difficulties with Japan, entered upon the Lansing-Ishii agreement (terminated March 30, 1923), by which it recognized that because of "territorial propinquity . . . Japan had special interests in China," and so seemed to have delivered the latter over to the island empire. The Anfu clique around Tuan Ch'i-jui concluded agreements with Japan for the construction of railways in Shantung, Manchuria and Mongolia (Sept. 1918) and borrowed extensively from the Japanese on the security—some of it extremely dubious—of railways, mines, forests, telegraphs, taxes and bonds.

The Peace Conference.—To the peace conference which terminated the war the Chinese sent an able delegation representing, by a strange but characteristic anomaly, both the Peking and the Canton governments. The delegation asked not only for the restoration to China of the former German properties in Shantung, but for the cancellation of spheres of influence, the withdrawal of foreign troops, post offices and wireless and telegraphic communications, the abolition of consular jurisdiction, tariff autonomy, the relinquishment of leased territories and the restoration of foreign concessions and settlements. China was, however, doomed to disappointment. The U.S. delegation favoured the restoration of the Shantung properties, but against it were the agreements of 1917 between Japan and the European Allies. By the treaty of Versailles, therefore, Japan was confirmed in the possession of its holdings in Shantung. The remaining questions were held not to come within the purview of the conference.

When news of the Versailles settlement reached China there was immediate widespread protest. Students in Peking began a demonstration on May 4, 1919, against the pro-Japanese government. This patriotic movement spread rapidly to other cities and won the support of other groups in the population. The Peking government had to instruct the Paris delegation to refuse to sign the treaty with Germany. A very effective nation-wide boycott against Japanese goods was also instituted by patriotic groups. This patriotic outburst, known as the May 4 movement, had wide ramifications. It developed under the leadership of western-trained professors and their university students into a broad movement for reform and rejuvenation of Chinese life in all aspects.

China was not, however, to emerge from the war without some gains. It obtained membership in the League of Nations by signing the treaty with Austria, for that document did not contain the objectionable Shantung clauses, and in its separate treaty with Berlin the German share of the Boxer indemnity and German extraterritorial privileges were cancelled. A significant breach had been made in the wall of foreign "rights" in China.

The Washington Conference.—After the war the U.S. continued its active participation in Chinese affairs by bringing about (1920) a financial consortium whose purpose it was to assume international control of all further foreign loans to China and so to prevent the granting of special privileges to individual nations.

In 1921 and 1922, moreover, the United States called the Washington conference (*q.v.*), and China again had the opportunity to lay its case before the world and to ask for the elimination of the special privileges that foreigners enjoyed within its borders. Not all the agreements and treaties which arose out of the conference affected China, but the Chinese question loomed larger than any other except possibly that of disarmament. The most important actions, in so far as they concerned China, were as follows:

1. The treaty limiting naval armaments and fortifications had the effect of confirming Japan in the domination of the northeastern coast of Asia. No sea power could now hope easily to penetrate by force through its curtain of islands to the coast of China, as the United States and Great Britain found to their sorrow after 1941.

2. Nine powers agreed by treaty to respect the sovereignty, independence and territorial and administrative integrity of China, to give China opportunity to develop a stable government, to maintain the principle of equal opportunity in China for the commerce and industry of all nations and to refrain from taking advantage of conditions in China to seek special privileges that would abridge the rights of subjects or citizens of friendly states.

3. The customs schedule of duties was within four months to be raised to an effective 5%, and provision was made for the convening of a special tariff conference and for the periodical readjustment of the customs tariff.

4. A board of reference was to be established in China to which questions connected with the enforcement of the "open door" and equal railway rates could be referred.

5. A resolution expressed the sympathy of the powers with China's desire to see removed "immediately or as soon as circumstances will permit existing limitations upon China's political, jurisdictional and administrative freedom," and provided for the early establishment of a commission to inquire into the practice of extraterritoriality in China and the progress in judicial reforms.

6. On Jan. 1, 1923, foreign postal agencies in China were to be abolished.

Several other resolutions expressed the good intentions of the powers toward China.

The Washington conference also afforded Japan and China an opportunity to come to an understanding over the thorny Shantung question. Following the signing of the treaty of Versailles, Japan had made attempts to adjust the dispute, but always on conditions which had been repulsed by the Chinese. Now, however, Japan adopted a much more conciliatory attitude, and an agreement was reached whereby the former German holdings in Shantung were to be returned to China. However, the Japanese retained a share in some mines in the province and large commercial interests and landholdings in Tsingtao.

Several of the promises made to China at Washington were carried out. The foreign post offices were discontinued at the designated time. A special conference on the tariff convened in Peking in Oct. 1925 and, going beyond the assurances previously given, permitted the consideration of the entire question of tariff autonomy. Because of the disintegration of the Chinese government, the gathering broke up before a treaty was framed, but the foreign delegates agreed to the removal of tariff restrictions and consented to the putting into effect of the Chinese national tariff law on Jan. 1, 1929. The Chinese for their part promised to enforce the national tariff law and to abolish likin, long obnoxious to foreigners, on the same date.

Japan, moreover, continued conciliatory. While it declined to accede to the Chinese demand, made in 1923, for the abrogation of the agreements of 1915, until 1931 it entered upon no new marked aggression.

The powers also seemed about to remit the unpaid portions of the Boxer indemnity. The United States acted finally in May 1924, and Great Britain, France, Japan and Russia took preliminary steps looking toward the same end. All plans for remission, however, called for the allocation of the funds to educational or other cultural projects.

Domestic Politics After World War I.—While China was making progress toward regaining the special privileges which had been wrested from it by the powers, internally its government was rapidly disintegrating.

At the close of World War I, it will be recalled, Hsü Shih-ch'ang was in the presidential chair and Tuan Ch'i-jui was in control. A separate government was maintained at Canton, largely by members of the Kuomintang, under the leadership of Sun Yat-sen. For a time Sun was ousted from Canton by a Kwangsi faction, but he was restored by Ch'en Ch'iung-ming, and in April 1921 he was elected "president of the Chinese republic" by such members of the parliament of 1913 as could be got together. However, he secured only a precarious foothold in Canton and a part of Kwangtung. Most of southern China was a medley of petty factions and quarrelling war lords.

Conditions were little better in the north. In 1920 the outstanding leaders were Wu P'ei-fu, his titular superior, Ts'ao Kun, and Chang Tso-lin, the master of wealthy Manchuria. In the summer of 1920 these three united to drive Tuan and the Anfu leaders out of power. Wu P'ei-fu and Chang Tso-lin could not long co-operate, and in 1922 Wu defeated the latter and drove him back into Manchuria.

Wu now took steps which he hoped would unify the country. Hsü Shih-ch'ang resigned the presidency, Li Yuan-hung was reinstated in that office, and the parliament of 1913 was recalled to Peking. Thus the last officers around whom the entire country had seemed to unite were put back into power.

Hopes for a unified China, however, proved illusory. Funds were insufficient, cabinets unstable, parliament venal and militarists intransigent. The disintegration that set in after the death of Yuan Shih-k'ai became complete. China was torn by rival military factions which year after year launched campaigns against each other, conscripted troops, levied burdensome taxes and disrupted the economy.

Nationalism and Communism.—During the early years after World War I two interrelated developments of great significance occurred: the rise of nationalism and the emergence of the Chinese Communist movement. The Communist party was founded by a group of intellectuals, some of them leaders in the May 4 movement, who had turned to Marxism for a possible solution to China's weakness and political instability. With the help of an adviser from the Comintern, the party was organized in July 1921, though there were then only a few score members. The party devoted itself at first to organizing labourers and publishing propaganda journals. In Moscow the Communist international at its second congress in July-August 1920 had adopted a strategy with respect to colonial peoples that called in the first place for co-operation between Communists and other parties in movements for national liberation. Applied to China, this strategy was interpreted to require an entente between the Communist party and the Kuomintang. It took several years for Comintern agents to convince both parties of the desirability of this program. By the summer of 1923, however, the details had been worked out and the U.S.S.R. had promised help to Sun Yat-sen, who was attempting to establish a government in Canton.

In Sept. 1923 Mikhail M. Grusenberg, better known as Michael Borodin, arrived in Canton and soon became Sun Yat-sen's adviser in a program of reorganizing the Kuomintang into a strong, disciplined and centralized party. Communists were to be admitted to the Kuomintang as individuals and to assist in an attempt to reunite the country and free it of foreign encroachments. Russian advisers, money and arms flowed into Canton to aid in the creation of a Nationalist army. After Sun's death on March 12, 1925, his party glorified him as a national hero and elevated his Three Principles of the People—nationalism, democracy and livelihood—into a bible.

In the latter part of 1925 the Nationalist movement was directed sharply against Great Britain, the occasion being a sequence of clashes between British authorities and Chinese in Shanghai and Canton during which many Chinese were killed. Hong Kong was tied up for months by boycott and widespread strikes. Patriotic students flocked to the Kuomintang and many into the Communist party as well. Communist members of the Kuomintang were particularly active in the anti-imperialist movement and in organizing labourers and poor peasants to demand better economic conditions. The movement at Canton under the leadership of Borodin and some of Sun's more radical lieutenants veered increasingly to the left. In the meantime the new Nationalist army was consolidating the power of the Kuomintang in Kwangtung.

Not all leaders of the Nationalist party approved of the Communists, but some hoped to use them to achieve Nationalist aims. The Communists likewise hoped to use the Kuomintang. Great tension existed within the coalition.

In the summer of 1926 the Nationalist armies, led by Chiang Kai-shek, began a triumphant march northward, and by winter they had driven Wu P'ei-fu into Honan and practically eliminated him, were in possession of the Wuhan cities—Hankow, Wuchang and Hanyang—and the Kuomintang had moved its capital to Hankow.

The victories had been achieved as much by skilful propaganda as by force of arms. Wherever the Nationalist forces came, trained agitators directed popular sentiment against the treaties and foreign merchants and against Christian schools, churches and hospitals as imperialistic.

Kuomintang agitators also organized labourers and peasants to make exorbitant demands of employers and landlords, and in some places, notably Hunan and Hupeh, a reign of terror followed in which many of the propertied class were dispossessed and even executed.

Educated Chinese, weary of the long civil strife and smarting over China's feeble position among the nations, hailed the advance of the Kuomintang as the harbinger of better days. That advance continued with amazing rapidity, and by March 1927 the Chinese had taken over the British concessions in Hankow and Kiukiang; British and U.S. merchants and missionaries were being evacuated from much of the Nationalist territory; Sun Chuang-fang, recently strongly entrenched in Chekiang and Kiangsu, was in full flight, his armies a disorganized rabble; and only strong forces of foreign marines kept the Nationalist armies out of the foreign settlements in Shanghai. The northern military chiefs, alarmed, had put themselves under the direction of Chang Tso-lin to stem, if possible, the oncoming flood.

The radicalism of the Communists during the northern expedition inevitably produced a reaction. Merchants, landlords, army officers and many other groups who found themselves menaced offered support to conservative leaders in the Kuomintang if they would rid the party of its radical wing. With victory in sight, tension between right and left grew sharper. Chiang Kai-shek became the centre of the anti-Communist movement. In March 1927 Nationalist troops, entering Nanking, looted foreign dwellings, robbed foreigners and killed several of them, until further loss of foreign lives was prevented by the fire of British and U.S. gunboats in the Yangtze river. One effect of this incident was to widen the breach within the Kuomintang.

In the Chinese section of Shanghai, labour unions under leadership of the left wing had risen in a general strike, disarmed police and driven out some of the northern troops. On April 12, shortly after the Nationalist army arrived in Shanghai, Chiang Kai-shek instituted a bloody purge to stamp out the Communists and left Kuomintang elements in the city. The purge quickly spread to other regions under control of conservative military commanders. Chiang then set up a government in Nanking as a rival to the one in Hankow. The irreconcilable cleft between Communists and Nationalists dates from this period.

The Nationalist advance was halted by these internal dissensions, and the party continued to divide. By autumn 1927 the anti-Communist reaction was in full swing, Borodin and other Russian advisers were ousted from Hankow, and in many places Chinese Communists were being hunted down and executed.

In 1928 the Nationalists reorganized under moderate and conservative leaders and with headquarters at Nanking, began a new northward advance. Chiang Kai-shek led, in co-operation with Fêng Yü-hsiang and Yen Hsi-shan. A serious clash with Japanese troops occurred in May in Chinan, and a partial reoccupation of Shantung by Japan followed. In spite of this, however, the Nationalists pushed on and in June entered Peking. Chang Tso-lin was killed by a bomb as he was retiring into Manchuria, and

his son, Chang Hsüeh-liang, succeeded to the command of his forces. Because of Japanese opposition, Manchuria did not formally join the Nationalists, but Chang Hsüeh-liang was given a place on the chief council of the Nanking government. The major armed opposition to their rule having been eliminated, the Nationalists moved the capital from Peking (now renamed Peiping, "Northern Peace") to Nanking and in October set up an administration reorganized to conform to Sun Yat-sen's program, with Chiang Kai-shek as the ranking official.

Events From 1928 to 1937.—In domestic politics the years from 1928 to 1937 were stormy but on the whole witnessed marked progress toward a more stable regime. Throughout them all, the most prominent figure in the central government was Chiang Kai-shek. In 1927 he married Soong Mei-ling, a sister of Mme. Sun Yat-sen, and so, in a sense, strengthened his claim to the inheritance of the leadership of the Kuomintang. Much of the time, moreover, two of his brothers-in-law occupied prominent posts in the central government—T. V. Soong, who proved an extraordinarily able minister of finance, and H. H. K'ung, who had married one of the Soong sisters.

So strong and vigorous a man as Chiang Kai-shek inevitably had his enemies. However, he retained control of the army and, accordingly, continued the dominant leader.

The chief internal movements against the authority of Chiang Kai-shek after 1928 can be quickly summarized. Yen Hsi-shan and Féng Yü-hsiang could scarcely be expected to submit tamely to the leadership of this young arrival from the south. In the summer of 1930 they joined forces against Chiang. By autumn of that year, however, Chiang had vindicated his power against them. The "Young Marshal," Chang Hsüeh-liang, until the autumn of 1931 in possession of the major military machine in the north, continued loyal to Nanking and to Chiang.

More serious was the recalcitrancy of the south and west. Only slowly, and then largely because of the necessity of presenting a common front against the Japanese, did Kwangtung, Kwangsi, Yunnan, Kweichow and Szechwan fall into line with Nanking.

The greatest domestic menace to Chiang Kai-shek and the Kuomintang, however, was the Communist movement. After the purges of mid-1927 the Communist party turned to armed force to overthrow its rival. Only gradually was it able to create armed bands of peasants and deserting soldiers, seize control of inaccessible bits of territory and begin to create soviet districts. It appealed to tenant farmers, landless labourers and others upon whom the existing rural order bore most heavily. Terror was widely used, and persons of property were cruelly dealt with. In essence the movement fed on peasant revolt. By 1930 the Red army had become a sizable force and soviet regions covered large areas in Kiangsi, Fukien, Hunan and Hupeh.

The Nanking government launched five campaigns between Dec. 1930 and Oct. 1933 in an attempt to destroy the Red army and capture the soviet bases. Finally by Oct. 1934 the main Red forces were driven out of their chief base in southern Kiangsi. They executed a long retreat, marching and fighting through most of the southern and western provinces of China, arriving in north Shensi one year later. In the meantime Japan had seized Manchuria and was seeking to detach north China (*see* below). The Communists skilfully employed the rising patriotic sentiment to blunt the Nationalist attacks against themselves, urging an end of civil war and a united front of all parties and armies against Japan. This program appealed especially to the Manchurian troops of Chang Hsüeh-liang who were being used to fight the Communists in north Shensi. When Chiang Kai-shek went late in 1936 to Sian to push the campaign, he was seized by Chang Hsüeh-liang, who demanded the end of the civil war against the Communists, a reorganization of the government with more toleration for the opposition and, above all, a united front against Japan.

Although Chiang Kai-shek was released without publicly acceding and Chang Hsüeh-liang was technically punished, in effect the dramatic incident was the precursor to the easing of the war against the Communists and to the eventual co-operation of the latter in the defense against Japan.

In many ways advance was being registered by the Nationalist government. A better class of official was gradually introduced, partly through the initiative of Chiang Kai-shek. In many districts and in some of the provinces, men with modern training, less venal and with more of the community spirit than the typical war lord, were coming into power. Many felt the importance of improving the conditions of those rural masses who constituted the vast majority of the population. The government had no fundamental program to reform the socio-economic maladjustment in rural areas, however. Government energies were concentrated elsewhere. Education throughout the country was improved, with schools of better equipment and quality and with increasing enrolments. The government, too, became increasingly interested in public health. Previously physicians with modern training had come almost entirely from schools founded by Christian missionaries. Now the state was assuming more of the burden of public health, both by the organization of schools of modern medicine and by community-wide campaigns for the control of disease.

The improvement in internal order must not be exaggerated. Much of it depended precariously upon the life of one man, Chiang Kai-shek. Dissensions among leaders had not been eliminated. Over several provinces even of China proper Nanking exercised no effective control. In the outlying dependencies, only in Sinkiang, in portions of Inner Mongolia and here and there on the borders of Tibet did Nanking exert even a shadow of power. The world-wide financial depression brought embarrassment, especially beginning in 1934 with a marked rise in the price of silver and, accordingly, with a fall in other price levels. In the autumn of 1935 the government felt itself forced to nationalize all the silver and to go officially on a managed currency. Yet nearly every year witnessed some gains. Even those provinces which did not tolerate the interference of Nanking in their internal affairs usually permitted the Nationalist government to speak for them in relations with other nations.

One post office administration and one customs service extended throughout the country. In educational matters practically all the provinces co-operated with Nanking. Painfully and with occasional relapses China was advancing toward unification and a better and more stable government.

For more than two years after 1928 China seemed to be making progress toward emancipation from the "unequal treaties." In 1929 the British returned to Chinese administration their concession in Chinkiang and the next year their concession in Amoy. In 1929 Belgium consented to the cancellation of its concession in Tientsin. In 1928 and 1929 nearly all the western powers formally assented to the resumption by China of its tariff autonomy, followed in 1930 by Japan. On Feb. 1, 1929, accordingly, the Chinese government put into effect a schedule of duties determined by itself. Moreover, effective Chinese control over the customs administration increased. China, too, seemed to be making headway toward the abolition of extraterritoriality. Several of the smaller powers assented to the jurisdiction of Chinese laws and courts over their citizens. In July 1928 the Nanking government announced that all "unequal treaties . . . which have already expired shall *ipso facto* be abrogated" and that it would take immediate steps to end those "unequal treaties which have not yet expired and conclude new treaties." A number of the powers against which China adopted specific measures protested. Eventually several assented, but only on certain conditions. However, Great Britain, Japan, France and the United States, together with some of the smaller countries, held out. In Dec. 1929 Nanking announced that extraterritoriality would come to an end on Jan. 1, 1930, but postponed putting the order into effect pending suitable provision for the trial of cases involving foreigners. The needed regulations were framed and were announced to be operative on Jan. 1, 1932. Before that day arrived, however, events in Manchuria precluded carrying out the plan.

For several years after 1927 the relations of Nanking with Moscow were much of the time either strained or decidedly unfriendly. The Nanking government had been established in an

anti-Communist reaction and could scarcely be expected to look upon the U.S.S.R. with cordiality. The joint operation by Russians and Chinese of the Chinese Eastern railway, in Manchuria, made for irritation. In 1929, indeed, the Chinese dismissed and arrested the Soviet officials associated with the railway. In Jan. 1930 a Russian invasion forced the Chinese to assent to the restoration to the Soviet Union of its former share in the control of the line. The U.S.S.R., moreover, had the sovietized Outer Mongolia in its orbit and appeared to threaten the remnants of Chinese authority in Sinkiang. By the end of 1932, however, Russo-Chinese relations became much more friendly, especially since both nations found common cause in their apprehension of Japan.

Japanese Aggression.—It was from Japan, as it has been suggested, that the greatest external menace arose to the territorial integrity and independence of China. Since the Washington conference the attitude of the Japanese government toward China had usually been one of moderation and restraint.

In Manchuria, however, a serious conflict was brewing. There the Chinese were especially restive under the privileges held by the Japanese. Chinese formed the vast majority of the population, and the legal title of the region was held by China, yet Japan controlled much of south Manchuria through its railways and its leasehold on the Liaotung peninsula, and in other ways compromised Chinese sovereignty. The Chinese began building a series of railroads which would in part encircle the Japanese lines, debouch at Hulutao, a port which the Chinese were developing, and make them partially independent of the Japanese. Chang Hsüeh-liang, the ruler of Manchuria, was disposed more and more to ally himself with Nanking and to sympathize with the Kuomintang and its desire to rid China of foreign control.

The Japanese, on the other hand, had large investments in Manchuria. Because of the rapidly increasing population of their islands and the necessity which they were under of finding markets and raw materials for the industries which were their only relief, they looked upon Manchuria as their life line against national ruin, as a bulwark against the U.S.S.R. and as a source of food, coal and oil in case they should go to war with a naval power. In the summer of 1931 the friction expressed itself in minor incidents. The element in control of the main body of the Japanese forces in Manchuria believed that the time had passed for temporizing and compromise, and on the night of Sept. 18–19, 1931, alleging that Chinese had blown up part of the track of the South Manchuria railway near the city, seized Mukden.

In the next few weeks the Japanese occupied other cities in Manchuria and demolished Chang Hsüeh-liang's power north of the Great Wall. Having destroyed the only effective Chinese rule in Manchuria, the Japanese, compelled to preserve order to protect their own interests and not disposed to annex the region outright, stimulated native leaders, largely Chinese, to set up local governments. Early in 1932 these were organized, with Japanese direction, into a new state called Manchoukuo which on Feb. 18, 1932, declared its independence and called to its head P'u Yi, the last Manchu emperor of China.

Later in the year Japan accorded Manchoukuo official recognition and entered into a defensive alliance with it.

Nanking, unable to offer effective armed resistance to Japan, presented its case to the League of Nations. The League found in it the most difficult crisis which that young organization had yet faced, attempted to induce Japan to withdraw its troops to the zone of the South Manchuria railway, and in time appointed a commission, headed by Lord Lytton, to investigate.

The commission's report, made in the autumn of 1932, in the main found Japan to be at fault and proposed a procedure for settling the dispute which would preserve China's sovereignty. On Feb. 24, 1933, the assembly of the League took action against Japan, recommending a method of effecting an adjustment which Japan would not accept. Soon thereafter Tokyo announced its resignation from the League.

The United States, at times acting in close co-operation with the League, attempted to induce Japan to keep the peace and declined to recognize Manchoukuo. The U.S.S.R., while deeply interested, was not disposed to go to war to keep Japan out of the Russian sphere of influence in northern Manchuria.

The Chinese, powerless to oppose effective military resistance, had at hand a weapon in the boycott. They invoked this at great cost to Japanese trade. The Japanese objected, friction became acute and fighting broke out in Jan. 1932 at Shanghai; in the ensuing warfare Japanese forces laid waste a large portion of the city. The Chinese offered a much sturdier defense than had been expected, but eventually were driven back. Due in part to the good offices of the League, fighting ceased in March 1932.

Chinese anti-Japanese activities continued in Manchuria, largely through irregulars. Chang Hsüeh-liang, for a time with his headquarters at near-by Peiping (Peking), was a source of irritation. The Japanese, too, wished to add the province of Jehol to Manchoukuo. In Jan.-Feb. 1933, Manchoukuoan-Japanese forces occupied Jehol, and Chang Hsüeh-liang, his prestige badly damaged, soon resigned and left for Europe. When he returned, it was to a post in Hupeh and then in Shensi. In April 1933 the Japanese, annoyed by raids from south of Jehol, advanced within the Great Wall. The Chinese were forced to withdraw and on May 31 Nanking found it advisable to enter into a truce, setting up a demilitarized zone south of the Great Wall in the northeastern part of the province of Hopei. Strangely enough, however, in all this time war was not officially declared and regular diplomatic relations were maintained between the two governments. The truce of May 1933 established a *modus vivendi* which was practically a treaty of peace and which tacitly (although not explicitly) acquiesced in the Japanese occupation of Manchuria. The articulate among the Chinese, however, remained unreconciled to the existence of Manchoukuo. Moreover, for a number of years only two foreign powers besides Japan, Italy and the small Central American El Salvador, formally accorded the new state official recognition.

Japan, however, persevered in consolidating its position in Manchoukuo. It acted against banditry and entered upon a vast program of railway building which opened up more of the land and connected it with Korea. In 1934 P'u Yi was officially crowned monarch of the new state.

After long negotiations, moreover, Japan obtained the sale of the Russian interest in the Chinese Eastern railway and thus eliminated the last legal trace of the former Russian sphere of influence.

Japan was not content with confining its control of China to regions north of the Great Wall. In the spring of 1934 a pronouncement from Tokyo in effect declared all China to be a Japanese preserve in which no power could take important action without the consent of the island empire. In 1935, moreover, Japanese forced the withdrawal from Hopei and Chahar of any officials and armed forces and the disbandment of any organization which might prove unfriendly to Japan. The provinces of Hopei and Chahar passed partly into Japanese control, and Suiyuan, Shansi and Shantung were threatened. Chiang Kai-shek dared not offer open opposition for fear of bringing a Japanese avalanche upon his head.

In July 1937 what proved to be a life and death struggle broke out between China and Japan. The opening incident was a minor clash between Chinese and Japanese troops not far from Peiping on the night of July 7. The conflict soon ceased to be localized. The Japanese came to feel that since Chiang Kai-shek and the Nationalist government would not yield to their wishes they must be eliminated. To the Japanese, the rising tide of nationalism in China, directed, as much of it was, against them, had become intolerable. Governments, so they held, must be set up in China which would co-operate with Japan.

The Chino-Japanese War, 1937–45.—The war, which remained undeclared until Dec. 9, 1941, may be divided into three phases—a period of rapid Japanese advance until the end of 1938, a period of virtual stalemate until 1944, and the final period when United Nations counterattack, principally in the Pacific and on Japan's home islands, brought about Japan's surrender.

In July 1937 the Chinese people were determined to resist further Japanese aggression. Practically all regional military

political groups rallied to support the National government and Chiang Kai-shek in their decision to oppose Japan by every means. The Communists, who had urged a united front against Japan since 1935, pledged their support and put their armies nominally under command of the government. From a strictly military point of view, however, Japan was so much better prepared than China that its armies achieved rapid initial success.

Within the course of two years Japan obtained possession of most of the ports, of the majority of the chief cities as far west as Hankow and of the larger part of the railways. Peiping and Tientsin were occupied in July 1937. After fierce fighting, the Chinese armies were driven out of the Shanghai area by the middle of Nov. 1937. Nanking fell in mid-Dec. 1937. The capital was moved west to Hankow. The Japanese followed and took that city in Oct. 1938. In the same month, the Chinese lost Canton. The Japanese pressed northward and westward from Peiping along the railway lines into Shansi and Inner Mongolia. They dominated Shantung. They took possession of the Peiping-Hankow, the Tientsin-Pukow and the Lunghai railways and of the lines in the lower part of the Yangtze valley. They had complete command of the sea. Always superior in the air, before many months they had all but destroyed the Chinese air force and bombed Chinese cities at will. The loss of life, particularly to Chinese, both soldiers and civilians, was enormous.

Yet the Chinese did not yield and the war was prolonged far beyond Japan's expectations. Chiang Kai-shek moved his capital to Chungking, in Szechwan, at the western end of the difficult Yangtze gorges. Much of China's leadership migrated to the far west, to Szechwan and Yünnan. In Free China, they prepared for prolonged resistance. In occupied China Japan was unsuccessful in inducing many Chinese of standing to take office in the governments which it endeavoured to set up. Even there Japan's control was confined to the cities and the railway lines; outside these it was challenged, often successfully, by guerrilla bands which professed allegiance to the Nationalist government. The Communist regime was particularly successful in using guerrilla methods to resist Japan. The rapid Japanese advances broke down the established patterns of politico-military control. Communists troops and organizers moved into the vast rural areas behind Japanese lines. They organized village self-defense units, created local governments and expanded their own armies, the 8th route army operating in the mountains and plains of north China and the new 4th army in the lower Yangtze valley.

During the stalemate phase of the war, beginning in 1939, Japan tried to subdue Chinese resistance by the slow strangulation of blockade. China's main seaports were occupied, from the south to the north. In at least one, Foochow, the occupation was only intermittent, but in most of them it was continuous. When, in 1940, France fell to the Germans, Japan took the occasion to advance in French Indochina and to seal access to Free China by the railroad which led from the coast to Kunming (Yünnanfu) and by crude highways from the Indochinese coast to the interior. For a time Japan induced the English, fighting as they were with their backs to the wall, to close the difficult road which led from Burma to Yünnan. After a time the English reopened the road. Then, following years of increasing tension, came the sudden outbreak of war, precipitated by the Japanese attack on Pearl Harbor (Dec. 7, 1941), between the United States and Great Britain on the one hand and Japan on the other.

Japanese, taking advantage of their preparedness on land, sea and air and of their favourable geographic position, quickly made themselves dominant on the coasts of east Asia. Their capture of Hong Kong and of Burma in 1942 shut doors by which some goods had moved in and out of Free China.

The only routes which now remained to connect the fighting Chinese with their friends abroad were the long and difficult roads across Sinkiang and the air passage from Assam to Free China. Over the latter, freight and passengers were conveyed by heroic airmen, and that in spite of the perils of high altitudes and of Japanese planes. Through the venality of Japanese officials and the skill of blockade runners, some goods trickled through the Japanese lines along the coast.

During the war of endurance China was divided into three regions—Free China under control of the Nationalist government, Communist China and the regions occupied by Japan. The regimes in each area were pitted against the other two.

Nationalist China had serious economic and social problems. The relatively backward western provinces, with almost no modern industry or transport facilities, were strained to support the huge armies and the government. Free China was crowded with refugees and some of its cities were mercilessly bombed. The shortage of manufactured goods and the costs of war brought on inflation which was intensified by the government's fiscal policy and which caused great hardship to troops, government workers, teachers, wage earners and students. It encouraged hoarding, speculation and graft. The army, unable to take the offensive against the superior Japanese forces, steadily deteriorated. Graft became widespread among the officers, while the undernourished conscripts no longer had much will to fight.

In schools and colleges shortage of books and equipment, malnutrition and attempted regimentation by government thought-police all had a deteriorating effect.

The government, too, was deeply affected by the war. It had lost its industrial and financial base in east China and the flower of its armies. The strong public support it enjoyed during the early years of resistance waned and turned to apathy or hostility. This was the result of many factors. The government was blamed for the ills of inflation, corruption and heavy taxation. The strains of war tore at the united front.

When the Communists began to reappear as rivals rather than subordinates, the government retaliated with repressive measures which it applied also to other groups. Essentially an authoritarian regime, it tended to become more repressive and less efficient as the war dragged on. Yet with all these difficulties, Free China under Chiang Kai-shek's leadership refused to surrender or negotiate with Japan.

The scattered areas controlled by the Communist party and its armies grew during the war until near the end they covered large parts of north and east China. In these "border regions" and "liberated areas" the regime was, by nearly unanimous report, popular with the people.

This was partly the result of economic and social reforms which bettered the conditions of the peasantry and partly the result of the system of local government which encouraged wide participation of the public through mass organizations even though control was held firmly by the party. The army was also popular because of its good discipline and close relations with the common people upon whom it depended for existence.

During the stalemate period relations between the Nationalists and the Communists were embittered by many military clashes for which each side blamed the other. The Communists did everything possible to strengthen themselves, while the government tried to keep them confined by blockade and other means. In effect the civil war was merely submerged, after 1938, in the larger war with Japan.

In the occupied regions Japan tried to win support and lessen its military burden by setting up a puppet regime at Nanking (1940). To head this, it obtained Wang Ching-wei, an erstwhile intimate companion of Sun Yat-sen, who professed to be carrying on the latter's tradition. Japan also went through the motions of restoring to Chinese administration the French concession and the international settlement in Shanghai, for it had taken these over after the attack on Pearl Harbor.

Yet Japan was no more successful than earlier in inducing many Chinese of ability and integrity to serve in these administrations. Obviously, too, no important step could be taken by these regimes without the approval of the Japanese authorities.

In the last phase of the war, from early 1944 to Aug. 1945, some help was beginning to come to China from the outside, chiefly from the United States. Aeroplanes and various kinds of war *matériel* were being flown from India over "the hump," as the mountain barrier was called. Chinese pilots and mechanics were being trained. No longer could the Japanese bomb Chinese cities at will. [illegible]

Chinese planes. Americans were also training and equipping in India Chinese forces which had taken refuge there after the fall of Burma. Yet the main theatre of war was far from China, whose armies by then were too debilitated to play an important part in the final campaigns

The Nationalist government had been seriously undermined by seven years of war and inflation, while Communist strength had grown. As Japan withdrew divisions to fight on Pacific islands, the Communist armies were able to move in and organize more "liberated areas." The danger of fratricidal war after Japan's defeat became obvious. Patriotic Chinese of all parties hoped to find some way to restore national unity and avoid a ruinous civil war. The U.S. government was drawn into China's domestic crisis since the United States provided the main external supports —financial, military and diplomatic—for the Nationalist government and since the U.S. was eager that China should take a place after the war as a stabilizing influence in the far east. In various ways United States representatives in China tried to bring about a reconciliation between the Kuomintang and the Communists. A fundamental difficulty—besides the bitter distrust and intransigence of both Chinese parties—lay in the United States' position of trying to mediate between them while supporting one side, the Nationalists, as the government of China.

CHINA AFTER WORLD WAR II

Civil War.—Within five years of the victory over Japan the Nationalist government had been driven from the mainland by the Communists, who then became masters of the country. Japan's defeat set off a struggle for control of occupied China extending from Manchuria in the north to Canton in the south. Nationalist troops, transported by the U.S. army air force and navy, were able to take over key cities and most railway lines in east and north China. But Communist troops, moving out from their guerrilla bases, occupied much of the hinterland in the north and in Manchuria. The stage was set for full-scale renewal of civil war.

For more than a year the U.S. government attempted, through its ambassador, Patrick J. Hurley, and then through Gen. George C. Marshall, to mediate and prevent this conflict. During Jan. and Feb. 1946, it appeared that agreements laying the basis for peace had been reached. On Jan. 10 the Nationalists and Communists concluded a cease-fire agreement to be administered by a tripartite committee (Kuomintang, Communist and U.S.) which would send out truce teams to stop conflicts that flared up. A Political Consultation conference representing all parties, meeting Jan. 10–31, worked out plans for an interim coalition government to function until a new constitution should be adopted by a representative national assembly. On Feb. 25, 1946, a military reorganization plan worked out with the help of General Marshall, to merge and consolidate the hostile armies, was agreed upon by representatives of the government and of the Communist party. Within a few months, however, these agreements were undone. During all of 1946 the U.S. government, acting through General Marshall and his aides, strove for peace. The hostility, ambition and distrust of both Chinese parties made peace impossible.

The civil war was fought out from 1946 to 1950. In that period the great strategic advantage of the Nationalists was reversed. During 1946 and early 1947 they succeeded in taking most of the railways and in recapturing important cities in the north. As Soviet troops withdrew from Manchuria the Nationalists sent in their best armies to try to hold the vital railways and industrial centres. But they were overextended. Communist forces, retrained and re-equipped with Japanese arms, gradually shifted from guerrilla warfare to large-scale offensive campaigns. In 1948 they turned the tide, destroying the Nationalist armies in Manchuria and winning impressive victories in north China. By the end of the year the Nationalist government was in desperate straits. Its armies were disintegrating. Inflation was destroying the economy. The Kuomintang was torn by factional strife. The public was withdrawing its support of the regime.

In 1948 the Communists began a southward march. They captured Nanking, the Nationalist capital, on April 24, 1949; the substitute capital of Canton, on Oct. 15; then Chungking, the wartime capital to which the government returned for final refuge, on Nov. 30. On Dec. 8, 1949, the government declared Taipei in Formosa to be the National capital.

Communist Regime.—During 1949 the Communists laid the foundation for a national government. In September the Chinese People's Political Consultative conference, a body having the appearance of a constitutional convention, met in Peiping to establish a new government. The conference included representatives of many parties, professions, organizations, and ethnic minorities, but selection was determined by the Communist party, which dominated the gathering behind the scenes. The climax of its meetings was the announcement of the establishment of the Chinese People's Republic on Oct. 1, 1949.

The Central People's government of the People's Republic of China was established at Peking (renamed by the conference). While having the appearance of a coalition government, it was essentially a Communist dictatorship.

Government was only one of the agencies employed by the Communist leaders to control the country and carry out their policies. Other agencies included the party itself, numerous mass organizations and the armed forces. The Communist party, a highly centralized and strongly disciplined organization, had from 6,000,000 to 7,000,000 members in the early 1950s. Its central committee, or a smaller group within it, determined party policy, carried out by a network of regional, provincial, municipal and lesser committees. The party structure paralleled and party officials controlled each level of the government, of the army and of the mass organizations. The rank-and-file members provided the motive force for carrying out the party's will in factories, villages, street associations and army units throughout the country. After coming to power the party established many types of mass organizations or extended those it had previously created. Associations of peasants, youth, women and labourers enrolled millions or scores of millions of members. Every profession and occupation was organized. Each of these centrally controlled bodies served as an agency to mobilize support for the regime and its programs. At the same time they provided the Chinese people with greater opportunity for participation in government, particularly local government, than ever before.

The party, through the government, established a monopoly of all organs of information—radio, press, motion pictures, etc.—and the entire educational system. All coercive bodies such as the army, the police and the courts came under its control. The government did not hesitate to use terror, including widespread executions and forced labour, to eliminate or control potential opponents. It was through these means that the new regime, with a large measure of popular support, was able to unify the country more completely than any other had done since the height of Manchu power.

In foreign policy the regime was firmly in the world Communist camp. The government was quickly recognized by the Soviet Union and its satellite countries. A treaty of friendship, alliance and mutual assistance between the People's Republic of China and the Soviet Union was signed in Moscow on Feb. 14, 1950. It linked the two countries in a defensive alliance. By the terms of a supplementary agreement, the U.S.S.R. promised to transfer to the People's Republic of China before the end of 1952 all its rights in the Chinese Changchun railway (the former Chinese Eastern and South Manchuria railways) and to withdraw its troops from Port Arthur and turn over the naval base to China's control; Dairen (Dalny) was also to be returned. The U.S.S.R. also extended a five-year credit of U.S. $300,000,000. Subsequent treaties and agreements bound the two countries closely together. Communist China's entry into the Korean conflict toward the end of 1950 tightened this alliance and tended to isolate China from the non-Communist world. The balance of China's foreign trade shifted from Japan and the west to the Soviet Union and its satellites.

The non-Communist governments of the world were divided over the issue whether to recognize the new Chinese government

or continue to deal with the Nationalist government on Formosa. Burma, India, Pakistan, Indonesia, Sweden, Denmark, Finland and Switzerland quickly established relations with the new government. Great Britain and certain other countries offered recognition, but the Communist regime made no effort until 1954 to establish relations. The question which government should represent China in the United Nations was also controversial.

Tibet was brought back under Chinese control through a military campaign beginning in Oct. 1950 and through negotiations during April and May of 1951. The Central People's government promised Tibet "national regional autonomy under the unified leadership of the Central People's Government" but took over the country's defense, communications and external relations. The agreement was signed on May 23, 1951, in Peking and was ratified by the dalai lama in October. In a treaty between India and China signed April 29, 1954, India recognized China's full sovereignty over Tibet and gave up certain privileges previously acquired there by Great Britain.

After winning control of the country, the Communist regime launched a series of nation-wide reforms which attempted to refashion nearly every aspect of Chinese life. Here only a few may be described. Of fundamental significance was the land redistribution program. In this the regime undertook to expropriate the land of all landlords and of "opponents of the state" and distribute it to farm labourers, tenants and poorer peasants. Within a few years, throughout a territory larger than Europe, ownership of land was redistributed and landlords were eliminated as an economic class. This was only the first step toward collectivization. Other intermediate stages were mutual aid teams and agricultural co-operatives, which were gradually developed on an ever expanding scale throughout the land. Marketing and distribution of most of the products of Chinese agriculture was brought under co-operatives and state trading companies. These and other measures were designed to increase greatly the nation's agricultural output and place it at the service of the state for its program of economic development.

China's economic development was planned and controlled by the state. The first several years after 1949 were devoted to rehabilitation and to establishing the mechanism of economic controls. Communication facilities were restored, inflation was halted and state banking and state trading companies were established. The war in Korea prevented much new capital construction except of railways and flood-control systems, but in 1953 the government launched the first five-year plan and announced a "high tide of construction" to transform China from an agricultural to an industrial country. Visitors to China in 1954 and 1955 reported impressive results.

The Communist regime actively extended education, which was brought completely under state control. Schools and colleges operated by western missionaries were confiscated. In the revised system emphasis was laid upon expanded educational facilities, ideological uniformity and technical training. A central purpose of the new system was to bring education within the reach of all workers and peasants. Mass education to eliminate illiteracy was pushed vigorously. Elementary education was to be available to all children. Teachers were retrained through "ideological remoulding campaigns," and new textbooks, much influenced by Soviet counterparts, were produced. Secondary and higher education became increasingly technical in order to train engineers, agronomists, medical personnel and technicians needed for the country's reconstruction.

The emancipation of women from their inferior position in the old society was announced as another aim of the Communist regime, carrying forward a movement which had been developing during previous decades of the 20th century. Legislation strengthened women's rights in property ownership, employment and health insurance. The marriage law, promulgated in May 1950, made child marriage and concubinage illegal, and stressed the right of young women to choose their own marriage partners. Women were given franchise equal to that of men.

During 1953–54, elections were held throughout China for "people's congresses" at village, county, municipal, provincial and national levels. To prepare for elections a population count was made as of June 30, 1953. According to official announcement, China's total population was found to be 601,938,035 (this included 7,591,298 for Taiwan and 11,743,320 estimated for Chinese abroad). On Sept. 20, 1954, the new National People's congress adopted a constitution of the People's Republic of China, the first constitution since China came under Communist control.

Nationalist Government on Formosa.—The Nationalist government meanwhile maintained itself on Formosa, which had reverted to Chinese control upon Japan's surrender in Aug. 1945. When the island became the government's last refuge late in 1949 it was necessary thoroughly to reform the inefficient, "carpet-bag" administration which had operated there during most of the civil war period. The Kuomintang party was reorganized with a view to its revitalization. The government bureaucracy, superimposed upon the provincial administration, was reduced and rationalized. The armed forces which had fled from the mainland were reorganized and, with help from a United States military mission and large U.S. financial grants, were revived into a more effective fighting force to defend the island and, according to Nationalist hopes, to lead in a reconquest of the mainland. In these efforts to establish a secure base Chiang Kai-shek took the lead as head of the Kuomintang, president of the republic and commander in chief of the armed forces. His power within the regime became even more absolute than before.

An attempt was made to provide Formosa with an efficient administration having due regard for the welfare of the people. This was necessary in order to restore confidence in the Nationalist government both at home and abroad. Elections in 1950–51 for magistrates, mayors and councils introduced a measure of local self-government. (The councils were given only advisory, not legislative, power.)

In the civil service the proportion of Formosans, especially in higher positions, was markedly increased. The former Japanese educational system was completely reorganized and extended so that more than 80% of children of elementary school age were in schools by 1952. Facilities for secondary and higher education were also greatly expanded.

The island's economy was brought back to the productive levels of the prewar Japanese administration or improved. During four years, 1949–53, the Nationalist government peacefully carried out a land reform program including reduction of land rents to 37.5% of the yield, sale of government land to cultivators, and government purchase of landlord's land and sale to tenant cultivators. As a result 5,800,000 ac. of land were transferred to tenants, and the percentage of Formosa's farmland cultivated by owners increased from 50.5% to 75.4%. With help of the Joint Commission on Rural Reconstruction, composed of Chinese and Americans, significant improvements were made in irrigation, cropping methods, animal husbandry, organizing of farmers' associations and agricultural extension. But the island's economy had to support the Nationalist government, armed forces numbering 500,000 and about 1,000,000 refugees from the mainland. Only with extensive economic aid from the U.S. was that possible. Inflationary pressures were held in check with greatest difficulty.

On April 28, 1952, the Nationalist government on Formosa and the government of Japan signed a separate peace officially ending the war which had begun in fact on July 7, 1937. Yet the two Chinese political regimes—Nationalist and Communist—which had been at war most of the time since 1927, confronted each other across the Formosan strait in a continuation of the contest for support of the Chinese people and the nations of the world.

ETHNOLOGY

Two forms of early man are found in China: chronologically, the giant ape (*Gigantopithecus blacki*) and Peking man (*Sinanthropus pekinensis*). The existence of the first was evidenced by three teeth found in south China and corroborated by some larger specimens of the Java man (*Pithecanthropus erectus*). Remains of the Peking man were much more abundantly found in a cave southwest of Peking. Most original remains of the Peking man disappeared in the China sea somewhere en route either to Japan or to the Philippines during World War II. The authenticity of the giant ape was in dispute in the mid-1950s, and the conditions of its existence remained unknown. The Peking man had tools of the Old Stone Age type, including crude flints, bone and ornaments such as beads and perforated teeth and shells. It is doubtful that Peking man was ancestral to modern Chinese, for most or all of his points of resemblance with the Chinese are also shared by other living races, notably those of Europe.

Early Origins.—While there is evidence in Chinese myths and tradition, early history and archaeology that the original Chinese came to China via Sinkiang (Chinese Turkistan), there is also a likelihood that they might have reached the continent from the north, via Mongolia. H. L. Movius, Jr., based the latter contention on the following grounds: (1) The Old Stone Age implements found with the Peking man are of the chopper type, different from all Old Stone Age tools found in Europe and elsewhere. (2) The Old Stone Age tools found in the Ordos region of Mongolia seem to have much in common with those of the Yenisei-Baikal region of Siberia, on the one hand, and with the pebble tools of the type used by the Peking man.

There is much more abundant evidence of New Stone age developments among the Chinese in north central China, in the basin of the lower Hwang-ho, the major home of the prehistoric Chinese. The first part of this development was characterized by polychrome pottery of two general varieties: a hand-made red and design-painted kind and a coarser, gray, unpainted ware. The second part, probably overlapping somewhat with the former, was characterized by a kind of all-black ware, fine, thin, wheel-turned and burnished. With this ware was also found a white variety made of kaolin. Both parts of these cultural developments were associated with other items. Coexisting with polychrome pottery were agriculture, stock raising, houses with roof entrances and possibly some metal. The most outstanding things associated with the black wares were the walled cities which remained an important Chinese culture trait throughout their later history.

The bronze culture which followed that of the black wares marked the beginning of Chinese written history. The inscriptions on the many hundreds of oracle bones uncovered in Anyang in the same general area of the Stone Age cultures depict a civilization with dynasties, commanding armies of 1,000 to 5,000 men, great subterranean tombs, horse teams yoked to spoked chariots, silk, clothes with sleeves, animal and human sacrifices, writing and bronze vessels and implements made both with moulds and by the melted-wax method. This culture developed at least 1,000 years after the rise of its Sumerian and Egyptian counterparts, but within a short period it seems to have achieved equal splendour, with a characteristic Chinese colouring and style. (See *Archaeology*, above.)

Influences on Other Peoples.—From north central China the Chinese extended their influence over the rest of China, including not only the original 18 provinces but also Manchuria and Formosa, while keeping and amplifying their own peculiar cultural integrity and form remarkably well. It is highly probable that racially the Koreans and at least some Japanese and Indochinese were of Chinese origin.

The racial influence of the Chinese on their other neighbours is less pronounced, although they have continuously absorbed some of the aboriginal peoples in China as they replaced them as well as invaders from outside, notably the Manchus, who ruled China for nearly 300 years. Yet in spite of this history of mixture, the modern Chinese as a whole show a higher degree of homogeneity than the peoples of Europe. The skin colour is generally light yellow, fair in some regions and brownish in others. The hair is usually black and straight, while occasionally a strain of waviness is present. The Mongolian eye fold is conspicuous as with all Asian peoples. The stature is generally medium, but in a few provinces such as Fukien and Hupeh it is not unusual to find adult men more than six feet tall. The head form ranges from long to broad, while the width of the nose is medium.

The cultural influences of the Chinese over their neighbours as well as the country's intruders have been more spectacular than their physical absorption of them. The Japanese received from the Chinese the entire Confucian ethics, although keeping their own variety of ancestor worship and political organization, and the Chinese version of Buddhism. The Korean family relationship and court manners and organization were practically copies of those of China. In much of Indochina the same imitation occurred. The styles of clothing and hairdress of modern Japan and Korea were those prevailing in China about T'ang times, while the premodern official garments and paraphernalia of the several states in Indochina were those prevailing in China up to the 17th century. The most extraordinary Chinese influence on Japan and Korea was linguistic. Both the Japanese and the Koreans borrowed the Chinese written language after, probably, the 5th century A.D. Although the Japanese and the Koreans each later acquired an alphabetic system of their own, even today they continue to cling to the Chinese characters to parallel their phonetic scripts.

Regional Differences.—There are certain obvious regional differences in China, not only in topography and climate but also in culture of the inhabitants. China south of the Yangtze is subtropical; in the Hwang-ho region and north of it, it is frigid, while in that region which lies between it is temperate. In the south the rainfall is from 40 to 75 in. annually, whereas in the

north it ranges from 25 to 10 in. Topographically the variation is equally extreme. In south China, parts of north China and especially west China are many hills and mountains. Most of the plateau of Tibet comes to three miles in elevation, with many peaks reaching five miles. On the other hand, east China is close to sea level, being an alluvial plain. In Sinkiang the oasis of Turfan is as low as 928 ft. below sea level.

China can be differentiated into at least three agricultural regions. In the south and the southwest rice is the principal crop, and the average farm or area of cultivation is three acres or less. In the north, inside the great wall, the principal crop is wheat, and the usual size of a farm is about five acres. In Manchuria in the northeast, the average farm is much larger—about 15 ac. or more—and the principal crops are corn and sorghum.

Historically there have been many differences between the northern and southern peoples. More southerners than northerners have participated in China's political, intellectual and artistic life. The relatively few Chinese who migrated after about 1750 to the south seas and the west were practically all southerners. Modern revolutions in China from the T'ai P'ing to the Communist were all led by southerners. For these reasons, the southerners in China have been described as more progressive and the northerners more conservative, the former as more urban, the latter more rural.

The differences among the different regions of China, however, are overshadowed by the many basic similarities. Throughout China persist the same pattern of family and filial piety, the practice of ancestor worship and the observance of the same major festivals, as well as similar marriage and funeral practices. Even the diversity of dialects has been much exaggerated. In all there are probably not more than eight mutually unintelligible dialects, seven of which are spoken in the narrow coastal belt stretching from Shanghai to Canton. The rest of China speaks one variety or another of Mandarin, with regional differences not greater than those, for example, between Chicago, Ill., and Houston, Tex. Furthermore even the mutually unintelligible dialects are practically identical in grammar. Only one written language prevails among all literate Chinese regardless of geographical origin.

Religion.—For untold years writers have spoken of the Chinese as having three major religions: Confucianism, Taoism and Buddhism. This is a misconception. Individual westerners usually not only adhere to one faith but also to one denomination or even to one branch of that denomination. Members of different churches of the same sect have a sense of rivalry. Such phenomena are unknown to the Chinese. The average Chinese tends to have something to do with any or all religions but adheres exclusively to none.

The most universal system of belief in China is ancestor worship. First, it is a part of the filial duty of sons to provide for their parents before and after death, for the dead are believed to have the same needs as the living. Second, like the father-son relationship within the family, the relationship between the departed ancestors and their living descendants is also reciprocal. The conduct of the living affects the welfare of the dead, and the actions of the latter in the spirit world continue to help the living. Many Chinese folk tales and novels depict this belief. Third, the interest of the departed ancestors is largely confined to their own lineal descendants, just as the duty of worship on the part of the living is confined to the lineal ancestors. It is because of ancestor worship that the Chinese construct elaborate tombs and graveyards for the dead. Here again the elaborate tombs and graveyards are not merely for the comfort of the dead. By means of *feng shui* ("wind and water" or geomancy) the Chinese arrange the burial grounds of their dead so that the graveyards will promote the prosperity of and ensure good luck for the descendants.

Ancestor worship is, however, part of a wider belief system of the Chinese. The departed ancestors are spiritual beings closest to the living descendants, but each descendant is also affected by a tremendous hierarchy of nonancestral gods. In its bare outline this spiritual hierarchy is not dissimilar to that of the traditional Chinese government. At the very top is the Supreme Ruler of Heaven and his ministers and their assistants. In the middle are the judges who scrutinize individual merit and demerit to mete out reward or punishment. Then there are the local gods, temples for whom are found in nearly every Chinese village and town. In addition there is the western paradise which seems to have come to China by way of Indian Buddhism. It is in this hierarchy of gods that Confucianism, Taoism and Buddhism find their places. The scholars of China studied the Confucian classics assiduously and raised controversies over them, just as a few learned monks and philosophers also elaborated and discussed the Buddhist scriptures and the essential meaning of the original teachings of the Indian holy man. But to the ordinary believing Chinese, Confucius and his many disciples, Buddha and his many early followers, true or fancied, as well as the many spirits of Taoist origin, were merely intermediary between the Supreme Ruler of Heaven and man. In fact, it is not unusual to find, in many public prayer meetings called to deal with emergencies such as a drought, earthquake or epidemic, the tablets of Mohammed and Jesus Christ placed side by side with those of Confucius, Buddha and Lao Tzŭ (Lao-tse; alleged founder of Taoism), all in a position subordinate to that of the Supreme Ruler of Heaven. In such a prayer meeting, the officiating priests can literally invent any variety of god as they see fit, with no danger of being questioned by the people who provide their support.

The essential character of the Chinese approach to religion is polytheistic, as contrasted with the monotheistic western approach. The latter approach maintains that one and only one God is true and all others are false and therefore must be eradicated and their believers either won over peacefully or forced to change their creed. To the Chinese, however, gods may be higher or lower to one another, more or less powerful than one another, but they coexist, and there is no question of the followers of one group of gods being committed to the transformation or the annihilation of believers in other kinds of deities. Hence theological elaboration for purposes of strengthening a given religion and missionary activities for its spread are as characteristic of the western ways of religion, including Mohammedanism, as they are atypical of the Chinese. Since western forms of belief centre in one God, the magical arts such as horoscope and divination tend to have no place in the regular churches and remain as personal predilections of the relative minority. On the other hand, gods being many and often strange, the Chinese find it necessary to resort, as a matter of regular and formal religious practice, to horoscope, divination and many other similar practices to ascertain the wishes of the gods or to ensure their good graces for private purposes. For the same reason, Chinese Moslems, although they number several million, concentrated in the northwest but also scattered in different parts of China from Yünnan to Manchuria, are described by western observers as not fanatical at all. Mohammedans who served as officials in the Chinese imperial court used to worship at the Temple of Heaven with the emperor, and Mohammedan inhabitants in many parts of the country take active part in rain pleading and other pagan ritual parades. This is why Christianity failed to gain a substantial foothold in China. It is obviously difficult for the average Chinese with his particular religious and cultural background to commit himself irretrievably to one God and forget about all others. Most Chinese Christians, to please their parents, will have no compunction in undergoing two marriage ceremonies, one Christian and one pagan, or in having duplicate funerals for their parents in the same manner. This is probably also why, of the less than 1% of the Chinese population which was converted to Christianity, 90% were Catholics and 10% Protestants. Catholicism, with its many saints, elaborate ritual and a purgatory from which the suffering souls can be raised by the merits of the living, is more in consonance with the Chinese religious orientation than Protestantism.

Non-Chinese Groups.—The greatest concentration of aboriginal tribes in China is in the southwest. Tribal peoples are also found in smaller numbers in the extreme southern provinces such as Kwangsi, Kwangtung and Hainan Island and central provinces such as Hunan. The ethnological classification of these peoples has never been clear. Tribally they are known by such

names as the Chung Chia, Miao (Miaotsze), Kachin, Keh-Lao, Loi, Lolo, Yao, Mo-so, Min Chia, etc. One linguistic analysis divides them into three groups, Lolo, Shan and Miao; another into Mon-Khmer, Shan and Tibeto-Burmans. But linguistic affiliation is no assurance of extensive cultural connection. In fact, some of these groups, notably the Min Chia who inhabit western Yünnan, were so assimilated into the Chinese way of life that they became more Chinese than the Chinese. Others, such as some of the Lolo, in the Yünnan-Szechwan-Tibetan border region, maintained their tribal entity so exclusively that Chinese who entered their area unprotected were captured as slaves. The largest of these groups is probably the Miao, which is divided into several branches. The smallest is probably the Mo-so. Some of these are also more closely related to the peoples of Thailand, Burma and Indochina than to the Chinese. In all probability, the aboriginal groups in southwest and south China were the original inhabitants of the continent and were driven out or replaced by and amalgamated with the Chinese, much like the American Indians with reference to the Americans and the Ainus with reference to the Japanese.

In the north and northwest, other non-Chinese groups either predominate or are present in large numbers. The Mongols in Inner Mongolia have become largely assimilated to the Chinese, but those in Outer Mongolia maintain their tribal entity as well as religious hierarchy. In the Manchurian-Siberian border, a certain number of Tungus tribes live. They are more closely related to the aboriginal tribes in Siberia than to the Mongols. In the northwest, in the province of Sinkiang (Chinese Turkistan), many Arabs, Turks, Uighurs and Kazaks live side by side with their Chinese neighbours, both Mohammedan and non-Mohammedan. Lastly, the Tibetans located south of Sinkiang and west of Yünnan maintained their cultural entity and political semi-independence for many centuries. They and the Mongols to the north share the same branch of Buddhism, namely Lamaism, and the highest religious authorities in Mongolia acknowledge the nominal supremacy of the religious ruler of Tibet. When possible, from time to time, many pilgrims found their way from Mongolia to Tibet. Culturally the Tibetan family is one of the three examples in the world where polyandry prevails. The Tibetans have for many years been the object of attempts at domination or infiltration by the British, the Russians and the Chinese, with the latter claiming nominal suzerainty over the territory. By the mid-1950s the Chinese Communists had undoubtedly obtained more complete control over Tibet as a whole than any of the preceding powers.

In general a majority of the non-Chinese groups are agriculturalists, with the exception of the Mongols in the north and a few groups in the northwest. A majority of them speak some Chinese dialects. Among the illiterate there is the tendency to use Chinese written characters for amulets, a practice they share with the illiterate Chinese. The Lolos are said to have invented a sort of phonetically based system of writing extracted from the Chinese written characters. Physically, all of the non-Chinese peoples, except a few Caucasoid groups in Sinkiang and a small group of Jews in Honan, north China, are varieties of the Mongoloid division of mankind.

See K. S. Latourette, *The Chinese: Their History and Culture*, 3rd ed. (New York, 1946); F. L. K. Hsu, *Under the Ancestors' Shadow* (New York, 1948). (F. L. K. H.)

THE PEOPLE AND THEIR CIVILIZATION

Introduction.—China during the 20th century experienced the most momentous transformation in its history, one affecting every aspect of life: economic, social and political, intellectual, ethical and cultural. Changes were at first sporadic and unco-ordinated, the automatic result of infiltration of alien ideas or modifications by way of goods and techniques imported from the occident. Then under the modern-minded Nationalist government and particularly under the Communist regime there occurred a purposeful, co-ordinated remoulding of the society and economy and a systematic attempt to refashion the habits and even the ethics of the entire people.

China's traditional civilization—over the centuries and millenniums—was essentially indigenous, and it was continuously developing and elaborating. It has never been static and it has intermittently absorbed cultural contributions from abroad. Yet because of its remoteness from other centres of high civilization and because of difficult geographical barriers, the Chinese developed their civilization in relative isolation. Furthermore, in comparison with their non-Chinese neighbours, they possessed a highly sophisticated culture. As dispensers of civilization to surrounding peoples, the Chinese developed a strong sense of superiority. As a result of these factors—the long, continuous and somewhat isolated development of a highly elaborated civilization and the strong cultural pride—there was a powerful resistance to change when this ancient culture was brought into active contact with the entirely different civilizations of Europe. Throughout the 19th century the European conception of the Chinese was of a people immobile, uniform, unchanging and virtually unchangeable. During the 19th century European culture affected little more than the fringes of China and its external political framework. Its influence later, however, began to penetrate to the very foundations of Chinese civilization, bringing about changes in the social and economic fabric, and in the traditional philosophy and ethical outlook of the people, of greater significance than the more dramatic changes in the political sphere. The ultimate effects on the structure of Chinese society of the alterations in its material environment and on the Chinese mind and character of the flood of new ideas, at once disintegrating and liberating, are beyond prophecy, but no generalizations can be valid which do not allow for the great vitality and adaptability of the people. In the consideration of the various aspects of Chinese life it seems better to stress those elements inherited from the past which count for most in the present and the future and to indicate the character of the new forces than to attempt an adequate description of the traditional civilization.

POPULATION

It has been said with some force that estimates of the total population of China have "assumed the importance of an indoor sport unencumbered by any definitely established rules." One reasonable estimate of China's population, the post office census of 1926, returned a total of more than 485,000,000 for China proper (including Manchuria). Allowing 11,000,000 for Mongolia, Tibet and Sinkiang, a round total of 496,000,000 is reached. At the other end of the scale, the census of the board of the interior in 1910, shortly before the fall of the Manchus, put the figure for China proper with Manchuria as low as between 323,000,000 and 343,000,000. The total population of China may reasonably be put at about 400,000,000, but authorities differ vigorously as to whether it is less than or more than this figure. According to official estimates, the population in 1950 was 475,000,000. Particularly important is the extraordinarily uneven distribution and almost unparalleled density in certain areas. The bulk of the population of China is contained in the following regions:

1. The central portion of the north China plain around the convergence of the provinces of Hopei, Shantung and Honan and a section of the valley of the tributary Wei river.
2. The triangular tract of the Yangtze delta with its apex at Nanking.
3. A relatively narrow coastal belt extending southward from the Yangtze mouth through Chekiang, Fukien and Kwangtung to the Si Kiang or Canton delta, where it widens considerably.
4. The central (Hupeh) basin with the Wuhan cities (Hankow, Hanyang, Wuchang) as its node and extending up the radial valleys converging on it (Han, Siang, Kan, etc.).
5. The Red basin of Szechwan, isolated far in the west beyond the Yangtze gorges.

The northern belt of maximum population is essentially one of peasant farmers, depending upon the land; large cities are rare and industries relatively few. In the Yangtze delta, the coastal zone and the Canton delta agriculture greatly predominates, but in addition there are old and new industries and active river and maritime commerce. The merchant classes form a

bigger element, and great cities are numerous. That these great regions as a whole, but particularly the northern plains, are supersaturated with human beings relative to the present means of subsistence there can be no question. It is attested by the appalling frequency of famines in the north (about one in every three years) and to a lesser extent in the lower Yangtze, and by a very low standard of comfort which allows of no margin.

Outside these regions, population is dense only in isolated valleys or small basins. In the provinces of the loess plateau (Shensi and Shansi) the density is moderate and the population fairly evenly distributed. The same may be said of the south China plateau as a whole. In both, well-peopled valleys contrast with sparsely occupied highlands. The southwestern provinces (Kweichow, Yünnan and Kwangsi), Kansu, the provinces of Inner Mongolia in the northwest and the Manchurian provinces in the northeast all have distinctly low densities. The possibility of lessening the pressure of population, if that could be accomplished, would depend upon developing industries and new agricultural techniques, internal migration and gradual changes in reproduction patterns.

Migration.—The Chinese have been throughout their history a colonizing people, but the mobility of movement from congested and overpeopled regions to sparsely occupied areas was constantly held in check by the great reluctance, for reasons connected with their social philosophy (*see* below), to leave their ancestral homes. This is least true of southeast China. There has long been an increasing stream of Chinese emigrants from Fukien and Kwangtung, with their densely peopled coasts, to the rich peninsulas and islands to the south, where they helped to develop the far eastern tropics. In Malaya Chinese form more than one-third of the total population. In the Philippines, in Java and many other parts of Indonesia, in Thailand (Siam), in Indochina and in Burma their vigour, frugality and tenacity make them a prosperous and progressive element. These same qualities often constitute a menace to the economic prospects of the less energetic native peoples. These important and thriving Chinese communities retain close contact with their ancestral provinces, the latter receiving large remittances from them and being influenced by them in many ways.

The peoples of the congested districts of the north in Shantung, Hopei and Honan were until relatively recently somewhat less adventurous. The rich grasslands of Manchuria beyond the Great Wall only became available for agricultural settlement under the Manchu dynasty, and economic development was very slow until after the Russo-Japanese War of 1904–05. With the rapid development of railways and new industries, Manchuria became a very attractive field. North China, on the other hand, was devastated by famines and the ravages of civil war. The almost intolerable conditions of life in many districts so weakened old prejudices that a tremendous mass movement toward Manchuria set in. It was no longer a mainly seasonal migration of males, but a wholesale exodus of entire families. The increase of population in Manchuria in the four years 1923–27 was estimated at 2,000,000 and the exodus from north China during the summer of 1928 at 40,000 a week. During the period of Japanese control of Manchuria, 1931–45, migration was slow but steady. After the area came under control of the Communist regime, it was developed as an agricultural-industrial base, and migration, particularly of skilled workers and technicians, was encouraged. To this field of colonization in the north must be added the adjacent districts of Inner Mongolia on the Chinese side of the Gobi desert, with very considerable pastoral possibilities which the Peking-Kalgan-Suiyuan railway made accessible. However, this is a marginal region in which the small and fluctuating rainfall makes settlement and livelihood precarious. In spite of climatic limitations, northern China has thus had a "land of promise" along its whole northern border, but except for some sections of Manchuria this nearly reached the saturation point. The tendency to overpopulation, which is the root cause of the grinding mass poverty of so many districts and which underlies so many of China's problems, results essentially from social causes. The Communist regime attempted by a drastic reorganization of the society and economy to solve this fundamental problem, but with what success it is difficult to predict.

CHINESE SOCIETY

The Family System.—In preceding paragraphs the diversity of China has been emphasized. But more significant than the diversity is the cultural unity which held Chinese civilization intact for more than four millenniums. The basis of this fundamental unity was the family system which dominated Chinese society and permeated almost every aspect of economic and political life. The sanctity of the family found expression in what the western world would regard as an excessive reverence for ancestors. It is the cornerstone of the Confucian teaching, which gives first place to the virtue of filial piety and discourages children from going far away from their aging parents. It is the *raison d'être* of much of the ceremonial prescribed by the etiquette to which Confucius and all his interpreters attached immense importance.

Associated with the family have been the elaborate and expensive rites connected with marriage and death, the maintenance of ancestral halls, the family reunions at fixed seasons, the erection of memorial arches to virtuous widows who refused to remarry, and countless other symbolic acts.

In comparison with the family, the individual has counted for little. To it he has owed implicit loyalty. Marriage, for example, has been a contract between two families arranged without reference to the individuals concerned, usually when they were both young children and often without their having seen each other. The family in its extended form as a clan has served the function of insurance and benevolent societies in Europe, and the provision of clan funds for education enabled many a promising boy to qualify for public office.

The association of families in a community provided a system of local government enabling village and district life to maintain an effective organization even during periods of political anarchy. The village attempted to avoid relations with officials of the central government or to reduce them to a minimum. The group of elders, selected from the wisest and most experienced heads of families, combined many of the duties of an English parish council, board of guardians and bench of justices of the peace, and dealt with the higher state officials. Their meeting place, the village temple, became the centre of social life. So, too, the offices connected with the affairs of the village were held in succession by the principal family heads.

Thus the basis of the system of government became patriarchal. The old China was in a sense a social democracy of myriad families whose relations were determined by an elaborate social code requiring obedience to an emperor who was himself regarded as at once the supreme patriarch and the "son of heaven," with power equalled only by his responsibility. If by his actions he incurred the wrath of the Spiritual Father on the immense family which he represented, he had plainly "exhausted the mandate of heaven" and revolt against him was justified.

The bureaucracy through which he worked was immensely complex and intended to counterweigh local and provincial interests, but the same patriarchal conception was seen in the functions of the head of the *hsien*, the one state official with whom the masses in the countryside and smaller towns came into contact. The *hsien* magistrate was entrusted with a great variety of duties and under the old regime essentially represented government to the people. In the city of Peking the Temple of Confucius, with a large hall preserving the ancestral tablet of the sage enshrined in an alcove, adjoined the Hall of Classics, where the emperor came on state occasions and whose courtyard contained 300 stone steles on which the complete texts of the "nine classics" were inscribed. The juxtaposition of two of the most famous buildings in the country symbolized the intimate relationship between the massive social fabric based upon the family and the traditional scholarship of China. This scholarship, of high antiquity and unique continuity, furnished alike the sanction of the social system, its support and its cultural background. Ethical teaching about social obligations, summarized in the five relationships

(sovereign and subject, parent and child, husband and wife, elder brother and younger brother, friend and friend), lay at the heart of a moral code already hallowed by antiquity when Confucius gave it coherence.

It was largely through schools provided by the family or clan for its own members that the rudiments of its teaching were given to the rising generation. By a graded system of public examinations, proficiency in this learning in its more advanced aspects was tested as the qualification for public office, on the principle that only those who understood the foundations on which society rested were fit to be entrusted with affairs of state. Thus the scholars were the governing class and the social aristocracy during long periods of the past 2,000 years. They enjoyed immense prestige and ranked first in the four recognized groups (scholars, farmers, artisans, traders). They could not transmit their offices to their children, but in practice retired officials had exceptional means for giving their children the necessary education, so that many families had at once wealth, usually invested in country estates, and literary traditions, and constituted the literati or gentry, the notables of the countryside and small towns. Yet they were never a caste apart, and their ranks were open to any peasant's or craftsman's son who could qualify. The recognition of an aristocracy of learning, the recruitment of the civil service by competitive public examinations (from the time of the Han dynasty) and the absence of caste distinctions were three outstanding features of the old Chinese civilization complementary to the patriarchal system and adapting it to a complex state organization.

To the family system China largely owes the remarkable social stability which has enabled it to survive the many shocks which the political fabric has received and to outlive many far more highly organized communities. Many of the most attractive aspects and some of the most fundamental virtues of the Chinese character are bound up with it.

Yet the cult of the family is an important cause of the intense pressure of population in the land. Among the peasantry there was need for sons to work the fields, although economic pressure also acted to limit family size. Among the gentry which had its economic basis in farm lands rented to tenants, families tended to be large and to consist of several generations of adults and children living together. Concubinage was not uncommon in this class. The social premium on male progeny (to ensure the perpetuation of the family line) led to early marriage, concubinage and a high birth rate, and the first result of this chronic tendency to overpopulation, in a country so largely composed of peasant proprietors, where no law of primogeniture existed, was naturally the excessive subdivision of land. The abnormally low standard of living and the absence of any economic reserve explain the existence of a "submerged tenth" of desperate men, ready to adopt brigandage. Hence the contrast between the singularly peaceful and law-abiding character of the Chinese as a whole and the frequent disorder and terrorism in country districts when authority is relaxed. Hence too, the ease with which armies can be raised in a country essentially unwarlike and the extreme difficulty of disbanding them once they have come into existence. Excessive emphasis on the family also proved a potent cause of China's political weakness, since family interests were constantly preferred to those of the state. Nepotism, in fact, has been described as a religious duty in China, an obligation to use public office for the benefit of the family group as the supreme object of loyalty. Many individuals attained to a larger vision, but usually there was a marked contrast between the admirable honesty and trustworthiness of the Chinese in their individual and trade relations and the corruption which tended to characterize their public life and to ruin large-scale undertakings lying outside the traditional group organizations. The state, as such, traditionally meant very little to the vast majority of the Chinese people. China has been a civilization rather than a national entity in the European sense.

Industry's Influence.—Even before the Communist regime began its effort to reduce the control of the family in favour of that of the state, many influences were at work in modern China to reduce the importance of the family and to disintegrate the traditional structure of Chinese society. One of these was modern industry. The most important effects of industrialization are at present localized in the cities of the Yangtze and Canton deltas, the central basin, at nodal points along the main railways, at several of the seaports and in Manchuria. The Communist regime exerted great effort in the attempt to industrialize China. In these centres there is a large and increasing class of industrial workers of a type quite new to China. They are losing touch with the corporate life of the countryside and are increasingly detached from the traditional social heritage. A large proportion of them are women, and the entrance of women into large-scale factory industry implies at once their growing economic independence and the breakdown of the clan system.

Nor is that all. Industry and commerce in China were formerly almost entirely controlled by the guild system. The guilds are group organizations of various types, but like the family organization all make the well-being of the individual dependent on his obedience to the code governing the interests of his craft or trade or, in the case of provincial and city guilds, of his locality. Large-scale industries of western type employing the new class of artisans are for the most part outside the guild system, and the workers, often living under conditions similar to those of the factory towns of England in the early days of the Industrial Revolution, proved to be open to the appeal of new influences such as the western trade-union movement and communism.

That the old capacity for combination was capable of taking new forms was shown by the many examples in modern times of relatively successful strikes and boycotts. Under the Communist regime, however, all labour was organized into unions under control of the party. The ever-widening use of machine-made goods, manufactured abroad or in China's new factories, seriously disrupted the peasant economy, which depended upon subsidiary handicraft industries to supplement farm income. The destruction of cottage industry and the increased commercialization of agriculture to the disadvantage of the small farmer acted, in combination with many other factors, to pauperize the peasantry. This general tendency likewise disrupted the traditional social order.

Modern Educational System and Linguistic Reforms.—Of the new cultural forces which tended to disrupt the traditional family and other phases of the hereditary culture the most outstanding, before the advent of the Communist regime, were the modern educational system, the student movement and the penetration of new ideas from Europe, the U.S. and modernized Japan. The sudden abolition of the old classical system of examinations in the last years of the Manchu dynasty marked a dramatic break more fundamental in effect than the abolition of the imperial office seven years later. In spite of many difficulties, a system of schools gradually emerged in which, while western subjects and methods predominated, traditional language and literature still found a place. The most revolutionary of the social influences of the new education were: (1) The granting of educational facilities to women and the introduction of coeducation in primary schools. In conjunction with the economic forces already noticed, this produced a remarkable change in the status of women and the relations between the sexes. Many young persons now arrange their own marriages without consultation with their elders. (2) Western science, very imperfectly organized in China, but implying a mental discipline of a kind quite foreign to the old literary training. (3) The ideal of mass education. In respect for learning no country excelled China, but in the past it was always associated with a relatively small group of scholars. Both the Nationalist and the Communist regimes worked hard to extend the public educational system. Because of the huge population, the country's poverty and the decades of war and political disorder, the creation of a modern national educational system has been a slow process. The mass education movement was aimed to overcome China's widespread illiteracy. There were few more promising features in modern China than the almost passionate enthusiasm with which the students and teachers of secondary schools and colleges organized

the popular educational movement, devoting evenings and parts of vacations to the conduct of free schools for poor children and adults. The mass education movement, inaugurated by a returned student from the United States, greatly aided the progress toward literacy. Mass education was pushed with energy by the Communist regime. In the linguistic field the popular vernacular (*Pai-hua*) of the Mandarin dialect became the accepted medium for new literature, in place of the old classical and "dead" language. The change was comparable in character and importance to the adoption of the vernacular as the medium of literary expression in place of Latin in Chaucer's England and Dante's Italy. Further, out of the vast number of Chinese characters, 1,000 (or even 600) of the most essential were selected for use in the people's schools—hence often called "foundation character schools"—and were used exclusively in the writing of appropriate popular books. A standard form of the Mandarin vernacular (*Kuo-yü*) was taught in the schools throughout the country, a procedure which tended toward uniformity in the spoken tongue and toward national linguistic unity.

The "New Tide."—These important linguistic reforms, especially the development of the new national language (*Pai-hua*), were to a large extent the outcome of the remarkable movement known as the "new tide" or Chinese renaissance that flourished during several decades after 1915. This movement, associated with the new intelligentsia in the chief centres of thought, such as the National university at Peking, owed its origin to returned Chinese graduates of foreign universities (especially Paris and certain U.S. universities) and in particular, on its literary side, to Hu Shih often called the "father of the Chinese renaissance." This renaissance was an intellectual ferment similar in many ways to that which characterized the revival of learning in Europe. On its literary and linguistic side it was essentially constructive while critical in many other respects. Especially notable was its vigorous and unsparing attack on the inferior status of women, child betrothals and costly expenditure on funeral rites. On its more speculative side it was concerned with what its exponents described as a "revaluation" of Chinese thought and philosophy in the light of western science and knowledge. In the sphere of religion it was for the most part sceptical and rationalistic and helped to give birth to a widespread but transient anti-Christian movement in the ranks of "Young China." At the same time the movement in many of its aspects included some of the most distinguished of the leaders of Chinese Christianity.

Religion.—The disintegrating effects of the new influences inevitably invaded the religious sphere, but in many respects the break with the past in this field was less complete and revolutionary than in some other aspects of life; however, there was, even before the Communist regime, some change, and traditional religion and religious observances were greatly weakened. Of the three historic religions of China (*see* under *History*), Taoism in its later phases has been little more than a congeries of superstitions which must gradually lose their vitality. The same may be said of the cruder side of popular Buddhism, especially in its northern form (Lamaism), but in its more philosophical aspects Buddhism has a definite adaptability and is by no means a negligible factor. Confucianism, although it has a religious aspect, denotes a social code and an attitude toward life rather than a religion. Although obviously weakened by the changed conditions it retains great vitality; it forms the mental background and in part orients the lives of many educated Chinese who hold no definite religious beliefs. The average attitude of the majority of educated Chinese may probably be described as an agnosticism coloured and softened by Confucian and Buddhist tendencies.

The influence of Christianity proved considerably greater than the relatively very small number of its adherents would indicate, and the Christian community played a part in the public life of China out of all proportion to its numbers. Under the Communist regime foreign Christian missionary enterprises were nationalized and almost all missionaries compelled to leave. Yet an indigenous Christian church, subservient to the regime, was not discouraged. While the Communist revolution was corrosive of all the older religions in China, "Marxism and the thought of Mao Tse-tung" was elevated to a national cult.

Thus in modern China the mature old civilization has been changing under pressure from within and without. Yet many-sided as is the revolution through which the country is passing, prolonged as must be the social turmoil and difficult the integration, there are many elements in the heritage of the past still vital and making for stability. (L. H. D. B.; K. S. L.; C. M. W.)

ECONOMIC AND POLITICAL CONDITIONS

DEFENSE

Historical.—Up to the date of the reforms of 1905–06 the Chinese constitution provided for two sorts of military organization, the Manchu army and the Chinese armies in the provinces. When the dynasty was originally established in 1644, the victorious troops, composed mostly of Manchus but including also Chinese and Mongols, remained in Peking as a hereditary national army. Every adult male was entitled by birth to be enrolled as a soldier under one of the eight banners and, after enrolment, to draw an allowance of tribute rice, whether or not employed on active service. Some were sent to garrison such places as Canton, Foochow, Hangchow, etc., but the bulk of them, both in Peking and in these garrisons, lost all military value. The other military organization, the provincial forces, was styled the army of the green standard and resembled a local constabulary rather than an army. Its soldiers were poorly paid, virtually untrained and badly armed. Their ineffectiveness as a military force was fully exposed by the outbreak of large-scale rebellions in the 1850s and 1860s. Such rebellions as the T'ai P'ing, the Nien and the northwest Moslem spread over many provinces. Their eventual suppression was accomplished not by the decayed regular provincial forces or the Manchu army but by the newly organized Hunan and Anhwei "braves" or irregulars. It was also the leaders of the new forces who made a few beginnings at building modern arsenals and in training troops in modern ways. After the war with Japan in 1894–95, some of the corps of braves were quartered near Peking and Tientsin and became spoken of generally as the army of the north. By 1900 this was the only real fighting force of China. After the Boxer rising of 1900 an imperial decree ordered the reorganization of the military forces of the empire and something was accomplished on provincial lines, especially in Hopei, but little was done toward establishing an army on European lines until after the Russo-Japanese War of 1904–05, when various military schools and training organizations were established (or provided for on paper).

By 1910 some progress had been made toward evolving an efficient body of officers. An army board was organized and progress made with a general staff. Service, mostly voluntary, was for three years with the colours, three in the reserve and four in the territorial army. Reservists were called up annually for training and territorials once in two years. The Japanese system of training was followed.

China, although a belligerent on the side of the Allied powers, took no effective part in the victory which they achieved over the Central Powers in World War I. The country was in the throes of internecine strife. In the spring of 1919 the governments of Great Britain, Spain, Portugal, the United States, Russia, Brazil, France and Japan agreed "effectively to restrain their subjects and citizens from exporting to or importing into China arms and munitions of war and material destined exclusively for their manufacture, until the establishment of a government whose authority is recognized through the whole country." The governments of the Netherlands, Denmark, Belgium and Italy adhered to the agreement and the diplomatic body appealed to the Chinese government to prohibit imports. No effective action was taken, and the Soviet government added its activities to those of the nationals of some of the signatory powers in carrying on this traffic, with deplorable results. The import of war material, of which a large surplus remained for disposal in belligerent countries at the time of the Armistice, was largely supplemented from the resources of numerous arsenals and factories

in Chinese territory, such as those at Mukden, Paoting, Tehchow, Chinan, Tai-yuan, Kai-fêng, Kunghsien, Sian, Hanyang, Nanking, Shanghai, Changsha, Chêngfu, Foochow, Canton, Swatow, Kiungchow (Ch'iung-shan), Kunming (Yünnanfu) and Kalgan.

Army.—Any attempt to describe the army in modern China in terms of accurate statistics is futile. For years after the revolution of 1911 various war lords had larger or smaller units in various stages of equipment and poor training and discipline. Most of these armies were in theory part of the national forces, but in practice they were not co-ordinated under any general staff or supreme command. Their total enrolment ran into the millions, but few if any were effective fighters. They were largely a refuge for the riffraff and the unemployed, a way of taking care of some of the many millions who were thrown out of their normal occupations by civil strife and natural disasters in a land in which the margin of subsistence was always slender. The transition from bandit to soldier and from soldier to bandit was usually easy and was very frequent. Equipment was inferior and discipline, training and leadership worse. Battles between the war lords were aptly characterized as "much noise, little fighting, less damage." Loss of life, except through disease and to noncombatants through starvation occasioned by the destruction of the means of subsistence, was slight. The coming of the Nationalist government in 1927 brought some improvement. The prolonged struggle against the Communists and preparation against the Japanese menace forced progress. Such leaders as Chiang Kai-shek, Li Tsung-jen and Pai Chung-hsi, especially the first, brought various advances. Schools for officers turned out a better leadership. Here and there arsenals began to supply native-made equipment, mostly small arms and trench mortars. German officers supervised the training of the army.

At the outbreak of the war with Japan in 1937 the Chinese army was well past the 1,000,000 and possibly the 2,000,000 mark. But in officers' training and mechanized equipment it was still far behind its opponent. Many of the best troops were sacrificed in the early stages of the war. New armies were recruited in "Free China," to the west of the Japanese lines. Some troops were drilled and equipped in India, mainly by Americans. The Communists who fought with the Nationalists against the Japanese under the united front policy used guerrilla tactics and expanded their forces rapidly behind enemy lines. Before the Japanese invasion of China in 1937 and after the successive campaigns waged by the Nationalist army against the Communists, the Communist army that retreated to Shensi amounted to fewer than 30,000 men. By 1940 it had grown to 500,000. After the conclusion of World War II, the Nationalist army was estimated to be more than 3,000,000 and the Communist army was estimated to be almost 1,000,000 with a militia of more than 2.000,000. In 1949 the mainland of China was overrun by the Communist army. Only one-tenth of the Nationalist army retreated to Formosa (Taiwan); most of the rest surrendered. The Chinese army on the mainland in 1953 was composed of the following: four field armies of 22 army corps divided into 70 armies, including special service corps, estimated at more than 2,000,000; the military district armies estimated at 2,000,000; and a militia of more than 12,000,000. There were also the people's security forces of 250,000, whose duties were the suppression of local disturbances.

Air Forces.—Up to the early 1950s all aeroplanes had been of foreign make. When the Communists took over the Chinese mainland, they captured 183 aeroplanes from the Nationalists. Before the Korean war, there was only one pilot-training academy in the northeast. Together with aircraft purchased from the Soviet Union, there were fewer than 600 planes, including about 30 jets. The objective was to match the air power of Formosa. After the Korean war, pilot-training academies were established in the various military districts and the number of planes was increased to more than 1,200 in 1952, including a large number of jets. Two paratroop headquarters were also established in Peking and the Wuhan area. The total personnel of the air forces on the mainland reached an unprecedented 200,000.

Foreign Troops.—Though not strictly germane to the subject of Chinese armies, it is important in this connection to consider the presence of foreign troops in various parts of China. In the north, Peking and Tientsin, they had the right, by the protocol of 1901, to put the legation quarter in a state of defense and to occupy selected points between Peking and the sea. Japan had troops in the South Manchuria railway zone under a treaty of Dec. 1905 with the Chinese government. Foreign garrisons in the north, distributed between Peking, Tientsin, Tangku, Tongshan, Chinwangtao and Shanhaikwan, were strongly reinforced in 1927, during the conflict between north and south. The total number at the end of 1927 was 11,880, compared with 4,740 in 1926. The nationalities, in order of numbers, were U.S., French, British, Japanese and Italian. The Shanghai defense force, amounting to a mixed division with armoured cars and attached troops, was in 1927–28 gradually reduced in strength to about a brigade. The Japanese invasion which began in 1931 in Manchuria and by stages, chiefly following July 1937, extended to the rest of China, strikingly altered this picture. After 1931 the Japanese army dominated Manchuria. Forces of possibly as many as 1,000,000 or more men were poised on the northern borders, ready to resist a Soviet advance or to take advantage of Soviet weakness to acquire eastern Siberia or Outer Mongolia. After 1937 Japanese forces were also distributed widely through occupied China south of the Great Wall. They may have totalled another 1,000,000 or more. Foreign troops of other nationalities were withdrawn before Dec. 1941. The Japanese domination ended with the conclusion of World War II. On the Chinese mainland in 1952 Soviet troops totalling about 60,000 men were disposed in the Port Arthur and Dairen area as agreed by the People's Republic of China and the Soviet Union on Feb. 14, 1950. Some Russian troops were also reported to be disposed along the Chinese Changchun railway in the northeast, in Peking, Tientsin and Tsingtao, in north China and in Ili, Urumchi and other places in Sinkiang. (G. G. A.; K. S. L.; C.-L. C.)

Navy.—The beginning of a navy in China dates from about 1867, approximately the same period as that which saw the introduction of the telegraph into the country. A shipyard at Foochow turned out a few small composite gunboats, and a training ship was bought and placed under the command of a British officer. Several armoured cruisers were ordered from England, while naval bases were fortified at Port Arthur and Wei-hai-wei.

Forts were also built and guns mounted at Foochow, Shanghai, Canton and other points which appeared vulnerable from the sea. Money for those purposes was forthcoming from the customs duties on foreign trade.

The Chinese fleet had not, however, developed into a formidable force when, in 1884, France had occasion to take reprisals against China for attacks by irregular troops in Tongking. A wretched collection of craft, the chief of which was the "Yang-Woo," a composite cruiser, was practically wiped out by a French squadron in seven minutes in the river Min, where it had taken cover, near Foochow.

In 1894, when China found itself at war with Japan, the former country had an appreciable fleet, in fact one which on paper was stronger than its adversary's, but because of the disorganized state of administration only one out of the four squadrons into which it was organized took part in the hostilities. This squadron consisted of two small battleships, the "Chen Yuen" and "Ting Yuen," built in Germany, five other small armoured vessels and six sloops. It had attained a good standard of discipline and efficiency under Capt. W. M. Lang of the British navy, but after his departure, and by the time war broke out, the ships had deteriorated and the personnel had relapsed into their normal state of inefficiency. The squadron was defeated by the Japanese fleet at the battle of Yalu.

In 1909 an effort was made to re-establish a fleet, and a naval commission under Tsai Hsün, a brother of the emperor Kuang Hsü, was sent to Europe to obtain the necessary information and advice. Various societies had already started in several provinces to collect funds for naval purposes.

At this time the fleet consisted of four armoured cruisers, some modern gunboats built in Japan, a few miscellaneous vessels and some old torpedo boats, but the efforts of China to create and

maintain a navy were never crowned with success, chiefly because of the corruption of the government and the irresponsibility of the officers. No marked improvement was made by the Nationalist government. In their invasion of China the Japanese had unchallenged control of the sea.

In 1952 the Peking government had three fleets with bases at Dairen, Tsingtao and Canton. There were altogether about 350 ships totalling more than 90,000 tons; personnel totalled about 30,000. Naval academies were established in Antung and Tsingtao. There was in addition a marine corps of 50,000 men.

(E. A.; K. S. L.; C.-L C.)

AGRICULTURE

Characteristics of Chinese Agriculture.—Chinese agriculture is distinguished primarily by its intensity. This is made possible only by the unremitting labour which the struggle for existence demands and the traditional skill born of 40 centuries of transmitted experience. The maintenance of soil fertility under constant intensive cultivation for such an immense period is in part secured by replenishment with canal mud, as in the Yangtze delta, or by the silt deposited by river floods (otherwise disastrous), but in the main by the use of night soil and every other possible kind of manure, applied to the land in primitive but effective fashion. Soil is composted with organic matter and ashes and then dried and pulverized to form a plant food. Deforestation took place not simply to make room for more arable land but as the result of a constant quest for green manure. In hilly districts, such as the loess plateau and the Red basin, the fields on the valley slopes are terraced and rimmed so that the runoff may be retained until the suspended matter has settled. Again, in crop rotations, legumes have long been grown to fertilize the soil. A system was evolved whereby two, three or even four crops are grown in the same ground space each year, while as many as three crops, each in a different stage of development, grow simultaneously in one field. In few countries has the practice of multiple cropping been so perfected. The great traditional skill of the Chinese has raised their agriculture to the level of an art; they show, moreover, remarkable ingenuity in adapting means to ends, as in the many uses to which they put bamboo or millet. Their implements, moreover, are effective, if primitive. On the other hand, the typical Chinese farmer traditionally knows nothing of science as applied to proper seed selection, experiments in better crop rotation or animal breeding and the fighting of plant and animal pests. His methods are essentially conservative and traditional, and little use is made of chemical fertilizers. Notwithstanding great industry at certain seasons, there is much idle time in winter, especially in the north, which the development of small rural industries on a co-operative basis would employ to great advantage in the farming community. There is little combination for the purchase of seeds or implements or for the marketing of produce. Important experiments to remedy these defects have been begun. Some have been undertaken by local governments and some by the ministry of agriculture. Others have been associated with agricultural colleges or departments. By the early 1950s these colleges had graduated more than 6,000 students, serving in agricultural and related fields. More effective utilization of agricultural resources in terms of greater output per hectare and greater output per man-hour, and improvement in marketing and rural finance, would improve the general welfare of the Chinese farmers.

Agricultural Regions.—The salient characteristics of the major agricultural regions can be summarized most easily in relation to the scheme of the natural divisions of China, except that the essential features of crop production and farming methods in the Red basin closely resemble those of the lower Yangtze valley.

1. The Tsinlingshan mountain complex delimits the agricultural "province" of north China. There severe winters and the short and rather uncertain rainy season preclude winter crops. It lies beyond the limit of the cultivation of wet rice, which as a staple crop is replaced by millets and wheat. Rice, it is true, is a subordinate crop in favoured districts of north China; it is known, however, as small rice and is really a glutinous millet. Most people live on wheat, kaoliang and millet, while meat and potatoes play a part in the diet. Soybeans, too, are important. Barley and maize are extensively grown.

The soils of the loess lands are of unusual fertility because of their fine texture, their porous and friable nature and the presence in them of soluble mineral matter for plant nourishment. On the other hand, the region is the driest in China, and, except in the basins, is incapable of manual irrigation. Arable cultivation is therefore often precarious, and there is greater reliance on sheep and cattle.

In the extreme northwest pastoral products and some associated manufactures of coarse woollens and cloths are important products. There occurs the greatest concentration of sheep, raised primarily for wool. Cattle, elsewhere in China almost exclusively draught animals, are raised in the northwest for dairy and leather products; there are distinct prospects for leather and woollen manufactures in parts of the loess belt. In the loess basins such as Tai-yuan and Tatung, where well irrigation and terrace cultivation reduce the risk of crop failure, the hardier cereals are often accompanied by fruit culture (apples, pears, plums, walnuts, apricots, strawberries and the jujube) and also by cotton. (For agriculture in the northwest *see* KAN-SU and SHENSI.)

The plain of north China east of the Taihang Shan, which forms the edge of the loess plateau, has a slightly higher rainfall, but risk of flood is much higher and the great problem is the control of the Hwang-ho, Hwai and northern rivers. Main reliance is on wheat, barley, millet, buckwheat and maize, together with vegetable crops, especially rape, beans and peas. Rice is grown in southern Shantung and northern Kiangsu (*i.e.*, on the borders of the Yangtze "province") and cotton and hemp in Shantung and Hopei, but there is little room for any but subsistence crops. In Shantung there are three crops in two years, the usual rotation being wheat in spring, beans in autumn and finally millet, which is gathered in the following September. As an alternative, wheat or barley in winter and spring may be followed by large or small millet, sweet potatoes, soybeans or peanuts in summer. Animals are less important than in the northwest, but in the parts of Hopei adjacent to Mongolia there is the largest concentration of horses, mules and draught animals to be found in China proper.

2. The Yangtze "province," with rich alluvial basins, relatively high, well-distributed rainfall, seasonal rhythm of moist, subtropical summers and mild winters and magnificent natural waterways, is one of the most favoured agricultural regions in the world and the premier granary of China, supporting nearly half its total population. The combination of summer "wet" crops and winter "dry" (temperate) crops gives it a marvellous range of production, and most of the staple products of China, whether subsistence or commercial crops, find there their optimum conditions. It is easily first in the production of rice, the chief food of all central and south China. If Chekiang is included, it produces more than 68% of the total output of silk, the oldest and most famous of Chinese commercial products, and about 50% of that of cotton, one of the chief factors in the new industrial development. It is also the largest centre of tea production. In some districts, as in parts of the Yangtze delta and the central basin, the rotation is determined by the needs of a special crop. In the normal agricultural year barley, wheat, beans and peas are sown early in winter and harvested in May (wheat in June), followed by sesame, sown after the wheat harvest and ripe early in September, while rice may be either an early crop, planted early in April and ready for harvesting 90 days later, or a late crop planted in early June and harvested after 110 days. If rice is grown for commercial purposes it receives special attention and the fields are ploughed and prepared in early winter. Cotton lands also require special preparation. While this is the regime of the lowland basins, the uplands of central China, especially between the Tungting and Poyang lakes, are associated with the cultivation of the tea plant and the tallow tree.

3. The southeast China highlands are not unlike those of central China, and the ranges of Fukien form the second great tea

district, but the valleys and basins, with more abundant rainfall and warm winters, can grow subtropical crops all the year round. In the most favoured regions such as the Canton delta there are two or even three rice crops a year, and the sugar cane finds its optimum conditions. Largely confined to this section of China are the pineapple, spice-yielding plants such as cinnamon and cassia, ginger and aniseed. The southern coast of Kwangtung and the island of Hainan, with an exceptionally high rainfall and uniformly hot conditions, are particularly associated with these tropical cultures. On the other hand, the climate of southeast China is too moist for cotton and for the "dry" cereals which form the winter crops of the Yangtze valley.

4. The southwest is the least developed of all the major regions of China. The high plateaus are scenes of pastoralism and sporadic cereal and poppy cultivation, but the deeply cut and generally narrow valleys, with a damp, unhealthful climate and often still choked with luxuriant jungle vegetation, were not so intensively developed as the more open and accessible basins of the southeast.

Special Products and Associated Manufactures.—Of necessity subsistence crops are of far greater importance in China than commercial products, and this is strikingly shown by the fact that the three greatest food crops—rice, wheat and millets—occupied in 1953 approximately 54% of the cultivated area.

Rice, the staple food in central and south China, took up no less than 28% and had first choice of the land. More than half the land under cultivation in Kiangsu, the richest province, was devoted to it. Yet only four provinces, Hunan, Anhwei, Kwangsi and Kiangsi, normally have a surplus over local needs, and before World War II large imports were made each year from other lands in the far east.

Wheat comes second to rice in importance and replaces it as a food crop in north China. In some northern districts it occupies 40% of the cultivated land, but there must be considerable imports of wheat and flour. The number of wheat eaters steadily increased in northern China, especially in the towns. The annual output, however, could be increased through both extension of the wheat area by "dry" farming in the marginal lands of Manchuria and by an increase of the rate of yield. Flour milling made notable advances, especially in Manchuria.

Millets and kaoliang (sorghum), whose distribution is rather wider than that of wheat, occupied, in 1953, 15% of the cultivated land area of China. They are dominant in Hopei, Shantung and Honan, where they take up approximately one-third of the agricultural surface. Apart from the grain, their by-products are of great value, and in north China the stalks and fibre of the kaoliang replace, for many purposes, bamboo, which reaches its northerly limit in the Hwai river valley.

Tea has long been the chief beverage in China, and since about the 8th century A.D. the cultivation of the tea plant has been a great agricultural industry, localized mainly on the uplands of central China and on the ranges of the maritime provinces but important also in Szechwan. Black, green and brick teas result from different processes of manufacture. The tea plant in China is mainly grown in patches round the homestead, and the methods of both cultivation and preliminary preparation after the picking of the leaves (usually in April, mid-May and August) are traditional and not based on scientific knowledge. Mainly for this reason the chief European markets for black tea were largely lost by China in the later 19th century, when the plantation system, with its associated scientific processes of manufacture, was developed in India and Ceylon. Export of tea from India and Ceylon was 5 times the export from China in 1937 and 20 times in 1947. Brick tea, made by pressing damp leaves into a bricklike mould, found its chief market in Tibet, the U.S.S.R. and interior Asia. Chief ports for tea export have been Hankow (black and brick tea), Kiukiang and Foochow (black tea), Hangchow, Ningpo and Kiukiang (green tea). Experimental stations and investigation bureaus for more scientific cultivation and preparation of tea were opened in the Yangtze valley and at Foochow, and a small beginning was made with the plantation system.

For sericulture, the most far-famed and ancient of its industries, China has many natural advantages, including two or more leafings of the mulberry as compared with one in the Mediterranean countries, and abundant, cheap and traditionally skilled labour in the manipulation of the cocoons and in weaving. In the production of raw silk there are many regional specializations in accordance with the variation of soil and climatic conditions. The silk of the north (Shantung and Manchuria) is chiefly "wild," the product of silkworms fed on oak leaves and manufactured into coarse-textured tussahs and pongees; the Canton delta, where there are as many as six or seven leafings of the mulberry, produces soft Canton silk and Szechwan a special yellow variety. But the most renowned silk region is the lower Yangtze valley, the finest white silk in the world (tsatlee) coming from around the Tai-hu. Exports to European and particularly U.S. markets, although considerable, were surpassed by those of Japan, which added scientific technique to the natural advantages for silk production which it shares with China, where the industry is carried on by peasants on traditional lines. Serious efforts were made by special departments of several colleges and by the International Committee for the Improvement of Sericulture in China to improve the mulberry plantations and to eradicate silkworm diseases, which greatly impair the prosperity of the industry. A more revolutionary change was indicated by the development of large steam filatures and weaving mills at Canton, Shanghai, Soochow, Hangchow, Hankow, Chefoo, Chinkiang and other towns. Even under prevailing conditions, raw silk and cocoons formed more than 9% of the total value of Chinese exports in 1933 and came first in all exports. In contrast, tea, which in 1820 constituted 75% and in 1867, 60% of all Chinese exports, accounted for little more than 5% in 1933.

The most remarkable agricultural development in China during modern times was the rapid growth of the bean industry. Beans long had been grown as an article of food, but the development of the culture on a commercial basis was quite modern and was the result of the realization of the many valuable qualities of the soya variety, which is admirably adapted to north China, and particularly Manchuria.

On the one hand, it has a higher food value than any other seed, which, in conjunction with its cheapness, makes it an effective substitute for milk, meat or the staple grain foods of north China; on the other, its by-products—bean oil as a cooking sauce, as a base in soap manufacture and as a lubricant for various purposes, and bean cake as a fertilizer and cattle food—are of great commercial value.

Beans became one of the major crops in China, next in importance only to rice, wheat and millet. Bean production was one of the principal factors in the rapid economic development of Manchuria. (*See* MANCHURIA.)

Of the purely industrial crops of China, cotton is important. The soil and climatic conditions of many districts of the Yangtze valley and the adjacent parts of the plain of north China approximate those of the cotton belt of the United States. But the industry suffered from many disadvantages: the short staple of the native varieties, primitive methods of seed selection and cultivation, lack of transport and of banking and credit facilities to deal with the movement of crops, and the existence of taxes, which greatly raised its price. Much important work was done by provincial associations and agricultural colleges and departments to improve native varieties and to acclimatize and then distribute seeds of American cottons. It would seem to be established by experiments that late-maturing American cottons will not succeed in the Yangtze delta, with its humid early autumn climate, but can be acclimatized in the central basin and parts of north China where September and October are normally dry, sunny months. An endeavour was made to produce longer-stapled Chinese cottons for the deltaic area.

The great development of cotton mills in China in the first half of the 20th century was the most important aspect of the new industrialism. They were, however, very strictly localized. Of 144 cotton mills in China in 1937, more than 40% were in Shanghai, the great textile centre, and half the remainder were in the Yangtze delta and the central basin. Of the grand total,

96 were Chinese-owned with 2,764,000 spindles and 25,503 looms, and 48 were foreign-owned (mainly Japanese) with 2,503,000 spindles and 37,528 looms.

At the end of World War II, the Japanese-owned textile mills were taken over and operated by the Chinese government. In 1951 production of cotton yarn and cloth on the mainland had exceeded prewar levels. On Formosa there was also a great increase in cotton textiles in 1951. There were 950,000 spindles and 5,392 looms.

The opium poppy has been one of the chief and most widely distributed products of China's fields, and the area devoted to it, reduced to a minimum by the prohibition orders of 1906 and subsequent years, greatly increased during the period of civil war, with its military exactions of illicit revenues. In west China the Nationalist government by forcible measures greatly reduced its growth. During World War II, in some Japanese-controlled areas, a marked increase in opium production as well as in the consumption of opium and its derivatives occurred.

Other important Chinese products, which cannot be separately described, include fibre crops, especially ramie in the Yangtze valley, tobacco (very widely distributed), peanuts, many kinds of vegetable oils, cane sugar and a great variety of medicinal plants and spices.

So great is the need for subsistence crops in China that grazing grounds for sheep and cattle are virtually confined to the dry northwest and to mountain pastures. In the rest of China there is no dairy industry, and cattle are used primarily as draught animals. Moreover, there is a lack of pasture grasses, partly because of the type of rainfall. On the other hand, animals such as swine, goats and poultry, which can subsist on by-products of the farm, are kept in large numbers. Scientific animal breeding has been developed little. Modern China's timber resources are very meagre.

China has an important source of wealth in its sea and river fisheries, which are rich and varied and supplemented by artificial breeding in tanks. The coastal fisheries of Shantung, Chekiang and Kwangtung are especially valuable, and they include some of the world's greatest fishing centres. Fish, both fresh and salted, is a staple article of diet in many districts.

MINERAL WEALTH AND MINING

Coal.—Coal is by far the most important mineral of China, but there is as yet no certainty regarding even the approximate amount of the coal reserves. The revised estimate (1945) of the Chinese geological survey was 265,331,000,000 tons. Through the efforts of survey parties sent out by government agencies, new coal reserves were found in various parts of the country, especially in north China. It indicates a bulk which is probably the greatest in the far east, sufficient to form the fuel basis of a fairly extensive industrial development in China. Of the total amount of the coal reserve estimate, Shansi province alone is responsible for almost one-half.

The annual production of coal in 1938 was 38,900,000 tons. Production in 1951, although only 69% of the peak level of 56,300,000 in 1942, was higher than the prewar average. Coal mines are all intimately related to the existing railway systems, mainly concentrated in north China, and are therefore chiefly located on the small fields scattered around the edges of the north China and south Manchurian plains.

The only really important mine in south China is that of Pingsiang among the hills of the Hunan-Kiangsi border, and this too is linked with the railway system. Much the largest concerns are the Fushun in the northeast and the Kailan in Hopei, whose fields, though small, have each an important strategic position, being in close contact with the railway focuses of south Manchuria and of north China, respectively.

The production of Fushun has been the larger of the two. From these and from other mines in Shantung and along the eastern fringes of the Shansi coal field, coal is exported along the railways and by coasting steamer to the commercial and industrial centres, of which the Yangtze delta is the chief. Chinwangtao, a port close to the Kailan mines, developed a larger coal-shipping trade than any other port east of Suez.

Iron, Oil and Other Minerals.—China's resources of iron are more meagre than those of coal. The 1947 estimate of the Chinese geological survey was 2,554,896,000 tons, while that of the bureau of mineral exploration of the National Resources commission was 5,065,838,000 tons. In 1953 new deposits of iron were located at Penki (Pen-ch'i) in the northeast and at Lungyen in north China. These were not sufficient to form the permanent basis of an iron industry of the magnitude of that of the U.S. On the other hand, the Chinese industry, with a capacity of 1,000,000 tons of pig iron, produced only two-thirds that amount; thus there was room for very considerable expansion.

Mining is most active along the lower Yangtze valley (Tayeh in particular) and in south Manchuria (An-shan in particular), and these two regions are also the chief centres of iron smelting. Before World War II, China was the principal supplier of iron ore to Japan's iron and steel industry, the major utilizable iron resources being virtually controlled by Japan. The 1936 ore production was 3,360,000 tons. Wartime disruption brought operation to extremely low levels, only 150,000 tons being produced in 1947. Rapid recovery began to take place after 1950, but in 1952 the production was still below the prewar level.

Oil reserves in China have always been greatly underestimated. Extensive surveys were undertaken but they had not been completed by 1953. The known oil reserves in China have been estimated at 778,855,000 tons, including 520,000,000 tons of oil shale. Small deposits of lead, zinc, silver, copper and tin have long been worked in many parts of the country. The most important copper and tin mines all lie in Yünnan and adjacent southwest Szechwan. Of some rare metals, particularly antimony and tungsten, China became the leading producer of the world.

In conclusion it may be said that China, though not richly endowed with all kinds of minerals, has many varieties of them which are necessary for its future economic development. These minerals had not been fully exploited by the early 1950s. With improved transport facilities and more favourable economic conditions, China might develop great mining activities.

MANUFACTURING

From what has been said in the preceding sections it must be clear that industrial development in the modern occidental sense of that term was still in its infancy in the early 1950s. In the older, premachine age, manufacturing was in the handicraft stage and was carried on in countless small units organized by guilds. Handicrafts persisted as the prevailing method of manufacture. Some were weakened by competition with foreign machine-made goods or, in cottons, by modern factories in China. Factory development was mainly, although not exclusively, in the manufacture of cotton textiles. There also were established silk filatures, flour mills, match factories and some steel works. Industrial development was retarded by civil strife and foreign wars, since both domestic and foreign capital were reluctant to invest extensively in equipment which might be destroyed by contending armies.

Before the war with Japan began in 1937, industry had been developed mainly in the lower reaches of the Yangtze valley. After 1937 industrial development made rapid progress in the interior provinces. After the government laid special emphasis on the heavy and the basic chemical industries, the growth of the heavy industries overtook that of the light industries.

COMMERCE

Currency and Banking.—At the dawn of the 20th century China's only domestic coinage was copper, in coins known by the foreigners as "cash." This could be employed only for relatively small transactions. Larger transactions were in silver bullion. The unit was the tael (Chinese liang), which varied in weight from locality to locality and agency to agency. Silver dollars of foreign minting, largely Spanish and Mexican, had been imported and were in increasing circulation. Domestic banks were chiefly for the purpose of facilitating internal commerce and exchange, although some received deposits and made loans. In the larger

ports there were foreign banks, chiefly British.

In the course of the 20th century the "cash" largely disappeared. Silver coins corresponding to the dollar and called yuan were minted, and a subsidiary coinage, theoretically decimal, appeared. The yuan or dollar was legally substituted for the tael. There was much use of paper money, but silver remained the basis of the currency. In the 1930s the country was drained of much of its silver by purchase from abroad. Remaining stocks of silver were nationalized in Nov. 1935. From that time only the paper money issued by the government banks was allowed to circulate. In 1953 the official currency was the jenminpi or People's bank note on the mainland; on Taiwan it was the hsintaipi or new Taiwan dollar. There was an extensive development of banks, both government and private, of occidental types. The capital of these modern banks, however, was not made available to industries, except in the form of short-term loans. Investment banking, necessary to the industrialization of the country, was one line of activity which had not yet developed.

Foreign Trade.—The origin and characteristics of the system by which the foreign trade of China was organized from the middle of the 19th century down to relatively recent times are explained in the section on *History*. Some changes of great importance are indicated below. Tables I–IV, showing the total foreign trade for 1933 and 1947 according to the returns of the Chinese maritime customs, may be taken as fairly typical of the prewar years and the first few postwar years in spite of the disturbed political conditions.

Of the total shipping engaged in 1947, 41,733 were steamers with an aggregate tonnage of 18,331,569 and 23,006 were Chinese junks with an aggregate tonnage of 1,701,722. These figures were considerably below prewar figures.

An important feature shown by Tables I and II is the considerable excess of imports over exports; with the exception of certain years in the 1880s, this was a constant characteristic of Chinese foreign trade from 1869. The interpretation of this excess is by no means easy. It cannot be explained, as in the case, for example, of Great Britain, by so-called "invisible" exports in the form of shipping services paid for by imports or by interest on capital invested abroad, which again swells the import list. China has, however, an important asset, which is in some respects comparable with the latter, in the extensive remittances made to their ancestral homes by emigrants (numbering more than 10,000,000) to Thailand, Malaya, Indonesia, Indochina, Burma, the Philippines, the Americas and Europe. But, important as this factor is, it does not seem sufficient to cover what the official returns describe as an "unfavourable balance."

Before 1918 China was bound by a number of unfavourable treaty agreements. After 1918 the organization of Chinese foreign trade entered on a new and momentous phase. By the treaty of Versailles Germany surrendered its concessions at Hankow and Tientsin, and the U.S.S.R., too, as a result of World War I, lost and later renounced its treaty privileges. At the Washington conference (1921–22) the nine-power treaty on the Chinese customs tariff decreed *inter alia* "a general revision of the tariff, to make it a more effective instrument of revenue." In 1925 and 1926 an international conference was held in Peking to deal with the problem of the tariff. In 1928, 1929 and 1930 all the powers, including Japan, consented to the resumption by China of tariff autonomy. In 1929 China made these agreements effective by inaugurating a system of duties fixed by itself.

After the Japanese occupation of Manchuria in 1931 and especially after the Japanese attack on China in 1937, China's foreign trade was greatly modified by the progressive Japanese aggression. More and more Japan endeavoured to bring within its economic empire the portions of China which it occupied. Japan did this in part through various companies organized specifically for this purpose. Obviously Japan's plan was to integrate all of east Asia into an economic whole in which it would be dominant and in which Chinese economy would be made to subserve Japanese ends. As the war progressed, Japan strove by the slow strangulation of an increasing blockade to cut off from the outside world Free China. By successive steps various Chinese ports were seized, access from west China to the sea by way of Indochina was cut off, and the capture of Hong Kong and the conquest of Burma in 1942 shut these doors to the outside world. By 1943 such foreign trade as Free China had was either by air transport from India or through the Japanese blockade. During these years no reliable figures on trade could be had.

China had a big import surplus in 1946 and 1947 which was financed largely by foreign aid. The composition of imports to China in those years changed considerably as the result of deliberate policy. In the 1930s, rice and wheat headed the import list. In 1947 raw materials (mainly raw cotton), capital goods and chemicals headed the import list. In exports, wood oil had become increasingly important.

Foreign trade in 1948 was considerably reduced because of civil strife but began to increase in 1949 under the Peking government. Various measures of import and export control were adopted, such as the state monopoly in the export of bristles, soybeans and mineral oils, and the allocation of foreign exchange for the import of machinery and essential raw materials.

After 1949 the direction of foreign trade of the mainland of China shifted considerably, reflecting developments in the political and economic structure of the area and in the international situation. Imports from the United States decreased considerably in 1949 and 1950. Imports from the United Kingdom also decreased, but imports from Hong Kong increased substantially, since Hong Kong, more than during earlier years, served as an entrepôt for the mainland of China through which commodities were imported from other countries with which the Peking government had strained diplomatic relations. In Dec. 1950 the United States announced the ban on transportation or discharge

TABLE I.—*Foreign Trade of China, 1933 and 1947*

Principal commodities imported directly from abroad				
Commodity	1933		1947	
	In thousands of standard $	Per cent	In millions of Chinese national $	Per cent
Rice	150,272	11.2	187,443	1.7
Kerosene oil, liquid fuel and lubricating oil	115,435	8.6	993,253	9.3

Others	244,198	39.9	3,291,530	51.6
Total net exports	611,828		6,376,504	

The equivalent of the standard dollar in terms of the U.S. dollar in 1933 was 0.26347 and of pence sterling 14$^{15}/_{16}$. The equivalents of Chinese national $1,000 in terms of U.S. currency in the months of 1947 varied from a high of U.S. $0.29674 in January to a low of U.S. $0.0128 in December, and the average for the year was approximately U.S. $0.09.

TABLE II.—*Foreign Trade of China with Principal Countries, 1933 and 1947*

Country	Direct imports	Percentage of total imports	Direct exports	Percentage of total exports	Excess of Imports	Excess of Exports
	1933, in thousands of standard $					
United States	296,101	22.01	113,065	18.48	183,036

Other ports	19.10	8.62

by U.S. ships or aircraft of strategic materials shipped from or transhipped through the United States to the Chinese mainland, Hong Kong and Macao. Subsequently trade with the Soviet Union and the eastern European countries increased considerably.

Trade with the Soviet Union was only 0.4% of total trade in 1936 and 8% in 1949. Trade and credit agreements were signed with the Soviet Union in February and April 1950. In 1950 the Soviet Union accounted for 19.84% of total imports and 26.58% of total exports; in 1951, 44.70% of total imports and 51.51% of total exports. Trade agreements were also signed with eastern European countries such as Poland, Czechoslovakia, Hungary and eastern Germany. These countries accounted for 1.37% of total imports and 3.87% of total exports in 1950; in 1951, for 25.30% of total imports and 26.43% of total exports. Imports from the Soviet Union and eastern European countries consisted mainly of industrial raw materials, industrial machinery, equipment and parts, and communication and transportation equipment and parts. Exports to those countries consisted of soybeans, silk, tea, wool and agricultural by-products.

In Formosa, most of the import and export business before and during World War II was with Japan. After the war, the Chinese mainland was Formosa's supplier-buyer. However, in 1949 Formosa lost this market.

In Dec. 1949 private trading was resumed between Formosa and Japan. Of the U.S. $93,000,000 exports in 1951, purchases by Japan amounted to U.S. $38,790,000, including sugar, rice and tea, and out of the imports of U.S. $84,000,000, Japan supplied U.S. $39,920,000 worth of commodities.

COMMUNICATIONS

Transportation.—In modern times for the most part freight was still moved in China as it always had been, by human labour, with animals as supplementary carriers. The wheelbarrow and carrying pole are the commonest means of transport for small merchandise. In north China wheeled vehicles, mostly the springless Pekingese cart, are used to a considerable extent on the sandy tracks, while in the centre and south the sedan chair is still in evidence, and rickshas are in general use in and around the larger cities. The Tsinlingshan roughly defines the northern limit of the general use of water transport, which in north China becomes subordinate to the cumbrous cart, drawn by horse, mule, bullock or mixed team. In the utilization of inland waterways no people have excelled the Chinese. The natural routes provided by the Yangtze and its great tributaries and to a lesser extent by the Si Kiang and other rivers of southeast China bear an enormous amount of junk traffic, while steamboats, large and small, increased especially in the lower Yangtze.

From an early stage of Chinese history the rivers have been supplemented by canals. The most famous of these was the Grand canal, at its fullest development reaching from Tung-chow, just outside Peking, to south of the Yangtze. In later years much of it suffered from accumulations of silt and lack of repair. In central and south China the great bulk of inland trade is carried on by waterways, and many millions of Chinese spend their lives in boats. At various periods of Chinese history extensive systems of "imperial" highways were constructed, radiating from the capital, but these were seldom kept in repair for long and most became mere tracks. However, after the "good roads movement" was launched in 1921, broad macadamized thoroughfares, capable of carrying heavy traffic, were constructed around many of the more progressive cities. Motor services came into existence, and highways were increased from 1,185 km. in 1921 to 115,702 km. in 1936. By 1950 the 200,000-km. mark was reported to have been passed. Most of these roads had only dirt surfaces, but some had been given rock dressings. Notable was a road which, under the pressure of military necessity, the Chinese built from Yünnan to Burma.

Passenger and freight transport by air were also developed after 1929. It was both retarded and stimulated by the war with Japan.

Railways.—The program of railway construction, which in the early years of the 20th century was making fair progress, was almost entirely held up during the 1920s because of civil war. It was resumed in the 1930s.

After 1937 some old railways were destroyed during the war while new ones were being built. Under the Communist regime railway construction continued to progress. All in all, the total length was approaching the 30,000-km. mark, which was, however, a low figure for a country like China. The outstanding feature of the railway system, so far as it has been completed, is the concentration in north and northeast China and the lower Yangtze valley. Thence diverge:

1. The Peking-Kalgan-Suiyuan-Paotou line, which ascends the scarps leading to the high Mongolian plateau and is intended to develop the pastoral and potential agricultural resources of Inner Mongolia and northwest China. This line is notable as having been constructed and maintained by the Chinese without external assistance.

2. The two great trunk railways traversing the plain of north China from north to south: (*a*) the Peking-Hankow railway (1,215 km.), whose route lies along the western border of the plain, and, with the equally long line from Hankow (terminus at Wuchang, across the Yangtze from Hankow) to Canton (1,096 km.), forming the north-south artery par excellence; (*b*) the Tientsin-Pukow railway (1,010 km.), running through the eastern part of the plain, links Peking with the Shanghai-Nanking line and the lower Yangtze valley.

3. The Peking-Tientsin-Mukden railway, traversing the coastal sill between the edge of the Mongolian plateau and the sea, joins the two great northern centres with the metropolis of south Manchuria and makes contact with the complex and rapidly expanding railway system of Manchuria. (Manchurian railways total about 12,000 km., including the Chinese Eastern and the South Manchuria railways which were merged after World War II

as the Chinese Changchun railway jointly managed by China and the U.S.S.R. until Dec. 31, 1952, after which it came under full Chinese administration.)

The most important transverse line is the east-west Lunghai railway (1,227 km.), which from the port of Lienyün in northern Kiangsu crosses both the north-south trunk lines and runs through Süchow and Kai-fêng to Loyang, Sian and Paoki. Continuations were projected to Lanchow-fu, in Kansu, and to Chêngtu, in Szechwan. (Construction was under way in 1953.)

Apart from small branch lines, mainly tapping coal fields, there are two important railways connecting with the main systems: the Shantung railway joining Chinan on the Tientsin-Pukow line with the seaport Tsingtao (Kiaochow), and the Shansi railway linking the Peking-Hankow line with Tai-yuan.

Shanghai is the focus of a distinct system: (1) Shanghai-Nanking, (2) Shanghai-Hangchow Ningpo and (3) Shanghai-Woosung (the first railway built in China, 1876).

From Hangchow a railroad stretches westward through Nanchang and Changsha and was projected to reach Kwei-yang and Kunming. Kiukiang on the Yangtze was connected with Nanchang. Hengyang on the Hankow-Canton line in Hunan was connected with Kwei-lin in Kwangsi.

In the south, Canton has a similar role. Apart from the Canton-Hankow line, already mentioned, short railways connect the southern metropolis with Kowloon, opposite Hong Kong, and with Samshui. Another important railway in China is the trunk line, completed by the French in 1909, which runs from Haiphong in Indochina to Kunming in southwest China, part of its course being in Chinese territory. There are short local lines running inland from Amoy, Swatow and Macao, respectively. The railway between Chêngtu and Chungking (823 km.) in Szechwan was completed in 1952. Work was begun on a number of other lines in west China designed to connect some of the main cities in Szechwan and Yünnan, and Kweichow with Hunan.

Postal Services.—The postal service of China began in 1879 and was greatly improved after 1889. As a result of the Washington conference and in acknowledgment of the efficiency of the Chinese postal service, all the foreign powers concerned agreed to withdraw their postal agencies from China on Jan. 1, 1923.

Postal service was maintained with surprising efficiency in spite of civil and foreign wars. Wireless and telephone services are fairly widely distributed.

ADMINISTRATION

Sun Yat-sen's Three Principles.—After the revolution of 1911, which abolished the imperial office and the time-honoured machinery of administration, China passed through a bewildering series of political changes and civil wars (*see* under *History*). On the eve of the outbreak of the Chino-Japanese hostilities of 1937 a quieter phase had supervened and constructive forces were obviously at work, but the factors in the political situation were still extremely complex and the legacy of militarism which the civil wars had bequeathed increased the difficulty of administrative reconstruction. In 1928 a constitution was promulgated embodying certain principles to which, in theory at any rate, all Chinese Nationalists adhered. The constitution and the administrative arrangements which it contemplated were the work of the Kuomintang or the Nationalist party, which was not only supreme in China at that time but was the only party whose existence was recognized. Sun Yat-sen, the founder of the Kuomintang, was after his death regarded in some sense as its patron saint, his will or statement of three essential principles being regarded as a kind of instrument of government. The Three Principles of the People have been translated as:

1. Nationalism (national emancipation and racial equality).
2. Democracy (political rights for the people).
3. Livelihood (economic welfare of the people).

Under the first principle Sun states what is necessary for the development of a strong national consciousness so that China can escape from the position of being "a colony of every Great Power." One of the steps on which he insists is that "we must organize our people into one strong organic group. This can be accomplished only by utilizing such strong units as clans and local organizations." Many old characteristics must be revived, including "our old learning as found in the *Great Learning*" and "we must revive our creative power, the power which we once had in inventing new things." He adds, "We must do all these things, but, aside from that, we must also go out to learn what is best in the West."

Under the second principle Sun first states the case for democracy and maintains that China in this respect has little to learn from the west, since "the West has, in the last century, progressed much more rapidly in material things than in those that concern man and his welfare. In politics, very little advance has been made." He makes the interesting point that whereas the western peoples had formerly too little personal freedom and had to fight hard for liberty, in China "our people have had too much personal freedom" and, as a result, "have become a plate of sand . . . helpless in the face of foreign imperialism and its economic conquest." "So what we need now is not to fight for more personal freedom, but to sacrifice some of our personal freedom, in order to gain our national freedom." China has to face two problems, in the solution of which, he maintains, it is helped neither by its own nor by western experience: how to have a strong central government and at the same time to remove the fear of the people of such a government. To build up a powerful government machinery and to enable the people fully to exercise their power and control of the machinery two things are essential: (*a*) the organizing of government "on the five principles—legislative, judicial, executive, entrance to public office by examination, and censorship"; (*b*) safeguarding the people with "the power of election, power of recall, power of initiation of new laws, and power of revision or abolition of old laws."

Under the third main principle Sun insists that "we must centre all our problems around the welfare of the people" and avoid the western mistake of taking "material problems as the central point in human history." "None of the forms of Socialism developed in the west are fitted for our own country." China has to avoid the dangers of industrialism. "Our great and immediate problem is not economic inequality but economic poverty, not a fight against capitalists, but the prevention of the rise of capitalists in the future. Our method of solving this problem is to develop State industry."

He enumerates a series of measures for increasing production and concludes: "On the one hand there is an urgent need of improving our old methods of raising raw materials. On the other hand, we have to develop our own textile industry as rapidly as possible. This is at present hindered by the treaties which forbid us to have tariff autonomy. So our first step in solving the problem (of clothing) is to remove all unequal treaties so that we may carry out a policy of protection."

The official program of the Kuomintang, passed at a plenary session of the central executive committee, with delegates from all provincial committees, in Oct. 1926 at Canton, was essentially an elaboration of the main points and an application of the abstract principles contained in the famous will.

Nationalist Constitution.—Sun Yat-sen contemplated three stages in the political development of the country. The first was to be military rule. This was to be followed by political tutelage under the Kuomintang, and this in turn was to be succeeded by government under a constitution which presumably would be democratic. In theory, the first stage ended in 1928. In practice, military and party rule went along together. The Kuomintang brought together in Nanking a national assembly which adopted the constitution of the Republic of China on Dec. 25, 1946, based on Sun's teachings. In general the structure of government provided for in that constitution was maintained by the Nationalist government on Formosa in the early 1950s after that government was driven from the Chinese mainland in 1949. The following are the chief features of the organization of the National government as stipulated by the constitution:

1. The president is the head of the state, elected once in six years, vested with supreme power. He controls the army, navy and air force and is alone competent to declare war, conclude peace and negotiate treaties with foreign states. He represents the nation in international affairs and at the same time is commander in chief of all the forces.

2. Five yuan (or councils) for the following functions: executive, legislative, judicial, examination and control (*i.e.*, censorship or supervision). Of these the executive yuan is the highest administrative organ of the national government, composed of ministries and commissions to which are entrusted various executive duties. The president of the executive yuan is nominated and appointed by the president with the consent of the legislative yuan. Members of the legislative yuan are elected once in three years and members of the control yuan once in six years. It will be observed that the five yuan or councils are in accordance with Sun's proposals under his second essential principle. The control yuan exercises the functions of the censorate under the imperial regime. The examination yuan supervises the system of public examinations as the test of admission to public office, which was originated in the 7th century.

Communist Government.—The Peking government was inaugurated on Oct. 1, 1949, under the name of the Central People's government. The leaders of the new government drew upon Marxism-Leninism-Stalinism for inspiration and patterned some of their techniques of government after those worked out by the U.S.S.R. The following are the chief features of the organic law of the Central People's government of the People's Republic of China, passed by the first plenary session of the Chinese People's Political Consultative conference (P.P.C.C.) on Sept. 27, 1949:

1. A government council consisting of a chairman and six vice-chairmen and 56 members, elected by the P.P.C.C., "represents the People's Republic of China in international relations, and assumes leadership of the state authority at home."

2. The council controls four organs, namely (*a*) state administration council, (*b*) people's revolutionary military council, (*c*) supreme people's court and (*d*) people's procurator-general's office. The state administration council consists of a premier, a number of deputy premiers, a committee on political and legal affairs, a committee on finance and economics, a committee on culture and education, a committee on people's supervision and 30 ministries, bureaus, offices and commissions.

Under the Peking government there were established six large regional divisions, two autonomous governments (Inner Mongolia and Tibet), 28 provinces, eight administrative districts and 13 municipalities placed directly under the control of either Peking or the administrative regions.

EDUCATION

A national system of education was first established during the last years of the Manchu dynasty, but it was reorganized under the republic. The school system was organized as follows:

1. A two-year kindergarten.

2. A six-year primary school course (covering approximately the ages 6 to 12) divided into two grades, lower and higher, the former of four years' and the latter of two years' duration. In theory this was obligatory. In Formosa there were 1,289 primary schools with an enrolment of 976,462 in 1952. The ratio of the number of children attending school to the number of children of school age reached 81.40%. On the mainland there were approximately 450,000 primary schools with an enrolment of 38,700,000 in 1952, estimated to be about 50% of the number of children of school age.

3. A six-year middle or secondary school course (age 12–18), similarly divided into senior and junior grades, the higher tending to be vocational in character. In Formosa there were 129 middle schools with an enrolment of 85,682 in the spring of 1952. On the mainland there were 4,015 middle schools with an enrolment of 1,290,000 in 1951.

4. A four-year university course. There are also normal schools, both lower and higher, for the training of primary and middle school teachers, respectively, and also higher professional or technical colleges of various types.

In Formosa there were one national university, three provincial colleges and three polytechnic institutes with a total enrolment of 7,965 in 1952, as compared with 2,983 in 1947 and 5,906 in 1950. On the mainland there were 218 institutions of higher education with an enrolment of 219,700 in 1953, as compared with 129,000 in 1946.

A complete reorganization of higher educational institutions was undertaken on the mainland after 1951. In big cities such as Shanghai and Peking the old universities were in some cases divided up and in others combined so that each administrative region had only one university for the arts and sciences. In 1953 there were 13 universities in different parts of China; 20 polytechnic institutes, formed by rearranging the technical colleges of the old universities; 26 newly established special technological institutes, such as the steel institute and the mining institute; 29 agricultural forestry colleges; seven institutes for finance and economics; two special colleges newly established in the northeast and in Sinkiang to train students from the national minorities; and other special institutes. As the result of government policy, students majoring in technology rose to 35.4% in 1952 as compared with 18.9% in 1946.

CHINA (ware): *see* CHINAWARE.

CHINABERRY (*Melia azedarach*), a member of the Meliaceae or mahogany family and also known as China tree, pride of India and Indian lilac, is a spreading, mostly deciduous tree that may reach a height of 50 ft. The leaves are twice pinnate, the fragrant, purplish flowers are in open panicles 4–6 in. long, and the fruit is a globular, yellow, smooth drupe to ¾ in. in diameter, hanging after the leaves fall. Although native to Asia it has become naturalized in tropical America and is much grown in the southern United States from southeastern Virginia to Texas. It grows with great rapidity and forms a desirable, dense shade. The variety *umbraculiformis*, known as the Texas umbrella tree, has drooping foliage and radiating branches which give the tree the appearance of a giant umbrella. (J. M. Bl.)

CHINA CLAY (KAOLIN), an essential ingredient in the manufacture of china or porcelain. The word "kaolin" is derived from the Chinese Kau-ling ("high ridge"), a hill east of King-te-chen, whence the earliest samples of the clay sent to Europe were obtained by François Xavier Dentrecolles (1662–1741), a French Jesuit missionary. His specimens, examined in Paris by R. A. Ferchault de Réaumur, showed that true porcelain was manufactured from a paste containing two essential ingredients: china clay, a pure white clay; and china stone, a variety of granite consisting mainly of orthoclase feldspar. The china clay confers plasticity on the paste and secures retention of form for the ware when exposed to the heat of the kiln; the china stone gives the characteristic translucency. Some of the earliest discoveries of china clay in Europe were at Aue, near Schneeberg in Saxony, and at St. Yrieux, near Limoges in France. In England it was discovered in Cornwall about 1750 by William Cookworthy of Plymouth, who in 1768 took out his patent for making porcelain from china clay and china stone. These raw materials were found first at Tregonning hill, near Breage, and afterward at St. Stephen's-in-Brannel, near St. Austell; and their discovery led to the manufacture of true porcelain at Plymouth and subsequently at Bristol.

The china clay rock of Cornwall and Devon is a granite with its orthoclase feldspar decomposed to a soft, white, powdery substance which, when wet, acquires the characteristic plasticity of clay. The other components of the granite, the quartz and mica, are unaffected, and although they are subordinate to the decomposed feldspar or kaolin their presence retains for the rock the appearance of a weathered granite. Although kaolinization can undoubtedly result from weathering, the evidence in this case indicates that the alteration consists in the removal of the alkalies and the formation of a hydrated silicate of aluminum having the formula $Al_2O_3.2SiO_2.2H_2O$. This substance, known as kaolinite (*q.v.*), constitutes the bulk of refined china clay, the impurities of the commercial article being finely divided quartz and mica (muscovite). It is not possible to remove the whole of these impurities by washing, and this accounts for the difference in composition between pure kaolinite and a refined Cornish clay as shown by the analyses below.

	Kaolinite	China clay
SiO_2	46.3%	48.3%
Al_2O_3	39.8%	37.6%
Fe_2O_3		0.5%
CaO		0.1%
K_2O, Na_2O		1.5%
H_2O	13.9%	12.5%

Note: 1% of alkalies in china clay is equivalent to 8.5% of muscovite.

Physically china clay is a white, soft powder consisting of crystals and groups of crystals which may be observed in the electron microscope and which range in size from 0.2 μ to 50 μ across, the larger size in the form of composite columns of crystals called vermicules from their appearance in the optical microscope. According to the degree of refining, a china clay

may contain all its particles below 3 μ or below 50 μ. It will form with water a smooth mixture whose viscosity may be greatly influenced by the presence of certain deflocculating salts, particularly silicates and phosphates, which permit concentrations up to 70% of solids to be achieved in some cases. This property has commercial significance in the ceramic industry in the casting process and in the paper industry in high-speed paper-coating processes. The whiteness of china clay, a property important in most of its uses, is largely dependent on the absence of iron as an impurity. The qualities for which china clay is esteemed in the arts vary according to the application of the material. In the paper industry it is used as a filler for paper where whiteness combined with a medium grain size providing high retention in the fibres together with absence of abrasive impurities are required. In the coating of paper very white, fine-grain china clays are used generally in combination with other minerals in the classical brush-coating processes and alone in the high-speed machine-coating processes. China clay is much used in ceramics and forms the refractory basis of the article during the sintering or firing process. In all ceramic composition it contributes to the plasticity in the unfired state and, in compositions containing no other clay, is the main source of plasticity. It is widely used as a refractory. In the associated mineral china stone, the feldspar is only partially decomposed, and the higher percentage of alkalies leads to its employment as a flux in combination with china clay to produce a ceramic body. By such combinations vitreous ceramic materials such as porcelain and bone china are produced at temperatures substantially lower than the melting point of china clay itself. China clay has a lesser though widely distributed use in a variety of industries, the next important to the above being the rubber industry, in which it is used as a filler and reinforcing agent.

In order to prepare china clay for the market the china clay rock is subjected to the action of a water jet; the bulk of the quartz and any undecomposed feldspar are arrested in sand pits, which, in their modern form, are mechanically operated. The slurry is pumped to the surface of the pit, which may be 250 ft. deep and several acres in area. After further separation of coarser impurities, various particle-size classification processes are applied, resulting in a series of products in the finest of which 80% of the particles may be less than one micron in diameter. The refined clay, as a suspension in water, is then led to settling pits or tanks, in which the clay concentrates and water is removed. The concentrate is filter-pressed to reduce the water content and then dried in mechanical driers. A number of chemical and physical refining processes will have been applied to special types of clay to suit the properties to particular purposes. China stone is quarried and ground without levigation.

(F. H. HA.; N. O. C.)

UNITED STATES

In the United States the term "china clay" and "kaolin" are synonymous. They designate relatively pure clays of highest quality which fire white or nearly white. Either residual (primary) or sedimentary (secondary) kaolins were reported in 24 states in the mid-1950s. Major production was concentrated in Georgia and South Carolina, Georgia alone accounting for more than 70% of the domestic production of nearly 2,000,000 tons yearly. Other producing states included Alabama, California, Florida, Illinois, North Carolina, Pennsylvania, Texas, Utah and Virginia. Also of interest are the extensive ball clay deposits of western Kentucky and Tennessee. These fine-grained, extremely plastic clays, closely related to kaolins, are consumed almost entirely by the ceramic industry.

The extensive kaolin deposits of Georgia and South Carolina occur on the coastal plain in an irregular belt along the fall line. These beds of sedimentary kaolin are 5 to 40 ft. thick, with up to 60 ft. overburden. Dry Branch and McIntyre, Ga., and Aiken county, S.C., are major production centres. Georgia kaolins tend to be more fine-grained and plastic than South Carolina kaolins. Open-pit mining is employed, and the yields from processing the Georgia and South Carolina kaolins range from 80%–99%.

The commercial Florida kaolins occur in Putnam county in a sedimentary rock stratum about 10 feet below ground level at about the water table. Hydraulic mining is thus logically employed. The deposits yield roughly 15% clay and 85% sand and gravel. The commercial kaolin separated in processing is fine-grained and very plastic, often being termed ball-kaolin.

The residual North Carolina kaolins are mined principally in mountainous Avery and Mitchell counties. These kaolins occur in dikes and lenses resulting from decomposition of pegmatite granite. The average depth of the kaolin mines, excluding overburden, is about 40 ft. A yield of about 15% commercial kaolin plus some by-product mica results from processing.

In the United States most of the kaolins are produced in several grades, ranging from crude lump clay to air-floated material. The wide differences in the raw kaolin itself, plus variations in refinement and sizing, accommodate all reasonable market demands. Refining and beneficiating processes range from air separation of dry-ground raw kaolin to elaborate water washing, separation, settling, classification and chemical treating.

The paper industry uses half of all kaolin produced, for filling and coating purposes. The other half is consumed primarily for rubber filling and ceramic products (refractories, whitewares, cement, vitreous enamel, etc.), with some being used in oil refining, fertilizers, insecticides, chemicals, paint and linoleum.

CHINAN or TSINAN, a large and historic city and the capital of the province of Shantung in north China, 36° 43′ N., 116° 37′ E. Chinan is situated at the northern base of the ancient highlands of Shantung (near Tai-shan, the sacred mountain) where they sink beneath the alluvium of the Hwang-ho and along an important spring line which fostered very early settlement. Its early history is bound up with that of the ancient states of Chi and Lu in the classical (Chou) period; when the present province of Shantung—closely corresponding to the territory of the two feudal states—was created under the Ming dynasty (1368–1644), Chinan, a natural focus of mountain and plain, was selected as administrative centre. The change in the course of the Hwang-ho in 1854 brought it within 5 mi. of Chinan. But the destruction of the dikes as a war measure in 1938 turned most of the water into the regions south of Shantung, while in 1943 the Japanese military began work to divert the Hwang-ho north into the Wei river. Formerly, Chinan controlled the Hwang-ho bridge of the Tientsin-Pukow railway (completed 1912). This railway runs parallel to, and fulfils the function once served by, the now dilapidated Grand canal. Chinan is the junction of this arterial railway with the Shantung railway running eastward by way of the Poshan coal field to the port of Tsingtao on Kiaochow bay, which from 1898 until 1915 was leased territory in control of Germany, afterward falling into the hands of Japan. Although by the Shantung treaty, arranged at the time of the Washington conference (1922), Japan on certain conditions surrendered Tsingtao to China, its influence and interests in the Shantung railway were still very strong, as was shown by the dispatch of Japanese troops to Chinan in 1928, when the Nationalist armies were advancing northward. In contact with foreign influences along the two railways, in communication with the sea by a canal fed from the local springs and the market for one of the richest parts of the great plain, Chinan was much affected by western industrial methods, seen especially in flour milling and cotton manufacture. The city was voluntarily opened to foreign commerce in 1904, and a large "settlement" grew up in the Shang-pu or trading quarter, outside the west gate of the city. Pop. (est. 1936) 472,300.

Occupied by Japan from 1937 to 1945, Chinan was captured by Communist forces in 1948.

CHINANDEGA, an important city of Nicaragua, Central

America, capital of the department of the same name. It is 13 mi. N.N.E. of the Pacific port of Corinto, on the Pacific railway: population (1950) 13,146. It is 22 mi. from León and 74 mi. from Managua, the national capital. Chinandega is the centre of the sugar-producing area of Nicaragua and a high grade of sugar is manufactured and exported to the western United States and to other Central American countries. Corn, rice, potatoes, vanilla and cotton are also grown.

Chinandega was partly destroyed by fire during one of the battles of the revolution of 1927 in which American marines and aeroplanes took an active part.

CHINAWARE, a name given to a hard, translucent type of pottery.

Earthenware is sometimes quite thin, and it is a common error not to discriminate between this and the ware which is properly called china.

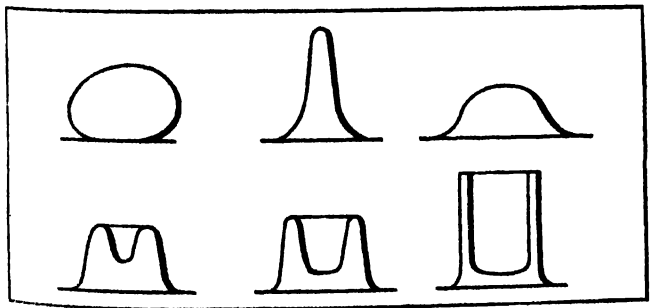
A simple test for china is its translucency, which allows the outline of a finger to be seen if held between a piece of ware and the light.

Another and more accurate test is that of applying red ink to the ware under the glaze. If the ink is absorbed, then it is considered that the ware is not china. A portion of the glaze must be thoroughly removed before the ink can be applied.

The actual meaning of "vitrified" causes some trouble and the following is the definition: vitrified pottery is nonporous; unvitrified pottery is porous. Vitrified china has been defined as follows: vitrified china is glazed chinaware having a white body and burned to such a temperature that a dense, practically non-absorbent body is produced.

"Practically" is a much abused adverb, and one is left wondering whether or not a slightly absorbent ware with a white body would pass as vitrified.

Porcelain, which may be regarded as synonymous with china, is not easily defined in scientific terms, for several specimens of ware which may be correctly regarded as true porcelain, will vary in actual composition.



J. W. Mellor, F.R.S., said that the most practical definition he could give is the following: "Porcelain is a body which in moderately thin layers is translucent."

CHIEF CENTRES OF PRODUCTION

Commercially, the chief centres of production, with international importance, are the potteries of Limoges, Fr., Staffordshire, Eng., Czechoslovakia, Germany (Thuringia and Bavaria) and Japan. Copenhagen, Den., produces a very fine china, but this, although sold commercially, is not strictly a competitive production.

England.—Bone china, the porcelain in which bone ash is an important constituent, is made almost entirely in England, and it is claimed that it is more durable than the feldspar china of the continent of Europe.

This type of porcelain was introduced by the famous potter Josiah Spode of Stoke-on-Trent in 1799. Alexandre Brogniart, director of the national factory at Sèvres, referring to this, said:

FROM BLIN, "POTTERS' CRAFT" (VAN NOSTRAND)

PROGRESS OF A BALL OF CLAY ON THE POTTER'S WHEEL

"He produced a better porcelain than any that had yet been made in England. He endeavoured to equal the soft porcelain of Sèvres, which his paste closely resembled. He introduced, or at any rate perfected, the use of calcined bones in the body of the ware."

Spode's formula was later adopted by all the leading manufacturers throughout the five towns in north Staffordshire, and also by the Coalport, Derby and Worcester factories. Of the manufacturers of china in England, the greater part have their factories at Longton, one of the five towns mentioned above.

Japan.—Some of the ware of Japan has a world-wide reputation and is distinctly oriental in its decoration; but the Japanese rapidly copied western methods, and the decorations of their commercial products are often distinguished from the wares of European countries only with difficulty. They realized that in order to sell in another country, they must decorate their ware to appeal to the taste of the potential buyers. The U.S. proved to be the best customer of Japan for porcelain.

The cheaper types of china are made in the area of Nagoya, but the Imari porcelain (a very high-class product) is produced at Arita. Toy tea sets and dolls are important items in the Japanese porcelain trade, and the annual production of these wares is great. Porcelain insulators are also exported in large quantities, and many users of wireless materials will probably have handled this particular ware.

RAW MATERIALS

The raw materials needed for the manufacture of china are china clay or kaolin, china stone, bone and feldspar. (*See* CHINA CLAY.)

China Stone.—This is an important ingredient in the china body, and it is mined by inserting explosive charges in holes drilled by compressed air boring machines.

The stone has four recognized qualities or grades: hard purple (a white, hard rock with a purple tinge); mild purple (similar but softer); dry white or soft (a soft white rock); buff (similar to dry white, but with a slight yellow tinge).

Silica is the principal constituent, amounting to more than 80% in the two purple and the buff varieties, and about 74% in the dry white. Alumina is the next important ingredient, amounting to about 18% in the dry white and from 7% to 10% in the other varieties. The most effective constituents are the alkalies and lime which make up the balance of the composition. China stone gives the china body its translucency resulting from its feldspar content. Its function, hence, is that of a flux.

Bone Ash.—This, as already stated, is used in the English china industry where the bone china is almost exclusively produced. Animal bones are used and, as a result of its vast business of cattle rearing and slaughtering, South America is the chief source of supply. The bones are calcined and ground to a fine powder.

Feldspars.—The feldspars are silica compounds of alumina and alkalis (chiefly potash and soda), with small proportions of iron oxide, lime and magnesia. Norway is a principal source of supply, but large quantities are also found in Czechoslovakia. Canada is an important feldspar-producing country.

The Norwegian feldspar is largely used in Europe. The mineral is exported both in lump and as a powder.

MAKING THE WARE

The Slip.—The slip, it should be explained, is the china clay and other ingredients mixed with water to a thin consistency. Metallic impurities, which would spoil the finished ware, are removed by a series of magnets, which, in one method, are arranged in what is known as a cascade; *i.e.*, the watery mass flows over small falls, the metallic parts being retained by the magnets and the remainder passing on. As the slip has to pass over a series of small falls in cascade fashion, any pieces of metal are certain to be extracted. (Prior to this process the various ingredients have been weighed and mixed in an agitator known as a blunger.)

The slip is, of course, too thin in consistency for moulding into ware, and must be made into a firm and plastic condition. This is done in a filter press, an appliance used in many trades. Briefly, this consists of a number of cloth bags in square frames, which are screwed together horizontally, the whole resembling a

"square" loaf, cut into slices, but retaining the shape of the loaf. By pressure, the surplus water is removed and the clay, now in flat slabs, is rolled up and passed on to the "pug mill." This piece of machinery may be likened to the domestic mincer or meat grinder. Blades, revolving in a manner popularly known as the "spiral," knead the clay and force it through a circular opening, from which it emerges as a huge "sausage."

In the pottery industry, as in all other artistic crafts, mechanical means cannot effectively replace the dexterity of man or woman. The "pug mill," *e.g.*, is an admirable method for kneading the clay, but it cannot do it so effectively as an experienced pottery worker. Such a man would cut a lump of clay into two pieces and bang one on to the other, a process which he repeats many times. Obviously this is a slower and more expensive method, and cannot be used for the cheaper types of ware.

Throwing.—The clay is now ready for making into the ware. Everyone has heard of the potter's wheel, but many have probably not seen one or have an incorrect impression of this simple appliance, which plays such an important part in the making of some delightful pieces of pottery. It is not a wheel, as generally understood, but a circular, horizontal disc, which revolves at the will of the thrower. A ball of clay is thrown on to the "wheel," and then the "thrower," after getting it into the condition of plasticity he considers most correct, deftly transforms the ball of clay into whatever shape he is proposing to make, by pressing it with his fingers as the "wheel" revolves. In this way a symmetrical form is obtained. The art of the potter is infinite, and it is little wonder that his skill in transforming an ugly ball of clay into a bowl or vase of beautiful contour has moved poets to acclaim his craft.

For domestic articles, such as cups, the thrower may be aided by a mould, which is made of plaster of paris. The inside of the mould will correspond to the shape of the outside of the cup. It is a simple matter—to the experienced thrower—to press the clay into the mould until the desired thickness is obtained. The plaster of paris absorbs some of the moisture in the clay, which, besides contracting, becomes correspondingly harder, and therefore much more easily handled by the potter. The cup is then passed on to a man who turns (or trims) it on a lathe. The cup, of course, is not complete without a handle, which could not be thrown on the wheel. It is therefore "cast," the clay taking the shape of a plaster of paris mould. After trimming, the handle is affixed to the cup by dipping the ends in some "slip." When joining together two pieces of clay, it is important to ensure, as far as possible, that the percentage of moisture is approximately the same in each, for if one is drier than the other, unequal contraction will take place, with the result that the two will part company. This is one of the many contingencies that the potter has to guard against, and it will readily be seen that a large amount of skill and experience is necessary for the production of good pottery.

Turning.—This important operation in the manufacture of pottery has been mentioned above. It will be obvious that the products from the thrower's hands will need trimming if a smooth finish is required. Some potters, particularly those known as "artist potters," who, however, usually work with coarser "bodies" (heavier types of clay), like to leave the marks of the thrower's hands, just as some take a pride in the hammer marks on hand-wrought silver ware. In commercial production, particularly if moulds are used, as mentioned in the previous paragraph, a little trimming is necessary. When the ware is moulded, a process that will be described later, turning will be an essential operation.

It must be remembered that the clay, when it reaches the lathe, is becoming harder; at this stage it is known as "green hard," a condition which has been likened to hard cheese, while another description is "leather hard." In such a condition the cup or other article can be shaved or trimmed on a lathe just as a piece of wood can. Any unevenness can be removed, while, if a "foot" for the ware is required, this can be formed by the turner. An additional advantage of the lathe is the speed with which the ware may be "embossed" with decorations, such as beads, etc. While the ware revolves, the turner presses against it a little wheel, which has the decoration engraved upon it, in reverse.

The lathe used for this work resembles in many respects the machine used for wood or metal turning. The principal difference is the method of holding the article to be turned. In the pottery industry, the ware is placed in a "chum," a hollow drum that grips the piece at about half its length. When the exposed half has been finished, the ware is reversed and the process continued.

In the case of cups, and other ware requiring handles, it will be obvious that the turning must be done before the handle is applied.

Jolleying.—Although the methods of the early potter have remained almost unaltered in many respects, the large output of the modern factories makes it necessary to provide a means whereby a more rapid production of ware can be maintained. The "jolley" takes the place, to some extent, of the thrower; but man's skill is still needed to ensure the output of good pottery. Again, we have a small revolving disk, and on this a mould of the exterior of the article to be made is placed. Into this a slab or "bat" of clay is thrown. The mould forms one side of the piece of ware (the exterior), and the interior is shaped by a "profile" which is brought down by a lever and cuts away the clay to the desired thickness, the mould on the platform being revolved during the process.

For flat ware, such as plates and saucers, the procedure is slightly different. Such pieces are made upside down, the bottom of the plate, or saucer, being uppermost. The mould in this case will furnish the shape of the interior or top of the ware, while the profile, which is lowered on to the revolving slab of clay by the lever, will form the underside.

When the piece of ware has been fashioned on this machine, it is taken, still on the mould, to a drying chamber. Here the clay contracts and the saucer, or whatever it may be, is lifted away and passed on for finishing. This means the trimming of the edges and smoothing with a flannel and fine sandpaper. It it should be a cup, a handle has, of course, to be applied.

Pressing.—This process consists of placing soft clay, which has been beaten out to the required thickness, into plaster of paris moulds, which may form one half of the ware. When the halves have been made they are brought together to form the whole, the joints being finished off. After sufficient water has evaporated, the ware can be removed, and handles, knobs, feet, or any other parts which have been fashioned in a like manner, are then attached.

Casting.—Many will have a passing acquaintance with this process, for the method of casting metals is well known; in the pottery industry the "slip" takes the place of the molten metal. The "slip" is poured into plaster of paris moulds, which absorb some of the moisture, leaving a layer of clay. When the clay is of sufficient thickness, the surplus "slip" is poured away, and the mould, with its clay lining, is taken to the drying room, where the ware contracts and hardens, making it suitable for removing and finishing off as in the case of pressed ware. The moulds may form only part of the finished article, the remainder being made in other moulds. When ready, the pieces from each mould are joined together. It will be seen that casting is similar to pressing, except that the potter is able to commence with an easily handled material (the "slip") which, owing to its limpidness or low viscosity, rapidly takes the shape of the mould. The process is therefore simpler and, consequently, cheaper. It is a method which lends itself admirably to the reproduction of figures and other modelled ware.

Mould-Making.—Plaster of paris moulds have been frequently mentioned in the various processes already described, and it will be useful to interpose here a brief description of the making of these moulds, as, undoubtedly, it is an important feature in modern pottery manufacture.

Plaster of paris is made from gypsum, a naturally occurring mineral composed of calcium sulphate. Gypsum is hydrated, *i.e.*, it contains a certain amount of combined water, which can be driven off by heat. When it has been calcined an amorphous powder is left, known as partially hydrated calcium sulphate, or plaster of paris.

This material has a peculiar property in that it swells when water is added, forming an absorbent solid, which lends itself

readily to the formation of various shapes by carving, turning on the lathe, etc. Every cup, jug, or other piece of ware produced, must, of course, have had an original from which it is duplicated. The original is modelled in clay and is solid, *i.e.*, it gives the shape of the *exterior* only. From this model the plaster of Paris mould is prepared. This is a process that needs special care, for upon the mould the accuracy of all the reproductions depends. The mould may be in three parts, two halves, forming the sides, and a bottom. From this mould a duplicate of the original can be produced, and, in turn, moulds for reproductions. The number of pieces of a mould will depend upon the shape of the article to be made.

Modelling.—As stated above, every piece of ware produced must have had an original, which may vary from an ordinary teapot to a dainty shepherdess, or a group of several figures. The modeller's skill in this matter may be likened to that of the artist who paints a picture for reproduction. The modeller creates and the craftsman copies.

But the task is not ended when the modeller has finished his work; considerable skill is required to reproduce his work faithfully. When the modeller's work takes the shape of a figure in fanciful pose, many moulds have to be made, and the number may be as high as 28. Arms, legs, hands, head and many other parts have to be moulded separately and then joined to make the figure created by the modeller. As the pieces are often hollow, it will readily be seen that great care must be exercised by the man whose occupation it is to assemble the various parts, as undue pressure on the pieces would cause distortion and the spirit of the modeller's art would be lost.

A further difficulty, which affects the modeller, is that allowance must be made for contraction. The mould from his model will, of course, give a piece of ware corresponding, in its raw state, to the original; but when the reproduction has lost its moisture and has been further contracted by the firing, the figure (or whatever it may be) will be much smaller. This shrinkage may be as much as one-tenth. Obviously the modeller must keep this in mind when at work on an original.

Firing.—The processes described have led up to the first firing of the ware, when what is known as "biscuit" is produced.

The shape of a pottery oven, or kiln, will be familiar, by photographs and drawings, to many. The huge, bottle-shaped ovens are peculiar to the pottery industry. They are heated by fires placed at intervals at the base. Coal is the fuel principally employed, but electrically heated ovens have made an appearance, while oil and gas have their advocates. On the Continent and in the Far East wood often plays an important part in the firing.

As thousands of pieces of ware may be fired at one time, the arrangement in the oven needs special care. It would not, of course, be possible just to stack clay cups on top of one another; even if they kept in position, the weight on those below would, at least, cause distortion. The ware is therefore placed in "saggars." which are largely fireclay receptacles resembling big cheeses in shape. In these the "green" ware is placed, separated by ground flint, which, owing to its very high melting, or fusing point, will not affect the ware in the oven. The "saggars," when filled, are "placed" in the ovens, special care being taken to see that they are perfectly level. As a rule, hollow ware (such as cups) is placed at the top of the oven and flat ware (such as plates) at the bottom. When filled, the ovens are sealed up and the heating is commenced, continuing for about 50 to 60 hours. For the first 24 hours the firing is slow, *i.e.*, the temperature is not raised unduly, to drive out the moisture. The temperature will then be increased until it reaches about 1,300° C. A necessary precaution is to ensure that the temperature never falls back. This is part of the fireman's responsibility; he must also know when the firing is complete. He has means of testing the rate of progress of the firing, but the control of the temperature and the length of time given needs skilful judgment. Very useful pyroscopes for determining the proper heat treatment attained in an oven are employed frequently. Some are small tetrahedra, called cones, compounded from a series of ceramic mixtures. These cones are placed in the oven where they may be observed by the fireman. As a certain temperature is reached, depending somewhat on the rate of temperature increase, they bend so that the apex gradually touches the base. The finishing point of the firing may thus be indicated. These pyroscopes are called Seger cones after their inventor. Other temperature indicators are Holdcroft's thermoscopes. These are small bars supported at their ends in a horizontal position. When the critical temperature of a bar is reached it sags in the middle. The Seger cones and Holdcroft's thermoscopes are given a variety of numbers, the refractoriness of the cone or bar increasing as the numbers go up. Pyrometers, scientific instruments for measuring heat, may be employed instead of the pyroscopes. When the firing is complete the oven is allowed to cool; this takes about the same time as the firing—50 to 60 hours.

The biscuit ware, when it leaves the oven, must be translucent, and it is the aim of all the makers to obtain a ware with a perfect translucent body, free from blemishes.

Glazing.—When the "biscuit" ware produced by the first firing has been sorted (for the rejection of any pieces containing flaws), and cleaned, it is ready for the "dipper," the man who dips the piece into a tub of glaze. The glaze is made from a variety of ingredients which, when fused, form what might be termed "glass," for the glaze on a piece of china is really a glass. Lead is an important ingredient in many glazes and the question of lead poisoning has long been a problem in the pottery industry; but this is being overcome by the introduction of low-solubility glazes.

It may appear a simple matter to dip a cup into a tub of glaze, but here, as in most of the processes through which the ware has to pass, the skill of the worker is all important.

The ware, with its coating of glaze, has now to be fired again, when the opaque covering will be rendered translucent. The china is arranged in saggars, the round, cheese-shaped, fireclay receptacles already mentioned, but this time the saggar will be glazed inside, otherwise trouble would arise owing to absorption. The saggars are "placed" or stacked in the oven. This oven is known as the "glost" oven, and the man who stacks the saggars containing the glazed ware is called a "glost placer." Before the ware reaches the "glost placer" it passes through a drying room and is cleaned. Where there are small holes in the ware, in pepper pots, for instance, any glaze filling the openings must be entirely removed.

The saggars are arranged in the oven, as in the case of biscuit ware, but this time rolls of fireclay are placed between the saggars. This clay, by the pressure of the saggar above, effectively prevents any products of combustion from reaching the glaze, which, obviously, would be spoiled.

Decorating.—In the early days of pottery making, decoration was not as we understand it to-day—it was confined more to shapes than applied colours. Those who are familiar with the Greek urns will readily appreciate the beauty of the outlines; but in the 20th century pottery is judged more by the decorative scheme. Our modern potters do, of course, pay considerable attention to shapes; but the general public, with an appetite for colour, looks for applied decoration.

The limitations, and the great skill required by the pottery artist, are little known to the average purchaser in a retail establishment. Unlike most other decorative processes, the colours, especially if under the glaze, have to be subjected to a very high temperature for the glaze itself demands this, and therefore many pigments are unsuitable, as they would be destroyed by the heat. Metallic oxides are used, such as cobalt oxide for blue, uranium oxide for yellow, chromium oxide for green, iron oxides for reds and reddish browns.

Underglaze decoration is particularly suitable for household ware, as it is indestructible, and cannot be worn off in use. On the commoner types of domestic china the design would probably be "printed," a process which is carried out as follows. A copper plate is engraved with the design, which is filled with colour mixed with oil. The printer cleans off any surplus colour and then applies a sheet of tissue paper (which has been water sized) to the plate. The copper plate, with the paper above, is then passed through a roller press, which causes the decoration to adhere to the paper. The tissue is now pressed on to the ware, and on its removal, by

soaking in water, the decoration remains behind. The design will probably be in outline and this may be filled in by hand, an operation cleverly carried out by girls. When the decoration is complete the next step is to remove the oil, for this would interfere with the application of the glaze. To do this the ware is placed in a kiln, where it is fired at a low temperature, though a sufficiently high one to destroy the oil and leave the colour "fixed." The china is now ready for the glaze, and is finished as already described. Hand-painted work can also be done under the glaze—with a limited palette.

For overglaze decoration a much wider range of colours is possible. A flux is added so that the resulting colours are really glasses, although enamels, as they are called in the industry, is a better term, which will be readily understood if one thinks of the enamelled ware in jewellers' shops—not the air-dried enamel used by house decorators.

Many pieces of domestic ware have a gold band or a gold treatment somewhere in the decoration. This is applied in two forms: "best" gold and "liquid" gold, which is an alloy. The "best" gold comes out of the kiln in a dull condition, but can be burnished to a bright tone. The "liquid" is bright when it leaves the kiln, but it has not the beauty or the wearing qualities of the other. There is a type of decoration known as "acid gold." A design is etched on to the glaze with hydrofluoric acid, which eats away the glaze unprotected by a "resist." The etched part may be coated with "best" gold, which, after being fired, is burnished, with the result that the gold in the depressions formed by the etching remains dull, while the burnished part is bright.

The decoration particularly suitable for rapid production is that of lithography. Lithographed designs are quite common for the cheaper classes of ware, and, while they may not always appeal to the critical eye, nevertheless satisfy a large percentage of the population.

The design is made up on several stones, one for each colour. These colours are transferred to sheets of paper, so that the complete decoration is obtained on one sheet. We have now what is commonly termed a "transfer." This is applied to the ware, the design remaining after the removal of the paper. The colours are fired in the enamel kiln.

A type of decoration that has not been employed to any great extent since the 19th century is that obtained by building up flowers, in clay, petal by petal, on the ware. This calls for exceptional skill on the part of the artist.

Very fine effects are obtained with a process of decoration known as "pâte-sur-pâte." Commercially various designs are modelled in white clay and affixed to the ware.

THE USES OF CHINA

Owing to its acid and heat resisting properties china finds a special use in chemical industries. It will often be found in large industrial concerns where cleanliness is of great importance. It is even employed in grinding—porcelain balls pound materials in a cylindrical machine known as a "ball mill." Porcelain is also used for the linings of these mills.

It is a splendid material for insulating, and consequently is much used by the electrical industry. In Central Europe the bowls of tobacco pipes are composed of porcelain.

Its use in domestic ware is well known, while almost everyone possesses a dainty figure or some other piece of ornamental porcelain. (*See* also POTTERY AND PORCELAIN; EARTHENWARE.)

See Emile Bourry, *A Treatise on Ceramic Industries* (trans. from the French with some additional notes by Alfred B. Searle), giving a complete description of pottery processes; *The Manual of Practical Potting* (ed. Charles F. Binns); Rudolf Hainbach, *Pottery Decorating* (English trans. published); William Burton, *Porcelain*, describing the nature, art and manufacture of porcelain; A. Malinovzsky, *Ceramics*, a book for chemists and engineers in the pottery industry; C. F. Binns, *The Potter's Craft*, for the studio potters, schools, etc.; Chas. J. Noke and H. J. Plant, *Pottery*, a small popular book by two men well known in the pottery industry; *A Text Book for Salespeople engaged in the Retail Section of the Pottery and Glass Trades*, written by an expert committee in conjunction with the Education Committee of the Pottery and Glass Trades' Benevolent Institution for the guidance of students. (G. C.)

UNITED STATES CHINAWARE

Earthenware.—The tableware made in the United States represents to a very large extent a high grade of white earthenware, also called semi-vitreous or white ware. This product is made in 60 potteries and its composition is approximately as follows: Ball clay 24%, feldspar 12, china clay or Kaolin 29, flint 35. The use of American clays has steadily replaced the imported materials. The biscuit firing is done at about 2,282° F, pyrometric cone 9, the glost firing at 2,150°, cone 5, and the decorating firing at 1,330°, cone .017. The glaze is invariably a boro-silicate of the alkalies, lime, lead and zinc. The operations are practically the same which prevail in Staffordshire (England) except that both the bisque and the glost firing are carried to a higher temperature.

The use of tunnel kilns for all three firings has become very extensive. Ivory coloured ware is produced in large quantities and this colour is obtained through the use of larger amounts of American ball clay and the introduction of yellowish firing kaolins. The tendency towards the application of vivid coloured glazes is very marked at the present time. Considerable under-glaze decoration is applied. The principal centre of the white earthenware industry is near East Liverpool, O., including potteries located just across the Ohio river, at Newell and Chester, W. Va. Within a short distance of East Liverpool factories are operating at Sebring, East Palestine, Minerva, and Carrollton, O. Formerly, a considerable quantity of white ware was produced at Trenton, N.J. But this activity has diminished to comparatively small operations.

Vitreous Ware.—The demand for non-absorbent, vitreous table ware for hotels and restaurants has stimulated the American potters to develop such a product quite obviously from the semi-vitreous type of body through the increase in fluxing material and the raising of the bisque firing temperature. Thus, the composition of a vitreous body would be as follows: Feldspar 15%, flint 38, ball clay 6, china clay or kaolin 40, whiting 1. The biscuit firing is carried to cone 11, or about 2,300° F. The resulting product shows the "stony" type of vitrification as distinguished from the "glassy" structure, possesses great toughness and mechanical strength and is translucent but markedly less so than the hard fire porcelains of continental Europe and bone china. The processes are essentially the same as practised in the earthenware manufacture except that, previous to the biscuit firing, the green flat ware is sanded, in which operation sand is shaken between the individual plates of a bung. The glaze is practically the same as that of earthenware though it is fired to a somewhat higher temperature. Under-glaze decoration is used to a large extent though largely confined to lines and plain printing. However, increased application is being made of polychrome lithographic transfer, decalcomania, as the development of the industry extends to the production of household china. Over-glaze decoration is also applied. The vitreous tableware industry is scattered and factories are located at Trenton, N.J., Syracuse, N.Y., Beaver Falls, Pa., New Castle, Pa., Wheeling and Clarksburg, W.Va., and Wellsville, O.

Belleek China.—There is produced in the United States a highly decorated grade of china, known as the Belleek type, which is named after a similar porcelain produced in Ireland. This product has attained an international reputation under the name of Lenox china. The porcelain is highly translucent, of an ivory colour and has a texture well suited for ornate decoration. The main flux of the body is a pre-fused, glassy mass, composed of feldspar, flint and alkalies. The body thus consists of this flux, feldspar, china and ball clay. The biscuit firing temperature is considerably below the maturing point of the other types of porcelain. The glaze is a very brilliant boro-silicate of the alkalies, lime, lead and zinc.

The principal production of this type of china is at Trenton, N.J.

Hard Fire China.—Hard fire china, similar to the porcelains of Austria, Czechoslovakia, France and Germany, with a low temperature biscuit and high glost fire, is produced only by two factories and on a comparatively small scale. The body employed is somewhat more silicious than the typical European product.

FIRING AND DECORATING

Top left: Dipping cups into tubs of glaze, a process to which all china for domestic purposes is subjected. This glaze after firing in a kiln makes an extremely hard and durable finish

Top right: A "sagger" in which glazed ware is being arranged for firing. The pieces are packed separately, extreme care being taken that no mark is left on the glaze

Centre left: Kiln fireman removing car of ware from firing kiln

Centre right: Applying decalcomania decoration to ware. Decal is placed over previously applied varnish and rubbed to make it adhere smoothly

Bottom left: Liner applying gold or other colours to ware in final decoration

Bottom right: Final firing in electric kiln to burn decoration into finished ware

which has approximately the composition: Kaolin, 50%, feldspar, 25% and flint, 25%. The glost firing temperature is somewhat lower than that of European practice, being close to 2,410° F., or cone 12. There are indications that a considerable expansion in the production of hard fire porcelain is to be looked for in the near future. Laboratory and technical porcelain is being produced by two factories.

The subject of high fire porcelain cannot be dismissed without referring to an American development which works with exceedingly high temperatures. Through the introduction of synthetic mixtures or of natural minerals of the sillimanite group which have the general composition, $Al_2O_3SiO_2$, aluminous porcelains are produced which show remarkable mechanical strength and resistance to thermal shock. These properties are associated with the development within the fired body, of a crystalline compound, mullite, which has the composition, $3Al_2O_32SiO_2$. This compound is formed in all porcelains but in these special bodies, through the deliberate exclusion of nearly all crystalline silica and its replacement by the aluminum silicate just referred to, a large proportion of the mass consists of mullite. The porcelains are fired at temperatures between 2,650–3,000° F., cones 17 to 30. The dense crystalline structure and low thermal expansion are responsible for the high mechanical strength and resistance to thermal shock. This type of porcelain is marketed in the form of insulators for spark plugs and other electrical purposes, laboratory and technical ware, special refractories, etc. Products of this kind are known on the market as sillimanite porcelain.

Bone china, as made in England, is produced in the U.S. only in small quantities, because of the lack of the specially skilled and trained workers required in its manufacture. (A. V. B.)

CHINCHA ISLANDS, 14 or more small islands in the Pacific ocean, about 12 mi. from the coast of Peru, to which country they belong, opposite the town of Pisco, and 106 mi. from Callao, 13° 38′ S., 76° 28′ W. The largest of the group, known as the North Island or Isla del Norte, is only four-fifths of a mile in length, and about a third in breadth. They are of granitic formation and rise from the sea in precipitous cliffs, worn into countless caves and hollows. Their highest points attain an elevation of 113 ft. The islands have yielded a few remains of the Chincha Indians. They were formerly noted for vast deposits of guano, and its export was begun by the Peruvian government in 1840. The supply, however, was exhausted in 1874. In 1853–54 the Chincha islands were the chief object in a contest known as the Guano war between President Echenique and General Castilla; and in April 1864 they were seized by the Spanish rear admiral, Pinzón, in order to bring the Peruvian government to apologize for its treatment of Spanish immigrants. The government enforces strong regulations for the protection of the sea birds, and repairs the cliffs with cement as needed to ensure the continuance of guano deposits.

CHINCH BUG, a North American heteropterous insect (*Blissus leucopterus*) occurring in most parts of the United States, but particularly destructive to grain crops in the valleys of the Mississippi, Missouri and Ohio rivers. It is a most destructive native insect, and has frequently damaged crops to the extent of many million dollars in a single year. It was first noticed in North Carolina, at the close of the Revolutionary War, was first described and named by Thomas Say in 1831, and with the growth of agriculture in the middle west, soon became a pest of the first importance. By 1871 it had damaged the wheat, oat and barley crops of several midwestern states to the estimated amount of $30,000,000. The loss in 1887 to maize, wheat and oats was estimated at $79,000,000. Federally supported and organized programs, conducted to protect crops from the insects, have been successful. In one year, for instance, it was estimated that through a combined federal and state expenditure of $1,212,776 in a co-operative effort to control the chinch bug, at least $25,500,000 worth of corn was saved from destruction.

Originally the chinch bug fed upon wild grasses, but when the cultivation of wheat reached its native haunts it multiplied enormously. It is a small black and white insect, about ⅛ in. long, and when full grown has a long-winged and a short-winged form. The adult bugs hibernate in sheltered places, usually clustering about the roots and bases of grassy plants. In the spring they lay their eggs behind the lower blades of the grain or in the ground around the plants.

The young, when hatched, are bright red in colour, and begin at once to suck the sap of the plants. They grow rather rapidly and shed their skins five times, the adult being the sixth stage. (*See* fig. 6 under HEMIPTERA.) By the time the majority are full grown, or even before, the wheat has become too hard to suck, or harvest begins, and they are then compelled to migrate in search of food. The cropping systems prevalent in the middle west at once offer new sources of food.

In seasons of abundance the bugs march in throngs from the wheat to the maize. The full-grown individuals do not generally take wing, but walk along the ground. Occasionally, however, at this time they take wing and scatter. There is generally a second generation on maize, the adults appearing in the autumn and flying back to their winter quarters at the roots of wild grasses or other sheltered places. The chinch bug is most susceptible to weather conditions, and with wet weather in the late spring and toward the end of July the young are either destroyed by the water or develop an epidemic fungous disease.

In dry weather, however, they flourish. Seasons in which they occur in great numbers are rarely consecutive. Outbreaks have lasted for two or three years, but, in the same locality, years of abundance are apt to be separated. Serious damage may be obviated by proper cropping of farms, reducing the acreage of small grains and using the land for immune crops. Resistant varieties of grains have also been found.

At the time of migration, millions may be destroyed by barriers of various kinds, including ditches, and lines of coal tar, creosote or gas tar, or creosoted paper fences.

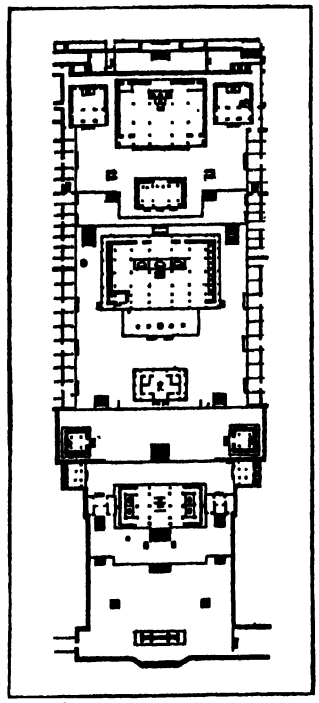
See *Farmers' Bulletin* No. 1780, U.S. dept. of agriculture; and *Iowa Extension Circular* No. 213. (L. O. H.; X.)

CHINCHILLA, a small gray hopping rodent (*Chinchilla lanigera*), the size of a squirrel, inhabiting the eastern slopes of the Andes in Chile and Bolivia, at altitudes between 8,000 and 12,000 ft. It typifies not only the genus *Chinchilla,* but the family Chinchillidae (*see* RODENTIA). The chinchilla is about 10 in. in length, exclusive of the long tail, and in the form of its head somewhat resembles a rabbit. It is covered with a dense soft fur of a delicate French gray, darkly mottled on the upper surface and dusky white beneath, the ears being long, broad and thinly covered with hair. Chinchillas live in burrows. They associate in communities, forming their burrows among loose rocks, and coming out to feed in the early morning and toward sunset. They feed on roots and grasses, and when eating they sit on their haunches, holding their food in their forepaws. The fur (*q.v.*) of this rodent was prized by the ancient Peruvians, and the skins are exported in numbers to the markets, where they are made into muffs, tippets and trimmings. That chinchillas have not under such circumstances become extinct is owing to their fecundity, the female producing five or six young twice a year. The Peruvian chinchilla (*C. brevicaudata*) is larger, with relatively shorter ears and tail; while still larger species constitute the genus *Lagidium,* ranging from the Andes to Patagonia, and distinguished by having four in place of five front toes, more pointed ears, and a somewhat different skull. (*See* also VISCACHA.)

THE CHINCHILLA, A NATIVE OF THE SOUTH AMERICAN ANDES. ITS FUR IS EXTREMELY VALUABLE AND THE SPECIES IS NEARLY EXTINCT

CHINDE, a town of Portuguese East Africa and the seat of a district in the province of Zambezia, is situated at the mouth of the Chinde branch of the Zambezi river in 18° 40′ S., 36° 30′ E. Pop. (1936) was 3,894, of which some 150 were Europeans. Chinde, having superseded Quelimane, is the chief port for the Zambezi valley and the starting point for river traffic to the interior (to Tete and Sena). The harbour, which at high water has

a depth of 18 to 19 ft., has remained undeveloped, serving primarily the lower Zambezi valley where sugar, cotton, ground-nuts and sisal are grown. A slip serves the stern-wheel river steamers which connect with the steamers visiting the port and ply up and down the river to Chindio and Tete. After the completion of the railroad from Beira to Tete and British Nyasaland in 1939, it lost much of its former importance which depended largely on the shipping to the British protectorate.



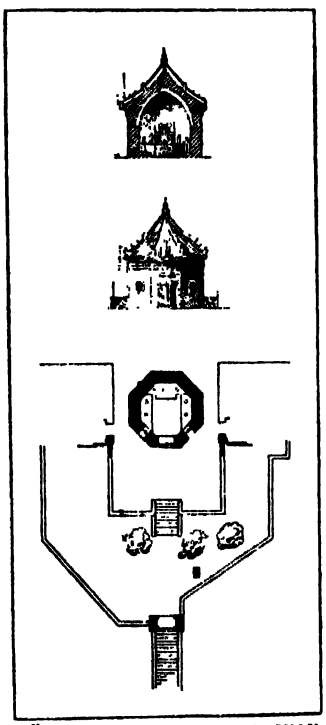
Unlike most Portuguese towns in East Africa, Chinde is a new settlement owing its origin to the discovery by D. J. Rankin in 1888 that the Chinde branch of the Zambezi was navigable from the ocean. In 1891 the British government leased a British concession of 20 ac. in order to permit storage and the entry of duty-free goods destined for Nyasaland. When, in 1923, following the opening of the Beira-Chindio in 1922, the concession ceased to exist, Chinde's commercial decline began. Previous to this the town was almost completely destroyed by a cyclone on Feb. 24, 1922, at which time more than 100 persons were killed.

The climate of Chinde is tropical and during the southern winter rather healthful; during the rainy season, which lasts from Dec. to March, it is unpleasant, particularly on account of the prevalence of malaria. Rainfall is rather heavy (about 58 in. annually), contributing to erosion, which makes the continual reconstruction of Chinde's buildings necessary. (H. A. Wf.)

CHINDWIN, river of Burma, the largest tributary of the Irrawaddy, called Ningthi by the Manipuris. It is formed by the junction of the Tanai, the Tawan and the Tarôn or Turông, but there is doubt as to which is the main stream. The Tanai rises on the Shwedaung-gyi peak of the Kumôn range, 12 m. N. of Mogaung, and flows due north until it reaches the Hukawng valley, when it turns to the west and meets the Tarôn or Turông river. The last-named flows into the Hukawng valley from the north. Its sources are in the hills to the south of Sadiya, rising from 10,000 to 11,000 ft. above sea-level. It flows in a general east to west direction as far as its junction with the Loglai. It then turns south and breaks into the Hukawng valley a few miles north of Saraw and meets the Tanai about 10 m. above Kintaw village. Below the Hukawng valley the Chindwin is interrupted at several places by falls or transverse reefs. At Haksa goods have to be transhipped from large boats to canoes. Not far below this the Uyu river comes in on the left bank at Homalin, and from this point downwards steamers ply for the greater part of the year. The Uyu flows through a well-cultivated valley, and during the rainy season it is navigable for a distance of 150 m. from its mouth by steamers of light draught. Below Kindat, the only considerable affluent of the Chindwin is the Myit-tha, which drains the Chin hills. The Chindwin rises considerably during the rains, but in March and April is so shallow in places that navigation is difficult even for small steam launches. Whirlpools, narrows and sandbanks also cause great trouble. The extreme outlets of the river are 22 m. apart, the interval forming a succession of long, low, partially populated islands. The most southerly mouth of the Chindwin is, according to tradition, an artificial channel, cut by one of the kings of Pagân. It was choked up for many centuries, until in 1824 it was opened out by an exceptional flood.

CHINDWIN, UPPER and **LOWER,** two districts in the north-west border division of Burma. Upper Chindwin has an area of 16,037 square miles. Pop. (1941), 209,575. Lower Chindwin has an area of 3,480 square miles. Pop. 427,340. For further details *see* BURMA.

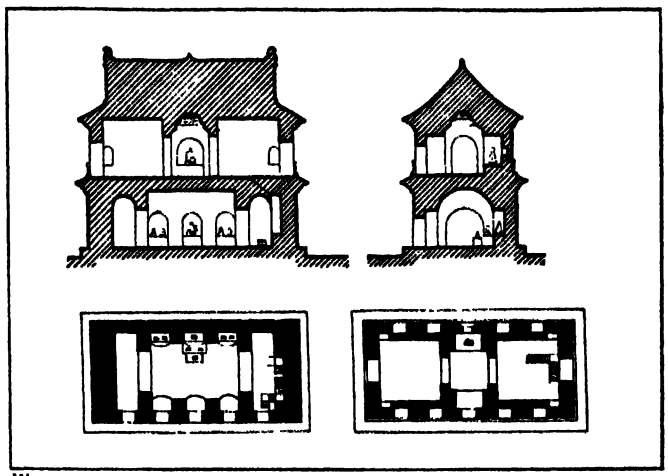
CHINESE ARCHITECTURE. The art of building in China has always been closely dependent on the intimate feeling of the Chinese people for the significance and beauty of nature. They arranged their buildings with special regard to the "spirits of earth, water and air," their ambition being not to dominate nature by their creations, as Westerners mostly do, but to co-operate with it, so as to reach a perfect harmony or order of the same kind as that which is reflected in the creations of nature. It was less the outward forms that interested them than the inner meaning, the underlying creative forces. This is most evident in the arrangement of some of the great tombs and shrines or in open-air altars dedicated to the divinities of heaven and earth. But it is also reflected in profane buildings such as the imperial palaces, which were planned and built according to sidereal or cosmological considerations. This appears even from the name used for the present and some earlier imperial palaces: Tzu Chin Ch'eng, the so-called Purple (or Violet) Forbidden City, of astronomical origin: the Heavenly Lord or Ruler Above was supposed to occupy a circumpolar constellation composed of 15 stars called the Purple Protected Enclosure, and as this was situated in the centre of the celestial world, so was the palace of the emperor, the human representative of the highest divine principle, supposed to be in the middle of the human world.



CHINESE TEMPLE PLAN
Showing the usual arrangement of placing the main buildings in a row, the one behind the other

The general arrangement and planning of the Chinese buildings have indeed very little in common with such artistic points of view as have been applied in Western architecture; they result rather from religious and philosophical ideas which have their roots in most ancient traditions. This accounts also for the uniformity, not to say monotony, of early Chinese architecture. The principles of construction have remained the same during many centuries, as have also the plans of the temples and palaces. The modifications of style which have been introduced are of comparatively small importance. It thus becomes possible to draw some conclusions from relatively late examples about the earlier buildings, which unfortunately are practically all destroyed; the wooden material has poorly withstood the ravages of fire and warfare, and the people have never made any serious efforts to protect their old buildings. It was mainly for the dead that the Chinese created more permanent abodes, and thus the tombs are the most ancient architectural monuments still existing in China. Besides these there are some cave temples hollowed out in the mountain sides and a few stone and brick pagodas of early date which will be mentioned later.

The Walls of China.—The earliest architectural monument above the soil in China is the "Great Wall," a massive fortification running along the northern and north-western frontier of the country. It was erected by the great Emperor Ch'in Shih Huang Ti shortly after he had reunited the different parts of the country into an empire (228 B.C.). No doubt minor parts of such a wall had existed before his time, but he planned his defence against the nomadic tribes on a very much larger scale than had any previous ruler. It is stated that nearly 750km. of the wall were built during his reign. Whatever truth this statement may contain, the fact remains that he laid the foundation of one of the world's grandest constructions, which, after many enlargements and restorations in the course of time, is still of great importance. The structural character of the wall is quite simple. It is built mainly of earth and stone, varies in height between 6 and 10 metres and is mostly covered by a coating of bricks. On the ridge of the wall runs a passage three or four metres wide between crenellated parapets, and at regular intervals square watchtowers rise above the ridge on which fires were lighted as soon as any danger was sighted. In spite of this uniformity, the wall is intimately connected with the landscape, rising in many parts almost like one of nature's own creations, accentuating the sharp ridges of the mountain chains and winding according to the undulations of the ground. It is the greatest and most monumental expression of the absolute faith of the Chinese in walls.

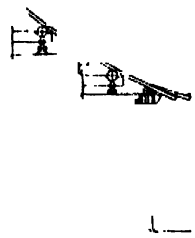


Walls, walls and yet again walls, form the framework of every Chinese city. They surround it, they divide it into lots and compounds, they mark more than any other structures the basic features of the Chinese communities. There is no real city in China without a surrounding wall, a condition which indeed is expressed by the fact that the Chinese used the same word *ch'eng* for a city and a city wall; there is no such thing as a city without a wall. It is just as inconceivable as a house without a roof. These walls belong not only to the provincial capitals or other large cities but to every community, even to small towns and villages. There is hardly a village of any age or size in northern China which has not at least a mud wall or remains of a wall around its huts and stables. No matter how poor and inconspicuous the place, however miserable the mud house, however useless the ruined temples, however dirty and ditch-like the sunken roads, the walls are still there and as a rule kept in better condition than any other building. Many a city in north-western China which has been partly demolished by wars and famine and fire and where no house is left standing and no human being lives, still retains its crenellated walls with their gates and watchtowers. These bare brick walls with bastions and towers, sometimes rising over a moat or again simply from the open level ground where the view of the far distance is unblocked by buildings, often tell more of the ancient greatness of the city than the houses or temples. Even when such city walls are not of a very early date (hardly any walls now standing are older than the Ming dynasty) they are nevertheless ancient-looking with their battered brickwork and broken battlements. Repairs and rebuildings have done little to refashion them or to change their proportions. Before the brick walls there were ramparts round a good many of the cities and towns as still may be seen at some out-of-the-way places; before the towns were built there were villages or camps of mud and straw huts surrounded by fences or ramparts of a temporary character.

YÜ HUANG MIAO ON PIAO SHAN NEAR TSINANFU

Types and Construction of Buildings.—Whether the buildings were imperial tombs, Buddhist temples or memorial shrines dedicated to great philosophers or on the other hand, of a profane nature, such as imperial palaces, dwelling-houses or administration offices, all were arranged within walls and in closed compounds according to similar principles. Characteristic of all these extensive compounds is the clear development of a main central axis running from north to south. The principal buildings, their courts and gateways are all placed in a row, one behind the other, while the secondary buildings are arranged at the sides of the courtyards, the façades, the doors and the gates of the principal buildings all facing south, an orientation which evidently was based on religious traditions. It was not by adding to the height of the buildings but by joining more courts to the compounds that these architectural compositions could be enlarged. There are princes' palaces in Peking which have as many as 20 courtyards and some of the large temples or monasteries have a still larger number of such units. As each compound is enclosed by a high wall it is quite impossible to obtain any idea of the arrangements from the outside, and at the larger palaces the different courtyards are also divided the one from the other by secondary walls with decorative gateways. The courts vary in size and the streets follow along the walls. Through such an arrangement the inner portions of the Purple Forbidden City of Peking became almost labyrinthine.

The types of the principal buildings also remain the same, independently of their use as temples, palaces or dwelling-houses. The most common among these types is the hall, *tien, i.e.*, an oblong, rectangular room, usually divided by rows of round pillars or columns into three or more naves of which the foremost is usually



WU-LIANG TIEN, SUCHOW, A 2-STOREYED HALL WITH BARREL VAULTS

arranged as an open portico; in other cases the open colonnade is continued all around the building. The interior is, as a rule, lighted by small windows placed quite low, but exceptionally there may be a second row of windows, giving a brighter effect; these are at a higher level. Very important for the decorative effect of the buildings is the broad substructure, the terrace and the far projecting roof. When the substructure is made higher, a so-called *t'ai* is created. *i.e.*, a shorter hall or a centralized building in two storeys on a high terrace with battered walls. Such *t'ai* are often mentioned in the old descriptions of palaces and cities. They seem to have been quite common since earliest times. In the Forbidden City of Peking this type of building is beautifully developed at the outer gates as, for instance Wu Men, where the great pavilion rises on a monumental terrace. Other characteristic examples of *t'ai* are the drum and bell towers which rise in the centre of many of the old cities in northern China, but similar buildings have also been used as storehouses, watchtowers and observatories. The general name for larger, many storeyed buildings is *lou*, a name which, however, is not used for the pagodas, whereas small buildings of two or more storeys often are called *ko*, and the open small pavilions *t'ing*. Furthermore, one finds in some of the palatial compounds as well as at many private dwelling-houses, particularly where they are connected with gardens, so-called *lang, i.e.*, long open galleries which serve to connect larger buildings.

Considering the most common Chinese buildings such as the *tien*, the *t'ai* and the *t'ing* in their entirety, we may be struck by the fact that the main body of the structures appears much less than in Western buildings. It is, figuratively speaking, pushed into the background by the broad terrace and the far projecting roof which throws a broad shadow over the façade. These two elements are of the greatest importance for the general effect of the structure. The terrace may be developed in various steps and provided with marble balustrades and decorative staircases, as, for instance, at the imperial palace and many large temples, or it may be simply a stone-lined substructure with one or two steps; but it always contributes to lift the building and to form a kind of counterbalance to the projecting roof. It is, however, at the *t'ai* that the substructures become of greatest importance. They may reach a height of 10 or 12 metres and be covered by a hall or pavilion of tower-like effect.

The buildings which rise on the terraces are made of wood; their structural frame is pure carpenters' work. The walls may look massive and appear to support the roof but, practically speaking, they have no structural importance. They are simply filled with brick or clay between the supporting columns. In the larger buildings the outer wall on the façades is usually not placed in the fore-

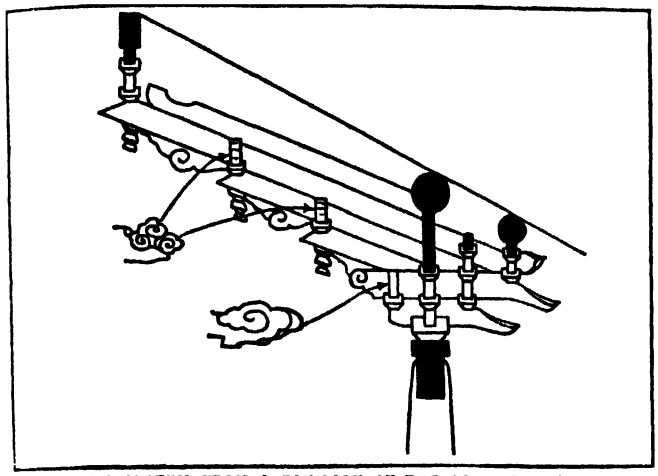
most row of columns but this is reserved as an open gallery. In some instances the portico is double, in other cases it is reduced to a few intercolumns in the middle. The building thus consists of a nave and aisles some of which might be completely or partly divided by filled-in walls, by which various rooms are created which indeed may be quite freely increased or decreased, the middle one being, as a rule, the broadest. The intervals between the columns are on the whole quite wide, and sometimes it happens that some columns are excluded in the midst of the building in order to create more free space. But the Chinese hall is not a longitudinal structure like the Greek temples (which also originally were built of wood); it expands transversally to the central axis which is indicated by the entrance door on the middle of the façade. The two short sides with the gables serve no other purpose than to end the hall; they have no decorative importance and no such emphasis as in the classic temples; sometimes they are hardly meant to be seen. The side walls may project as a kind of ante-room to the portico or the corners may be accentuated by columns. The Chinese builders were never so particular or consistent in the placing of the columns as the classical architects. They employed a material which allowed greater freedom than the marble beams and they yielded less to purely artistic considerations than to practical wants. The beauty and strength of their architecture depend mainly on the logical clearness of the constructive framework.

ROOF CONSTRUCTION ACCORDING TO YING TSAO FA SHIH (1103)

This comparative freedom in the placing of the columns is rendered possible also by the fact that they are not supporting posts as in the classical buildings. They are not provided with capitals and they do not support the entablature, but they are tied both longitudinally and transversally by beams which may cut into, or run through, the posts. The ends of the transverse beams often project in front of the columns, and the longitudinal beams form a kind of architrave which keeps the outer colonnade together. In larger buildings of comparatively late periods brackets or cantilevers are sometimes introduced on the columns below the tie beams but the real bracketing system which serves to support the eaves of the roof is situated above these. The roof brackets are, in their simplest form, two-armed and project in the earlier buildings only from the heads of the columns; but in the later buildings they become manifolded and are placed on the beams as well as on the posts, sometimes so close together that they create the impression of a cornice. It is mainly in the modifications of the bracketing system that one may trace an evolution of Chinese architecture.

The constructive system demanded that the buildings should be developed horizontally rather than vertically. Nevertheless, many of the large halls are erected in two storeys, though the second is often nothing more than a decorative superstructure without floor or windows. The lower storey forms a kind of outer compartment to the building and is covered by a lean-to shed roof while the main span or saddle roof covers the central portion of the building which rises to a greater height. Sometimes there is a coffered or painted ceiling over this portion but more often, particularly in the temples, the trusses and beams of the roof construction are left entirely uncovered.

Roofs.—It is evident that the development of the roof on the Chinese buildings is closely connected with the placing of the entrance door. This is not to be found on the short (gable) ends of the building but in the middle of the southern façade, which usually has also a free-standing row of columns. Most of the important buildings are indeed placed so that they can be appreciated only in full-front view, and their peculiar decorative effect thus becomes dominated by the broad high-towering roof. Whatever the original reason for this particular kind of roof may have been, it was gradually more and more developed from a decorative point of view. The builders may have felt the need of modifying the impression of weight and breadth, inevitably adhering to the enormous roof masses, and this was most successfully done by curving the sides and accentuating the tension and rhythm of the rising lines. This tendency becomes perhaps more evident in minor decorative buildings such as pavilions and pagodas, not to speak of small ornamental works in clay and metal on which the roof appears almost as a crown. The common dwelling-houses in northern China have, on the contrary, much smaller and less curving roofs and, if we may judge from reproductions of earlier buildings, such as the reliefs from the Han tombs in Shantung and some small clay models dating from the Han and Wei dynasties, it seems that the curved roof was then not very far developed. In the T'ang time (7th to 9th century) the characteristic shape of the roof was, however, fully developed.



It is possible that the origin of the far projecting and strongly curved roof may be looked for in primitive thatch-covered huts of a kind similar to those which still are to be seen on the Indo-Chinese islands. If so, it would first have been introduced in southern China (where indeed the curving and projecting roof always was more strongly developed than in the north), and later on, when the whole country became more of a cultural unit, in the northern provinces. When the Chinese once had realized the fine decorative effect of these roofs, they developed them freely at the expense of the main body of the building. The larger the roofs, the stronger becomes the effect of shade under the eaves and the more they seem to be disengaged from the supporting framework and to soar in the air. In many instances the roofs crown the building rather than cover it, and their decorative ornamentation with figures and animals on the ridges and on the corner ribs serve also to strengthen the impression of a decorative superstructure.

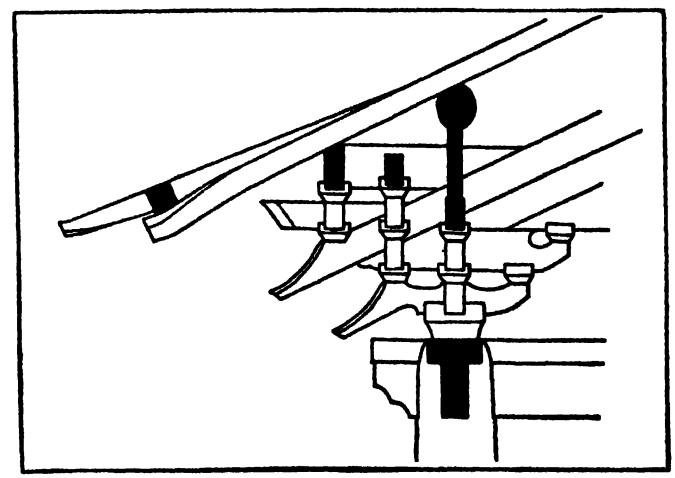
When the building has a roof in two storeys the lower one is a lean-to shed roof; the upper one, a span-roof—but the gables of this do not reach down to the eaves: they are cut at one-half or three-fourths of their height. This peculiar combination of the gabled and the hipped-roof is very common both in China and in Japan, but there are also buildings with complete hip-roofs sloping to all four sides. This is, according to the Chinese, the finest form. It is to be found on ceremonial edifices such as the big central hall Tai Ho Tien in the Forbidden City, Peking, and some of the sacrificial halls at the imperial tombs.

Buildings consisting of two superimposed halls have been in use since very early days, as may be seen on some reliefs of the Han dynasty, and they are also mentioned in many of the old descriptions of the imperial palaces, where such buildings sometimes were connected by flying bridges. Very characteristic and well-developed examples of this type of structure are still to be seen at Yung Ho Kung (the Yellow Temple) in Peking, which was erected in the 17th century as an imperial residence but afterwards consecrated as a Llama temple. Later Llamaistic buildings (from the Ch'ien Lung era) show at times an even further development in height, as for instance the Yu Hua Ko, a temple standing at the north-western corner of the Forbidden City. In southern China the distribution of storeys seems to have been still freer; there are large temples in Suchow with three superimposed halls and other more centralized structures built in the same way, which indeed may be called towers, particularly if they are placed on terraces. The constructive framework of the main roof consists generally of various beams arranged step-wise one above the other and supporting on their ends the purlins (*q.v.*). In smaller buildings all the transversal beams may be supported by columns which increase in length towards the middle of the room, the central one reaching up to the main ridge. It is, however, more common that only the lowest or the two lower beams rest directly on pillars, while the upper ones are carried by brackets and small posts rising from the lower beams. The purlins laid on these supports are arranged rather closely, so that the rafters may be stretched in curves, the projecting ones being spliced and bent upwards. The well-developed system of brackets and cantilevers which support this projecting part of the roof will be specially discussed later because it is in this that one may follow the development and decay of Chinese archi-

tecture.

The outer aspect of the roof is determined by the alternatively convex and concave tiles and the strongly accentuated corner ridges which curve at the ends in a kind of snout and often are provided with series of fantastic human and animal figures, called *k'uei lung tzŭ*. The main ridge-post is very high and decorated at both ends with a kind of fish-tailed owl, called *ch'ih wen*, which

BRACKETING SYSTEM FROM A PAVILION AT THE CONFUCIUS TEMPLE IN CHÜFÜ. YÜAN PERIOD



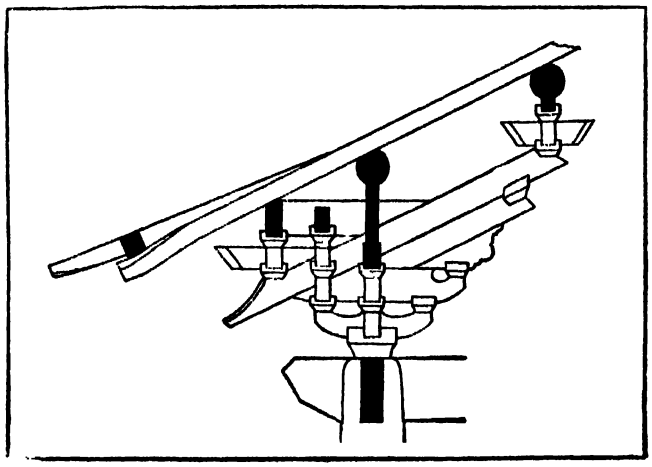
had a symbolic significance and served to protect the building against fire and other calamities. On ordinary buildings the roof tiles are of unglazed, lightly baked grey clay, but on the present imperial buildings all the roofs are laid with yellow glazed tiles, while some of the temples and smaller buildings erected for various members of the imperial family have deep-blue roof tiles. Green tiles are sometimes used on pavilions, gates and walls.

The columns as well as the filled-in walls between them have usually a warm vermilion tone which becomes most beautiful when softened by dampness and dust. The beams and the brackets below the eaves are painted with conventionalized flower ornaments in blue and green, sometimes with white contours. The door panels of more important buildings are provided with ornaments in gold, but their upper part serves as windows and is fitted only with open lattice-work. On the whole it seems as if later times had tried to gain by decorative elaboration whatever of constructive significance and beauty had been lost.

Minor Pavilions and Gateways.—Besides the longitudinal halls in right angle to the central axis, indicated by the entrance door, there are more centralized structures on a quadrangular, polygonal or round plan, *i.e.*, pavilions or towers, which may be more than two storeys high. The most primitive type of pavilion is a square hut with corner posts which carry a flat or tent-shaped roof. Such pavilions are often seen in pictures representing famous philosophers meditating on nature. Unless they are quite open the walls may be made of bamboo or basket-work. The more elaborate pavilions on a polygonal or round plan developed in connection with the Chinese garden and have been abundantly used in the imperial parks since early times. Such kiosks, tea-houses and pavilions were placed on spots with historical associations or on hills or promontories where the view was particularly beautiful. Their shape and style were developed with a view to the rockeries and the growing trees; how well they fitted into such surroundings may still be seen in the wonderful gardens around the sea palaces in Peking. These small pavilions, half hidden between the trees, clinging on the rocks or rising on stones out of the mirroring water, often give us a more vivid and immediate impression of the charm and naturalness of Chinese architecture than the larger buildings. It was also pre-eminently through such small decorative structures that Chinese architecture became known and appreciated in the 18th century in Europe.

On the larger pavilions the roofs are usually divided into two or three storeys, thus adding greatly to the picturesque effect of the building, particularly when it is erected on a polygonal plan which gives it a number of projecting corner snouts. Beautiful examples of this kind of pavilion may be seen at the "Coal Hill" in Peking as well as in Pei Hai and other imperial parks. They have no walls, simply open colonnades supporting the roof which may give the impression of hovering in the air. When the portions between the successive roofs are enlarged and provided with balconies or colonnades the pavilion becomes a real tower, such as for instance the Fo Hsiang Ko (Buddha's Perfume Tower), which rises above the lake at the Summer palace.

Related to the pavilions by their open decorative effect, yet forming an architectural group of their own, are the *p'ai lou, i.e.*, free-standing gateways with three or more openings, which span the streets in many Chinese cities or mark the entrance to some sacred precincts, such as tomb or temple areas. The object of their erection was often to commemorate some outstanding local character or some important event in the history of the place or simply to mark a spot notable for its beauty or its sacredness. The earliest *p'ai lou* were, no doubt, simply large gateways made of wood and provided with inscribed tablets. These could easily be developed into more important structures by adding at the sides more posts and gateways, and they were soon executed in stone as well as in wood. From an architectural point of view they may be divided into two principal groups: the one consisting of *p'ai lou* with very tall side posts reaching above the transversal beams (which may be covered by small roofs); the other, of *p'ai lou* with shorter side posts covered by the roofs, so that the whole gateway has more likeness to a façade or an open flat pavilion. The supporting masts, which may be 4 or 8 or 12 according to the size and importance of the structure, are placed on stone plinths, sometimes decorated with lions, and tied together not only by cross-beams in two or three horizontal rows, but also by carved or painted panels or, in the case of stone *p'ai lou*, by flat slabs decorated with reliefs. Over each one of the openings is a separate small span-roof resting on brackets and usually covered with glazed pan-tiles. The *p'ai lou* thus contain some of the most characteristic features of traditional Chinese architecture, viz., the supporting posts, the curving saddle-roofs on double or triple rows of brackets, and the carved or painted friezes. They are essentially wooden structures. The whole character of these buildings as well as their decoration has been developed with a view to the special requirements of the material, but that has not prevented the Chinese from



BRACKETING SYSTEM ON BELL-TOWER AT SHAO LIN SSU. YÜAN PERIOD

executing the same type of structure also in brick and in stone. The largest among them stand at the Ming tombs near Nankow and at the tombs of the Ch'ing emperors at Hsi Ling and Tung Ling, but the most elaborately decorated marble *p'ai lou* may be seen in some of the old cities in Shantung, such as Chüfu and Weihsien.

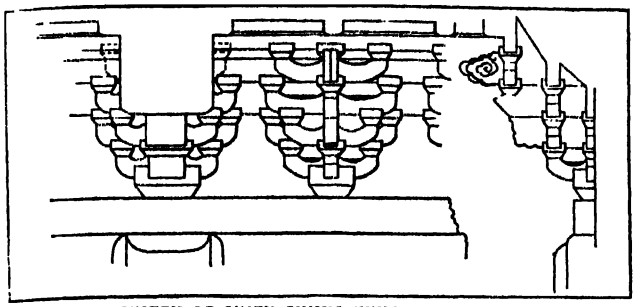
Closely connected with the *p'ai lou* are those highly decorative sham façades which used to be erected in front of important shops. They also consist of tall masts tied by cross-beams with manifold rows of brackets which support small roofs in one or two storeys.

Under these are panels decorated with human figures in relief or with brightly coloured floral designs in open-work into which the signboards of the shops are inserted. High masts or pillars are indeed much in favour in China; they are mostly used pair-wise, either free-standing in front of palaces (as the *hua piao*) or at the gateways of the dwelling compounds. Another type of gateway which is quite common consists of broad pillars made of masonry

BRACKETING SYSTEM FROM THE CH'U TZU AN, SHAO LIN SSU. SUNG STYLE

and coated with glazed tiles, often with ornaments in various colours. When a span-roof connects the deep pillars a kind of small gatehouse may be created.

Of considerable importance also for the outward effect of the Chinese buildings are the balustrades which line the terraces and staircases in front of the buildings. They are in northern China mostly made of white marble and composed of square posts ending in sculptured finials between which ornamented panels and moulded railings are inserted. Such marble balustrades may be seen at most of the important temples and, in their richest development, on the terraces of the Three Great Halls (San Ta T'ien) in the Forbidden City in Peking. Here they are repeated in three different tiers and broken in many angles, according to the shape of the terraces, producing a splendid decorative effect, particularly as the white marble stands out in contrast to the red colour of the buildings.



Stone and Brick Buildings.—Although Chinese architecture is principally wood construction, it should not be forgotten that a great number of stone and brick buildings have been made in China, including bridges, for which the Chinese since earliest times have used brick and stone. The great majority of the still existing buildings in masonry are of comparatively late periods; very few indeed can be dated before the Wan Li era (1573–1619). The only important exceptions to this general rule are the pagodas made of brick and mud, several of which may be ascribed to the T'ang period (618–907) and a few to even earlier times. On the whole, it seems, however, that the Chinese regarded brick and stone work as material fitted for storehouses, walls, substructures and the like, but hardly for real architecture in the same sense as wood construction. It is a characteristic fact that brick buildings are not even mentioned in the standard work on architecture which was published by imperial order in the year 1103 under the title *Ying Tsao Fa Shih* (The Method of Architecture). This beautifully illustrated work in eight volumes (which has been issued in a modern reprint) is founded on the practical experience of architects and decorators, which the author, Li Chieh, collected from various sources. It gives everything that an educated Chinese towards the end of the Sung period considered the fundamentals of architecture. No stone or brick houses are mentioned, not even columns, door-frames or floors of stone. The only stoneworks particularly described are the plinths and corner pilasters, stairs, balustrades, dragon heads on staircases, thresholds and stones for the door-posts, besides canals, sluices, platforms, terraces, etc. The measures and instructions for the execution of all these various kinds of stonework are very accurate, but they are of no great importance for the architectural style. The constructive methods are treated only in the third part of the book, which contains "Rules for large work in wood," *i.e.*, framework of buildings, posts, trusses, rafters, etc. Then follows a chapter called "Rules for smaller works in wood," *i.e.*, doors, windows, partition walls, coffered ceilings, screens, cornices, gutters, staircases, door-panels, balustrades, besides Buddhist and Taoist house shrines, or *Fa yüeh*, decorative gate-façades erected in front of important houses, etc. Then follow "Rules for works in carved wood," concerning decorative details, and at the end of the book, "Rules for exterior roofing," also concerning the ornamental figures on the roofs, etc. The author devotes some paragraphs to bricks and to roof tiles but he gives no rules for construction in such materials.

Turning to the existing monuments in China, we may notice the Ssu Men Ta, at the temple Shen Tung Ssu in Shantung, as the earliest and most important example of architectural masonry work. The building, which in spite of its name—the Four-Gate pagoda—is no tower but a one-storeyed square house (each side about 7·35 metres), was erected A.D. 534. It is coated with finely cut and fluted limestone slabs, but the interior body of the walls may be partly of mud. It has an arched entrance on each side and a cornice consisting of five corbelled tiers but no other architectural divisions. The pyramidal roof is made of corbelled stone slabs, and supported by a large square centre pillar crowned by a small stūpa. The solid and self-contained aspect of the building together with its fine proportions make it one of the most remarkable of Chinese architectural monuments. It is possible that similar buildings existed in earlier times when stone and brick may have been more freely used; the type may be observed, for instance, in the more or less house-shaped tomb pillars of the Han dynasty in Szechuan and Honan.

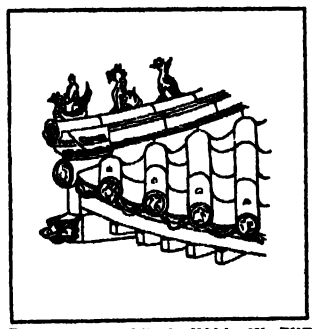
The next in date among the masonry buildings are some real towers or pagodas of the Sui and T'ang periods which will be mentioned later; most of them are made of packed clay or dirt in combination with stone or brick. Still more common is the combination of brick and wood construction. It can be carried out in different ways, either by lining a real wooden structure with brick walls or by placing a bracketed span-roof on strong brick walls, eventually adding pillars for interior support if the walls are too wide apart. This method of construction has been used in most of the outer city gate-towers, of which the oldest now preserved are from the beginning of the Ming period, and also in numerous watchtowers and storehouses on the walls that enclose the cities of northern China. A particularly fine example is the famous bell tower at Peking, often considered as a monument of the Yuan dynasty, though it was completely renewed during the reign of Chi'en Lung. All these buildings exhibit on the outside massive brick walls more or less regularly divided by windows or by rows of square loopholes which give to the battered façades of the big gate-towers a fortress-like appearance. The shape of the high roofs is, however, the same as on ordinary wooden structures, and if one examines these masonry buildings more closely, one usually finds wooden columns inserted in the walls as well as detached in the interiors.

The substructures of the gate and bell towers are in most cases pierced by tunnels or barrel vaults serving as passages. These may be either round or somewhat pointed, as for instance on the drum tower in Peking which actually dates from the Yuan period. The vaults are constructed with great care and precision, sometimes reaching a span of nearly 15 metres. Vaulting (but not the system of voussoirs) was undoubtedly known in China in early times; it was used in the tomb chambers which were covered with bricks, in the tunnels leading to these; when heavy brick walls were erected around the cities, barrel vaults followed suit for the entrances. The step from such constructions in brick to the building of cupolas is not a very long one. We do not know exactly when cupolas first came into use, but we have reason to assume that they were well developed in the T'ang period. As an evidence of this the mosque in Hangchow may be mentioned because the farthest rooms of this building are covered by three cupolas on pendentives (*q.v.*). The mosque may have been renewed in later times but in close adherence to the original model which, of course,

was of Persian origin. Another kind of cupola is to be found over the hall of the big bronze elephant on the Omi mountain in Szechuan erected during the reign of Wan Li (1573–1619). The transition of the square room into a round cupola is here also accomplished by means of pendentives but outwardly the building is covered by a tent-shaped roof. One of the small sanctuaries on Piao shan near Tsinanfu is an example of a more pointed cupola.

BRACKETING SYSTEM OF CHIEN CH'ING KUNG, FORBIDDEN CITY, PEKING

At the end of the Ming period buildings with classical orders in one or two storeys began to appear. Internally these were covered by longitudinal or transversal barrel vaults, but outwardly they were provided with the usual span and shed-roofs. Among the best examples of this kind of building may be mentioned the Wu Liang Tien in Suchow and Shuan Ta Ssu in Taiyuanfu, besides the two halls on Wu Tai Shan. The façades are divided by arches and columns, but these are partly inserted in the wall and the capitals are stunted or turned into cantilevers, the entablature reduced to an architrave, the cornice replaced by rows of brackets above which the upturned eaves project in the usual manner. This combination of classical orders and Chinese brackets is indeed characteristic evidence of how foreign the principles of Greek architecture always remained to the Chinese. Such buildings may have been inspired by Indian models, but the Chinese modified them quite freely by grafting on the pseudo-classical models elements inherited from their indigenous wooden architecture.



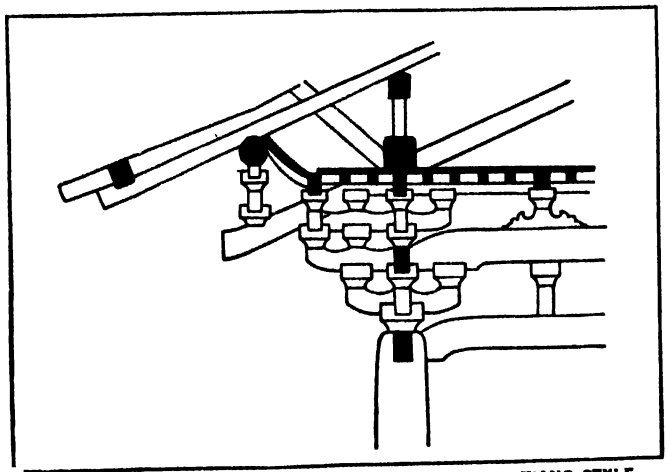
An entirely different type of masonry work is illustrated by the buildings made after Tibetan models mostly as late as in Ch'ien Lung's reign. The towers and sham fortresses on the slopes of the Western hills in Peking, which were erected in order to give the Chinese soldiers an opportunity to practise assaults, are well known by all tourists. Still larger and more important Tibetan buildings may be seen at Jehol, the famous summer resort of the Manchu emperors in northern Chihli, where an entire Llama cloister was erected after the model of the famous Potala in Lassa, the residence of the Tibetan pope-kings. This enormous brick façade in some nine or ten storeys must in its absolute bareness have appeared quite dreary to the Chinese. They have tried to give it some life or colour by surrounding the windows with pilasters and canopies made of glazed tiles, but the sombre and solid character still dominates, giving evidence of a foreign culture transplanted into Chinese surroundings.

Historical Development.—Buddhist temples and pagodas have existed in China since the end of the Han dynasty, and though the earliest ones are no longer preserved, we may obtain some idea about them from old reproductions and contemporary Japanese buildings made after Chinese models. The first messages of the new religion were brought to the Chinese at the beginning of our era, but it was not until the 2nd century A.D. that it became more widely spread, largely due to the pilgrims who journeyed between China and India. They brought news not only of the writings and images of the new religion but also of its buildings. It has been reported that small bronze models of the famous stūpa of Kanishka at Peshawar (erected in the 1st century A.D.) were brought to China by Hui Sheng, a monk who took part in a mission to India in the year 518. No doubt, other pilgrims did the same, and there may have been many small models of this much admired religious monument in China. As far as one may judge by later Indian reproductions, reverting more or less directly to the famous pagoda of Kanishka, it was built on a square platform, but the main section of it seems to have been round or bottle-shaped and divided by projecting cornices into three or more storeys. Very characteristic of this pagoda was the high mast with its nine superposed metal disks and crowning lotus bud. At present there are no such pagodas preserved in China, but ancient engravings on stone give us reason to believe that they have existed.

The oldest pagoda in China still standing is at Sung Yüeh Ssu, a temple on the sacred mountain Sung Shan in Honan. According to historical records, it was built about 523, when the palace previously existing here was consecrated as a temple. The tower is made of mud and brick on an octagonal base and reaches a height of nearly 30 metres. The lowest section consists of a plain plinth above which follows a main storey divided by pilasters and windows in a kind of aedicula (*q.v.*). The upper section of the tower has the shape of a convex cone, divided by narrow cornices into 15 low, blind storeys. It is crowned by a large bud or cone with nine rings, an equivalent to the mast with the metal disks which is usually found in the wooden pagodas. The early date of the building is verified by the style of the lion reliefs and the mouldings of the main storey.

The character of the whole structure is solid and severe, at the same time the incurvation of the outline prevents any impression of rigidity.

There is no other pagoda of as early date but the type returns with some modifications in some later pagodas, as for instance, the Pei T'a (the North tower) and the Nan T'a (the South tower) at Fang Shan in Chihli. The former, which was built at the beginning of the 8th century, shows a more typically Indian style with its bottle-shaped top, part being on a terraced substructure while the latter, which was built at the beginning of the 12th century, has a stiffer appearance without any incurvation of the outline or narrowing towards the top. It is divided by bracketed cornices into 11 storeys and reveals by its form and details a closer connection with traditional Chinese constructions. To the same group of buildings belong also the pagodas at Chêngtingfu, Mu T'a (T'ien Ning Ssu) built about 1078 in nine storeys with wooden cornices, and the Ching T'a built at a somewhat later period, and furthermore the two big pagodas near Peking, known as Pa Li Chuan and T'ien Ning Ssu, which were erected during the Chin and Yüan dynasties (in the 12th and 13th centuries). They show some likeness to the Nan T'a at Fang Shan, but their dimensions are much larger and their high plinths are richly decorated with figure reliefs in baked clay. Both have 13 low blind storeys and make quite an imposing effect by their great height, but they lack the elastic incurvation which gives to the pagoda at Sung Yüeh Ssu such an harmonious character.

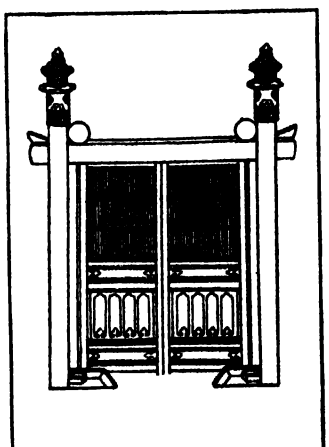


ROOF TILES ON A HALL IN THE FORBIDDEN CITY, PEKING

Many of the early pagodas in China were, no doubt, constructed of wood and have perished, because of the unresisting material. There are records of a very large wooden pagoda erected in A.D. 516 at Lo-yang at the order of the Empress Dowager Hu. According to Chinese chronicles this was 1,000ft. high (a statement which must not be taken literally but merely as a general indication of unusual height) and consisted of nine storeys. Above the tower rose a mast 100ft. high carrying 30 gilt metal discs which, as well as the chains by which the mast was tied to the four corners, were hung with no less than 500 gilt bells. This noble edifice became, however, the prey of fire in 534. The description must have been based on hearsay, but it nevertheless has some interest as testimony of the existence of wooden pagodas in China at an early date. It is also confirmed by several reproductions of pagodas found among the cave sculptures from the beginning of the 6th century at Yun Kang and Lung Men. Here one may see executed in relief pagodas with

three as well as with five storeys illustrating exactly the same architectural type as found in the earliest Japanese pagodas from the beginning of the following century. They are built on a square plan with corner posts and projecting roofs over the successive storeys and crowned by high masts carrying discs and ending in the form of large buds or small stūpas. In the successive storeys on some of these pagodas are placed Buddhist statues.

Excellent examples of the same type of pagoda may be seen at some of the old temples near Nara in Japan, as, for instance,



BRACKETING SYSTEM ON THE KONDO OF TOSHODAIJI. T'ANG STYLE

Horyuji and Hokkiji which were erected at the beginning of the 7th century in the Suiko period by builders from Korea or China. The pagoda at Hokkiji has five storeys; the bracketed roofs project quite far but narrow gradually towards the top so that the appearance of heaviness is avoided. Each side has four carrying posts with projecting cantilevers, which at the corners are placed diagonally and cut into the shape of clouds, a motif which is particularly characteristic of this period. The rafters are square and rather substantial; the far projection of the eaves is produced by a very clever construction which no doubt was developed in China before it was introduced in Japan, although the earliest Chinese examples no longer exist. The principle of this system consists in the redoubling of the rafters below the eaves: instead of placing the outermost purlins directly on the cantilevers, which project from the posts, supporting shorter rafters are introduced which are fastened in the beams and trusses of the roof and which carry by means of vertical struts or cushions the further projecting upper rafters. These may be made longer and the roof is lifted higher, the effect becoming lighter than in buildings where the purlins rest directly on cantilevers or beams. This constructive system with redoubled rafters remained in use until the Yüan period, perhaps even later, though the form of the lower rafters as well as other details becomes modified. Furthermore one may notice in these early buildings the very solid and broad shape of the various members, as, for instance, the comparatively short columns with entasis (*q.v.*) and the very broad and heavy cantilevers cut into the shape of clouds at their lower side. The trusses and beams of the roof, to which the rafters are tied, are solid and strong, the various parts being tied together with consummate skill.

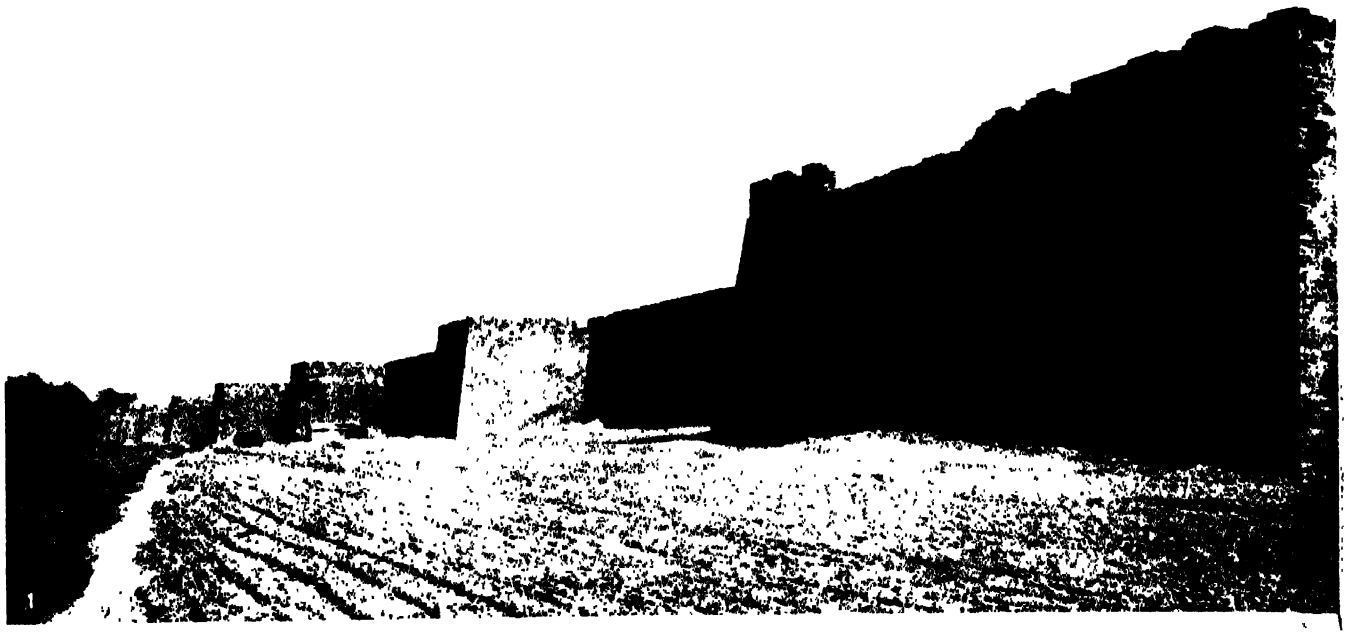
The essential parts of the buildings and the method of construction are the same in the pagodas and in the temple halls of this period, as may be learned from a closer study of the Golden Hall or Kondo of Horyuji, an oblong, quadrangular room with a colonnade and a roof in two storeys. A very important member added to the pagodas is, however, the mast which runs through the whole height of the tower. The purpose of this mast is not really constructive, it is not meant to support the tower, but simply to form a spire rising high above the roof and carrying the nine metal rings or discs. The builders usually did not tie the mast very tightly to the framework of the tower, because if the whole structure were suspended on the mast, the security of the tower would be jeopardized by the unavoidable swaying of the mast. In some comparatively recent examples one may find the mast suspended in the beams of the tower, but here the intention evidently was to lift it a little above the ground in order to avoid the still greater danger that might arise through the gradual sinking of the tower which would then, so to speak, be carried by the mast or hang on it. In the oldest pagodas which for the longest time have withstood storms and earthquakes the mast is a relatively free-standing post within the structure, always with plenty of room for its swayings, which thus do not really affect the security of the tower.

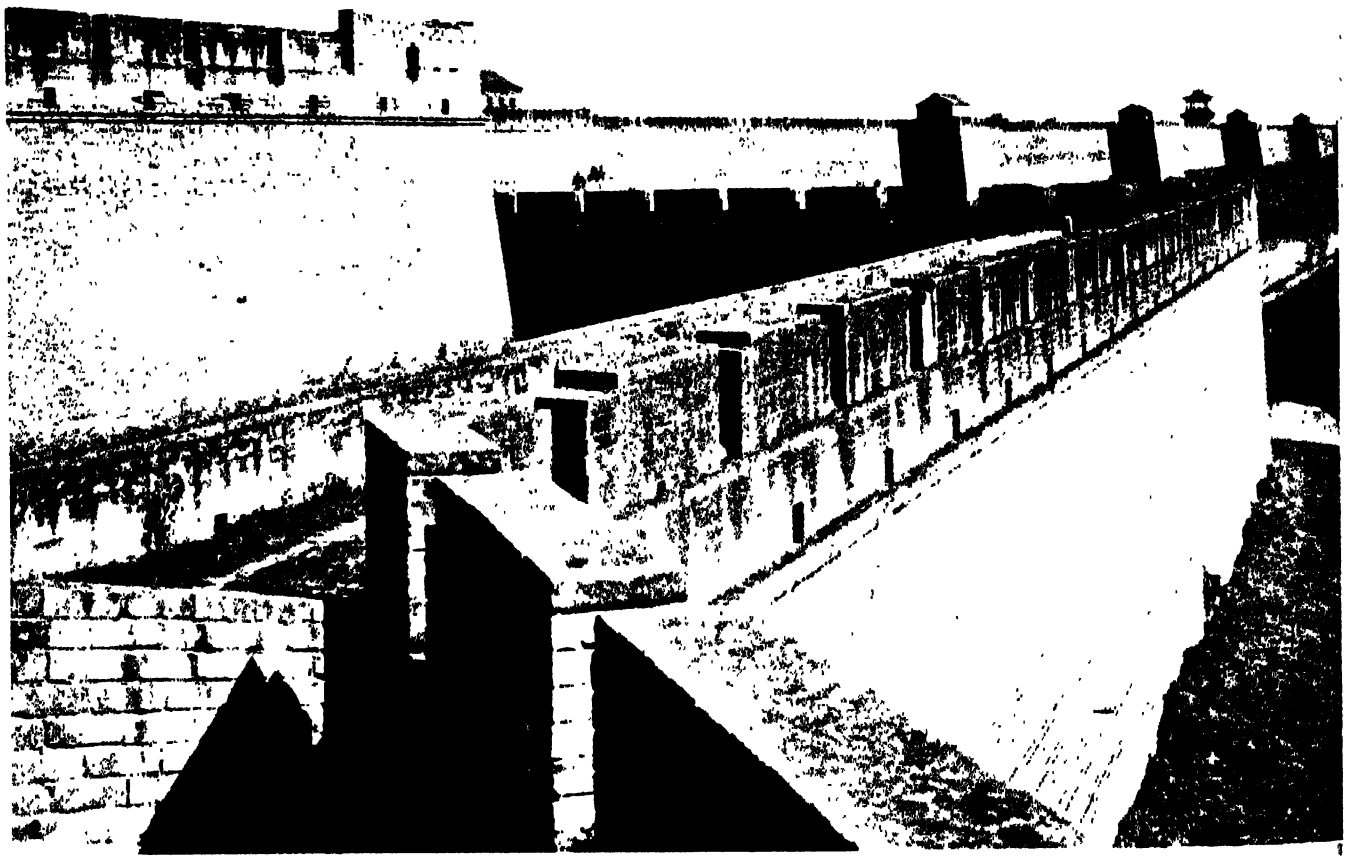
Quite a number of pagodas and temple halls of the 7th and 8th centuries are to be found in Japan, but it is our purpose here simply to point out certain general principles of construction borrowed from China. The five-storeyed pagoda at Horyuji is, in spite of the verandah which was added later round the ground storey, the most important example, but characteristic of the same style (which was developed in China, during the northern Wei dynasty and in Japan during the Suiko dynasty) are also the three-storeyed pagodas at Hokkiji and Horinji, which remind us of the stone reliefs representing pagodas in the grottoes at Lung Men and Yun Kang.

Inportant modifications of the old style may be observed on the beautiful pagoda of Yakushiji which was erected at the beginning of the 8th century in close adherence to Chinese constructions from the beginning of the T'ang period. It is a three-storeyed tower, but each one of the storeys is provided with a closed balcony carried on cantilevers, so that the pagoda at first sight gives the impression of a six-storeyed building. The intermediate shed-roofs are of the same shape, though smaller than those which cover the main storeys; a kind of rhythmic division is thus created, and the decorative effect becomes more interesting than in the earlier pagodas. Of great importance for the horizontal articulation are also the far-projecting carrying beams of the balconies, as well as the repetition of the three-armed brackets in double tiers under the eaves of the six successive roofs. The bracketing system has here attained its highest development, the lower brackets being used as supports for the upper ones which reach farther out and are provided with cushions. Their transversal arms replace the formerly used cantilevers, and on the top of them may be one more tier of similarly shaped brackets, as on other buildings of the same period. It should be observed that all the brackets are complete, the lower ones being so arranged that they carry a continuous beam and also the transversal arms of the upper brackets, while these serve as supports for the upper beams under the eaves and for the rafters. In order to strengthen the vertical construction, struts with cushions are often placed on the hammer-beams in the intervals between the brackets.

OUTER GATEWAY ACCORDING TO YING TSAO FA SHIH (1103)

The same characteristic forms and constructive features return in some contemporary temples and pagodas which thus also testify that the parts to which we have paid special attention are typical features of the architecture of this period. Interesting in this connection are the two large temple halls at Toshodaiji, another temple not far from Nara, *i.e.*, the Kodo (Hall of Teaching) and the Kondo (the Golden Hall). The former once formed a part of the imperial palace at Nara but was moved to its present place when the temple was erected in 759. The building is quite simple, an oblong, one-storeyed hall with double rows of columns all around, the inner row standing free in the room, the outer being filled out to form a wall. The columns are not quite as heavy as on the buildings of the preceding period and the inter-columns are very long. The brackets are introduced only in one tier but between them are struts which contribute to support the roof.





THE GREAT WALL OF CHINA

The Great Wall of China at the Nank'ou pass, Chih-li; 226 B.C. It is 1,400 miles long, with square watch-towers at intervals

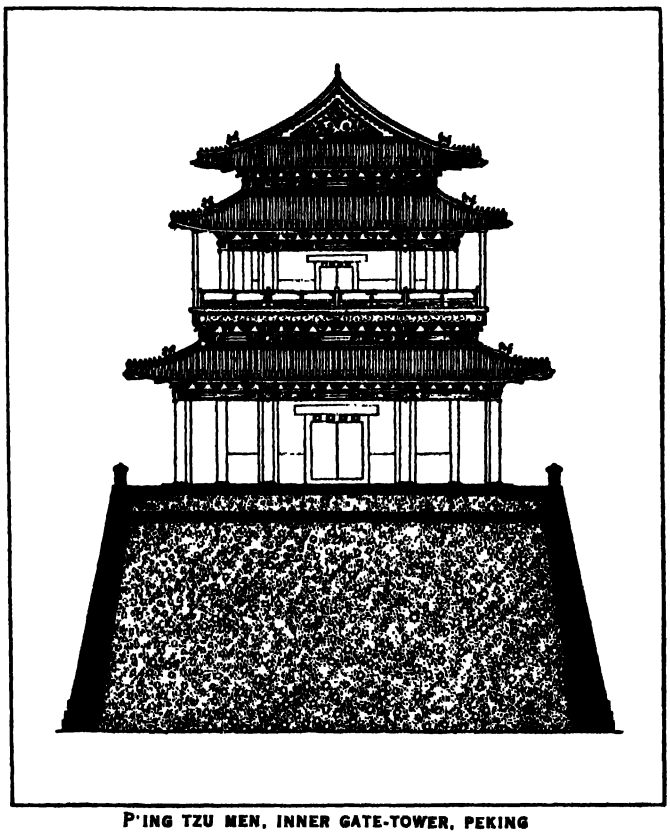
CHINESE MEMORIAL GATEWAYS

1. P'ai-lou or memorial gateway built of wood, at the lake of the Summer Palace, Peking. These characteristic structures, usually of wood, mark the entrance to a sacred or beautiful spot or commemorate some event or person
2. Marble P'ai-lou at the Altar of Heaven, Peking. This illustrates the type of p'ai-lous with tall side-posts reaching above the transverse beams
3. Marble P'ai-lou over the main street in Wei-hsien, Shantung. In this type of p'ai-lous, the shorter side-posts are covered by roofs, making the gateway resemble an open pavilion. This is one of the more elaborate examples, with three openings and storeyed roofs



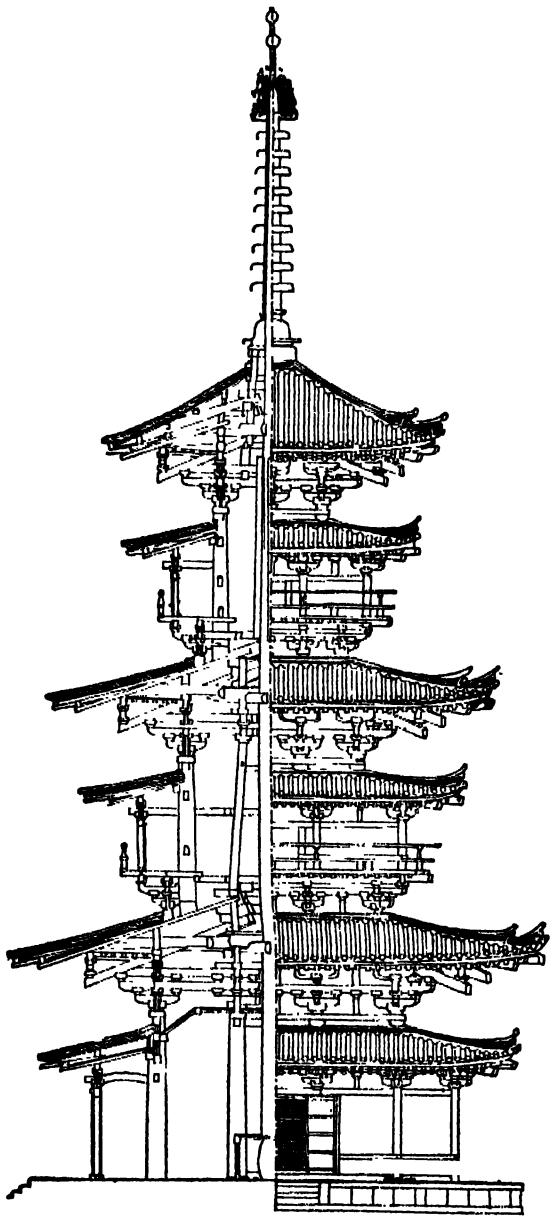
The same principles of construction are still further developed on the Kondo of Toshodaiji which, with the exception of its entirely rebuilt roof, is an unusually imposing example of T'ang architecture. The building stands on a comparatively broad and high platform, but it is provided with a colonnade only on the front. The columns have a slight entasis and rest on moulded plinths. They are tied together, as usual, by a long architrave-beam and provided with quadrangular cushions from which the three-armed brackets project. These carry the upper longitudinal beam and a second tier of brackets. Above this follows a third row of brackets which is almost hidden below the far projecting eaves. The rafters project between the arms of the uppermost brackets and abut against the tranversal arms of the second row of brackets. The rafters are doubled, the upper ones being supported by struts which also carry the outermost purlins, and the two layers are furthermore tied by braces. The whole system is carried out with perfect logic in a method which may be termed the highest perfection of wooden construction.

How closely this building depends on Chinese models is proved by the reproduction of a similar temple hall on a large stone gable above one of the gateways to the Ta Yen T'a pagoda at Sianfu. This remarkable engraving which we reproduce from a copy executed by a Japanese artist for Prof. Sekino, is of great historical importance, because it evidently reproduces a Chinese temple on which we may observe the same constructive details as pointed out in the Kondo of Toshodaiji. It matters little that the columns have been made spiky and the roof too small, as long as we recognize the principle of the whole constructive system, *i.e.*, the brackets and the struts, of which the lower ones have the same kind of curving legs as may be seen on some Japanese buildings of the 9th and 10th centuries.

Before following the further development of the traditional wooden construction during the Sung and the Yüan dynasties it is necessary to mention a group of buildings which illustrates another side of T'ang architecture. These are pagodas in what is popularly called the "Indian style," that is to say, buildings made of packed mud and brickwork which rise in terraces on a square plan. The most important among these pagodas stand in the neighbourhood of Sianfu within or just outside the district which alone was occupied by Ch'angan, the capital of the T'ang emperors. In the first place should be mentioned the Ta Yen T'a (the Large Pagoda of the Wild Geese) which was founded in the year 652 by the great Buddhist pilgrim and teacher, Hsüan Chuang. It was then made of clay and brick in five storeys; later on though still in the T'ang period, some storeys were added, and after some vicissitudes, the tower was rebuilt between 931 and 933. Later repairs have been carried out in the Ming and Ch'ing periods. The present pagoda, which has five storeys, seems however to correspond quite well to the T'ang building. It stands on a fairly high terrace and is at the base about 25·5 metres square, its full height being almost 60 metres. Its general shape reminds us of an elongated pyramid with truncated top. The successive storeys, which are accentuated by corbelled cornices, grow lower and narrower towards the top. The uppermost has a pyramidal roof crowned by a glazed cone which is now well covered by small trees and bushes. The coating of the walls is made of yellowish, lightly burnt bricks. They are quite plain except for some very thin pilasters and the arched gateways and a window on each side. The interior division is made by beams and wooden floors and the staircase which still exists makes it possible to ascend to the top. The imposing effect of this tower depends on its fine proportions and well balanced, massive form, which is strengthened by its position on a natural elevation.

Not far from this stands a smaller pagoda called Hsiao Yen T'a (the Small Tower of the Wild Geese), erected 707–709. This tower had originally 15 storeys but of these hardly 13 are now preserved. The storeys are very low but, as in the previous instance, accentuated by corbelled cornices. Only the ground floor is a little higher and on the northern and southern side provided with vaulted entrances. The upper storeys have small vaulted windows on the façade but otherwise no openings or divisions, and it is impossible to know whether they ever had any floors because there is no longer any staircase. Externally the tower differs from the Ta Yen T'a by the fact that it is not a stepped pyramid but a square tower with a slight curve on its middle part.

In still worse repair is the Hsiang Chi Ssu, situated a little farther southward from Sianfu. It was erected in 681 according to the same general design as Hsiao Yen T'a, probably in 11 or more storeys, of which, however, only ten remain. The outline

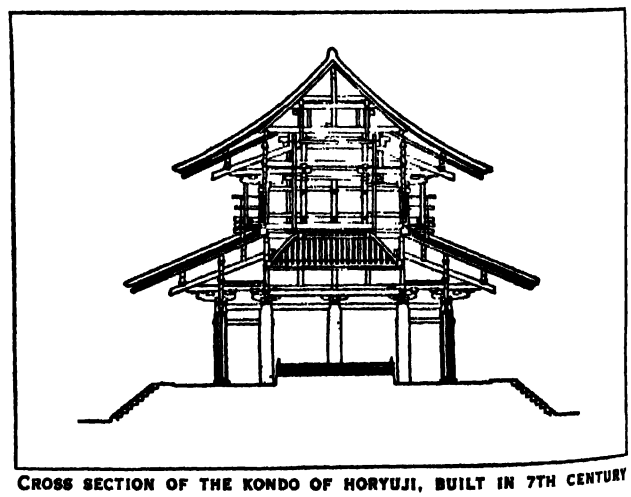


P'ING TZU MEN, INNER GATE-TOWER, PEKING

is not curved but rises straight towards the top which is largely ruined. The storeys are quite low but provided with an horizontal and vertical moulding possibly suggested by wooden buildings. The dependence on wooden architecture is still more evident in another pagoda situated in the same neighbourhood called Hsing Chiao Ssu, which was erected in 839 at the place where the remains of the great pilgrim, Hsüan Chuang, were removed in 669. It is a comparatively small tower measuring only about 20 metres in height and 5·35 on each side, but it presents an unusual historical interest by the fact that some of the most characteristic elements of wooden architecture have here been faithfully reproduced in brickwork. The storeys are not only marked by corbelled cornices but also with rows of three-armed brackets which rise from a kind of horizontal beam and provided furthermore, in the two upper storeys, with carrying posts in the shape of half columns. This close adherence to wood constructions may also be taken as an evidence of the greater age of the wooden pagodas in China as compared with the brick pagodas, which probably were developed through influence from India.

On each side of the Hsing Chia Ssu are smaller three-storeyed pagodas erected to the memory of other monks, both having three divisions without any cornices. Such minor quadrangular towers of three to five storeys dating from the T'ang, Sung and Yüan dynasties are often to be found on tombs or other memorable places. One of the largest and most beautiful among them is the Pai T'a Ssu in the same neighbourhood south of Sianfu; others are to be found at Shen Tung Ssu in Shantung and at Fang Shan in Chihli. The same architectural shape may also be observed in the celebrated pagoda Pai Ma Ssu near Honanfu which was not built until the Sung period, though it often has been mentioned as one of the oldest pagodas in China, probably owing to the legend connected with the Pai Ma Ssu temple. It is supposed to have

been founded by Indian missionaries, who carried the first *sutras* to China, but as a matter of fact, the present pagoda was preceded by an earlier one in wood, which perished by fire in 1126. Other characteristic buildings are the Chiu T'a Ssu, or Nine-towered Pagoda, near Lin Cheng in Shantung, and the Lung Kung T'a at Shen Tung Ssu, an impressive square tower in three high divisions, which are encumbered by sculptural decoration.



CROSS SECTION AND ELEVATION OF YAKUSHIJI PAGODA. 8TH CENTURY

Although the greater part of the buildings which still remain in China from the T'ang and Sung dynasties are pagodas made of mud and brick there are also some examples of temples constructed at least in part of wood, dating from the end of the Sung period. The most authentic and important of these is the Ch'u Tzu An hall at Shao Lin Ssu, the famous temple on the slope of Sung Shan in Honan, where the miraculous Bhodidharma, the founder of the Dhyana or Zen Buddhism, is said to have remained several years. According to an inscription, the Ch'u Tzu An was erected about the year 1125 or shortly before. It is a small, square building (measuring about 11 metres on each side) standing, as usual, on a stone terrace. Each side has four hexagonal stone pillars but only those of the façade are even partly visible, the others being completely embedded in the brick walls. In the room are two pairs of smaller and two pairs of larger hexagonal pillars, all decorated with Buddhist reliefs, and the gateway is framed by carved stone beams. Thanks to these solid stone supports the building still stands, but the roof, which is made of wood, threatens to fall in (if it has not already done so). At the writer's visit to the place in 1921 large pieces of the eaves were missing, and perhaps now the building has no other roof than the sky. The most interesting parts of this structure, however, are not the carved stone pillars but the brackets under the eaves which illustrate how these were used in the Sung period. The modifications in comparison with the bracketing system of the T'ang dynasty are quite noteworthy. Thus we find that the brackets emerge not only from the pillars but also, between these, from the horizontal beam. They are placed more closely together than previously, forming a kind of cornice. In the lower tier the brackets have three arms but in the upper tier the transversal arms have been cut by the under rafters, which are pointed and project like beaks or long paws. They are tied by means of braces to the brackets and carry at both ends struts (vertical posts) on which the purlins or corresponding beams rest. This change may be said to imply that the lower rafters have lost their original character and become a sloping cantilever transversing the lower brackets which they lengthen, thus making them better fitted to support the far projecting roof. The modification has evidently a practical purpose, though it hardly improves the original bracketing system, as exemplified on the T'ang buildings.

The evolution continued in this same direction; the three-armed constructive brackets gave place to two-armed ones transversed by thin sloping beams or rafters, cut like beaks at the end. These project successively, the one tier reaching beyond the other, each one carrying its row of brackets which serve to support the longitudinal beams or a kind of struts for the purlins. The former system may be observed on the Bell Tower at Hsiao Lin Ssŭ, which according to an inscription was erected about the year 1300, where the third storey has no less than four tiers of gradually projecting brackets with beaks. The latter method is quite common; as an example may be mentioned one of the pavilions at the Confucius temple at Chüfu, also of the Yüan dynasty, where the horizontal pieces form a support for several sloping cantilevers (or rudimentary lower rafters) which have been joined into a kind of bed for the struts and purlins of the roof.

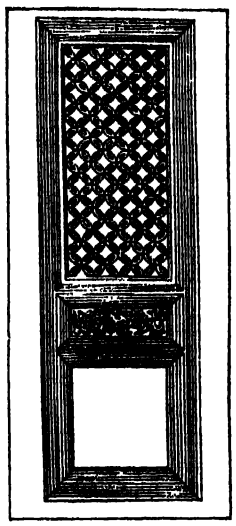
Chinese buildings dating from the Sung and Yüan dynasties are scarce indeed, but our knowledge of the architecture of these

CROSS SECTION OF THE KONDO OF HORYUJI, BUILT IN 7TH CENTURY

times may be supplemented by observations on Japanese buildings from the 12th and 13th centuries, *i.e.*, the Kamakura period. In Japan this was a time of great building activity and, according to the best informed Japanese authorities, remarkable for its close imitation of the contemporary Chinese models. Quite important in this respect is the Shariden (Chu Tsu An) of the Zen temple Engakuji in Kamakura, built according to the same principles as the above-mentioned Chinese hall, though with an

extraordinarily large and high roof covered with straw. This is carried by brackets of the same type as those which were observed at Chu Tsu An of Hsiao Lin Ssu. The brackets are placed so closely together that they form a continuous cornice. The purely Chinese origin of the constructive system of the Shariden of Engakuji may be confirmed through a comparison with some of the illustrations in the above-mentioned architectural treatise *Ying Tsao Fa Shih* published in 1103. On the buildings or schematic designs reproduced here we find brackets of exactly the same type as those described above, though their significance is partly obscured by the addition of some large transverse beams which probably have their origin in the imagination of the draughtsman.

The Japanese called this constructive system which they have borrowed from northern China, "karayo," while another somewhat different contemporary method was called "tenjiku," because it was considered to have been derived from India via southern China. It was used principally at large gates and temple buildings, to which one desired to give a particularly imposing appearance by the development of their upper portions. This was achieved by multiplying the brackets and transforming them into straight arms or cantilevers projecting stepwise from the posts. A good example of the *tenjiku* style is the Nandaimon gate at Todaiji, which was erected in 1199. It has five spans of columns on the long sides and a roof in two storeys, of which the lower one is supported by seven tiers and the upper by six tiers of cantilevers projecting from each column. At the corners are added diagonal cantilevers to form a support for the corner beaks. This kind of construction seems, however, never to have won much popularity in northern China; it is so simple and natural that it hardly can be credited with particular artistic importance. Projecting roof beams have indeed been used in many countries to support the eaves, but the characteristic feature of the *tenjiku* buildings is that the cantilevers are multiplied or massed together by the insertion of intermediate pieces into large composite brackets.



The further development of the wood construction in China after the end of the Yüan dynasty is a question which hardly needs

A STONE ENGRAVING ON THE DOOR GABLE AT TA YAN T'A, SIANFU

to be discussed, because no real progress can be observed, but rather a gradual decline, which becomes evident in the more and more arbitrary treatment of the bracketing system. At the beginning of the Ming dynasty one may still find buildings constructed in the same style as those of the Yüan period, *i.e.*, with beak-formed pieces laid transversally across the brackets, but the projecting pieces become often clumsy and out of proportion to the brackets. A fine example of early Ming architecture is the Bell Tower in Sianfu, the lower roof of which rests on a double row of brackets of the same type as those of the Yüan buildings. On the other hand, the tower of the eastern gate of T'a Tung Fu, erected in 1371, shows beak-shaped pieces projecting from very feeble brackets.

The question how long a really constructive bracketing system remained in use in China is difficult to answer without more detailed investigations than have hitherto been made. It is evident however, that already during the latter half of the Ming period simpler methods were applied, as may be seen for instance on the earliest buildings in the Forbidden City in Peking. It is true that the outer appearance was kept up by fixing multiple rows of brackets and pointed beaks below the eaves, but these have no real constructive function. The purlins rest on projecting beams or on struts standing on the columns. The closely arranged and freely multiplied brackets and beaks which we find on the big palace halls and imposing gate towers in Peking are nothing but ornamental cornices, the decorative effect of which nobody will deny. The roof would indeed rest just as well on the building even if these sham brackets were taken away. The forms are still the same as before but they have lost much of their significance because they lack inner necessity. The particular quality and importance of the old architecture of China depended on its firm and clearly developed wood construction. It was purely carpenters' art, and based on the special requirements of the material. Each part had a definite function which was not concealed by any superimposed decoration. This architecture was logical and purposeful and it remained a living art as long as the original principles of construction were kept up, but once these were encroached upon by purely decorative tendencies, both vitality and further growth were at an end. (*See* also JAPANESE ARCHITECTURE.) (O. S.)

DOOR PANEL ACCORDING TO YING TSAO FA SHIH (1103)

BIBLIOGRAPHY.—The only original Chinese work on architecture is the *Ying Tsao Fa Shi* (1103; 2nd ed., 1145; reissued by the Shanghai Commercial Press). Good accounts of the work were given by P. Demieville in *Bulletin de l'École Française d'Extrême-Orient*, tome XXV. (1925), and Percival W. Yetts in the *Burlington Magazine* (March, 1927), the latter containing a discussion of earlier European books dealing with Chinese architecture. Of greater importance are, however, the works published by various Japanese authorities on their own early buildings since these are closely connected with those of China. See *Japanese Temples and their Treasures* (last ed. 1915); also articles in the *Kokka* and other Japanese reviews, especially C. Ito and J. Tsuchija's report about the imperial palaces in Peking, in the *Bulletin of the School of Engineering of the Tōkyō Imper. University* (1905), a kind of text for the portfolio publications; *Photographs of Palace Buildings of Peking* and *Decoration of the Palace Buildings of Peking* (1906). *See* also Boerschmann, *Baukunst und religiöse Kultur der Chinesen* (1911–14) and *Chinesche Architektur* (1925); Osvald Sirén, *The Walls and Gates of Peking* (1924), and *The Imperial Palaces of Peking* (Paris, 1926); Tokiwa and Sekino, *Buddhist Monuments in China* (Tōkyō, 1926–27), of which only one part has been issued in English.

The drawings of this article are executed partly on the basis of sketches by Prof. Sekino and partly after photographs by the author.

CHINESE EASTERN RAILWAY. In 1895 there was formed, under Russian charter, but with a predominance of French capital and with some capital owned by the Chinese Government, the Russo-Chinese Bank. When, in 1896, Russia obtained from China permission to shorten the Trans-Siberian railway by building a line across Northern Manchuria, the bank formed the Chinese Eastern Railway Company. Only Russians and Chinese were to be shareholders, and a Chinese appointed by Peking was to be president. After 80 years the line was to revert to China free of charge, or the Chinese Government might purchase it at the end of 36 years. The original board of directors was entirely Russian, and the capital stock was all owned by the Russo-Chinese Bank. In 1898 a convention between China and Russia provided for the construction by the company of the South Manchurian line of the Chinese Eastern railway from Harbin to Port Arthur and Dairen (Dalny). The roads so provided for were completed in 1905 and for that purpose the Russian Government advanced about 800,000,000 roubles. In 1905, as a result of the Russo-Japanese War, the South Manchurian railway south of Changchun passed into the hands of Japan.

In 1910 the Russo-Chinese Bank was amalgamated with the Northern Bank to form the Russo-Asiatic Bank, and the new institution became heir of the Russo-Chinese Bank's interest in the Chinese Eastern railway. The new bank had a Russian charter, but the majority of its stock was in French hands. The Chinese government remained a part owner. In 1915 an agreement was formed for the operation by the Chinese Eastern railway of the short private line connecting Tsitsihar and the main line, and in March 1916 an agreement was entered into by the Russo-Asiatic Bank and the Chinese government for the building of a line from Harbin to Blagovyeshchensk with a branch from Mergen to Tsitsihar. In a treaty of July 3, 1916, Russia ceded to Japan 60 mi. of the Chinese Eastern railway between Changchun and the Sungari river.

World War I and the Russian Revolution and the consequent disintegration in Siberia threw the traffic and finances of the railway into confusion.

In pursuance of the Chino-Japanese military agreement of 1918, made after China entered World War I, Japanese troops appeared in the Chinese Eastern railway zone. Largely at the insistence of the United States, and to save the line from the Japanese, an international, interallied commission was appointed to operate the road. This control lasted until 1922. The Chinese saw in the disturbed conditions an opportunity to extend their control over the railway, and beginning in 1920 for a time successfully asserted themselves.

At the Washington conference in 1921–22, a resolution was adopted stating that better protection should be given the railway, that the personnel should be more carefully selected, and the funds more economically used. The powers other than China also made reservations under which the consular body in Harbin interfered when in Aug. 1923 the Chinese attempted to seize the land department of the railway.

The Russo-Chinese agreement of May 31, 1924, contained a long article which, among other things, had an assurance that China might buy back the railway and a provision for a conference to settle more definitely the future of the road. Simultaneously, another agreement was adopted for the joint administration of the railway pending the final adjustment.

In July 1929, sharp dissension culminated in the seizure of the road by the Chinese. A Russian invasion, however, compelled the restoration of the *status quo*.

After the establishment of the Japanese-dominated state of Manchoukuo relations between the joint owners became strained. To remove the friction, negotiations were begun in 1933 for the sale of Russia's share. These resulted in an agreement, Sept. 19, 1934, whereby Manchoukuo was to pay the equivalent of 140,000,000 yen (1 yen=$.4985 at par), one-third in cash and the remainder in kind. The transfer was completed March 23, 1935. The road was renamed the North Manchurian railway and became part of the system operated by the (Japanese) South Manchuria Railway company. Renamed the Chinese Changchun railway, the Manchurian rail system was jointly controlled by China and the U.S.S.R. after World War II.

As part of a series of agreements signed between the Chinese People's Republic and the U.S.S.R. in Moscow on Feb. 14, 1950, the U.S.S.R. promised to transfer the full ownership and control of the Chinese Changchun railway to China. The transfer became effective on Dec. 31, 1952. (K. S. L.; X.)

CHINESE EMIGRATION. From the fact that in 1718 the Chinese government banned emigration, it may be inferred that some Chinese had left for neighbouring countries, but there were no reliable statistics for about another century, when Chinese emigration, especially to other Asiatic lands, increased greatly. Overpopulation, wars, famines, political unrest, lawlessness, low wages, high land prices and recruitment of labourers by foreigners exerted pressures that account for Chinese migration until it was restricted or prohibited by the receiving countries.

From 1820, when one Chinese entered the United States, until the middle of the 19th century, fewer than 100 Chinese went to the United States; but with the gold rush that started in California in 1849 there began a period of increased Chinese immigration, especially to California, which made Chinese immigration a dominant issue in California politics from 1860 to 1890. For a time the immigrants were welcomed as cheap labour that was needed for the menial tasks of a pioneering, aggressive community preoccupied with railroad building and gold prospecting; but when unemployment developed, the welcome turned into racial animosity and agitation for state and national restrictive or exclusionary measures.

It was charged that the immigrants were unassimilable and subject to grave personal vices. For their part, the immigrants complained that they were excluded from the rest of society by discriminatory laws and customs.

The Burlingame treaty of 1868 gave Chinese subjects in the United States the right to privileges enjoyed by citizens of the most-favoured nation, but soon this treaty was effectively abrogated by congressional acts, the constitutionality of which was upheld by the supreme court. In 1879 congress passed a bill to exclude Chinese labourers; it was vetoed by the president. In 1882 congress passed an act to suspend Chinese immigration for ten years. An act of 1892 extended the suspension for another ten years. In 1902 the statutory policy became one of permanent exclusion. In a message to congress, Pres. Franklin D. Roosevelt asked for an end of this policy, and in 1943 congress complied (at that time China was an ally of the United States in World War II and was to be one of the Big Five of the projected United Nations). The Immigration and Nationality act of 1952 repealed all racial exclusionary provisions except that (1) persons who are related by as much as one-half of their ancestry to peoples indigenous to an Asia-Pacific triangle, defined by the act, are charged, for immigration quota purposes, to the countries of Asia, wherever they may have been born or however long their ancestors may have made their homes outside the land of their origin; and (2) a quota limit of 100 was placed on entries from any colony. The former provision assured that immigrants of Chinese descent regardless of nationality, are not to exceed the annual Chinese quota of 105.

Despite restrictions, from 1820 to 1949, 397,602 Chinese immigrants were admitted into the United States; and of this total, 50,264 were admitted in the years 1921–1949, the so-called restrictive period of U.S. immigration policy, and 118,393 in the selective period 1881–1920.

Available statistics for the number of Chinese residing abroad show that the largest migrations from China were to other Asiatic countries, and the smallest were to Europe. Thus (the figures are for 1922) Burma had 134,600; the East Indies, 1,023,500; Formosa, 2,258,650; Java, 1,825,700; Korea, 11,310; Siam, 1,500,000; Straits Settlements, 432,764; and the Philippines, 55,212. Australia had 35,000. Brazil had 20,000; Canada, 12,000; Cuba, 90,000; Mexico, 3,000; Peru, 45,000. South Africa had 5,000, and all of Europe, only 1,760. A total of more than 8,000,000 Chinese resided abroad. In the 1920s and 1930s there was a considerable Chinese migration to Manchuria—nearly 1,000,000 went there in 1928, and from 1925 to 1929 at least 2,000,000 settled there. Chinese immigration has been prohibited by the statutes or administrative action of many countries, among them Canada and Australia.

Chinese immigration to occidental countries failed to bring about distinctive, lasting effects upon the culture of the receiving countries. This may be explained by the inimical acts of the occidental peoples which permitted but few contacts. Immigration restrictions have, however, reduced tensions; Chinatowns are disappearing, and the Chinese are becoming absorbed in the general life of the community, leaving no specific significant trace of their own culture.

(M. R. K.)

CHINESE LANGUAGE. In treating of Chinese, it will be convenient to distinguish, broadly, the spoken from the written language because for reasons connected with the peculiar nature of the script, the two soon began to move along independent and largely divergent lines.

Although Chinese, like other living languages, must have undergone gradual changes in the past, so little can be stated with certainty about these changes that an accurate survey of its evolution is quite out of the question. Obviously a different method is required when we come to the written characters. We have hardly any clue as to how Chinese was spoken or pronounced in any given district 2,000 years ago, although there are written remains dating from long before that time; and in order to gain an insight into the structure of the characters now existing, it is necessary to trace their origin and development.

We find a number of dialects, all clearly of a common stock, yet differing widely from one another. Most of these dialects fringe the coast-line of China, and penetrate but a comparatively short way into the interior. Starting from the province of Kwangtung in the south, where the Cantonese and, farther inland, the Hakka dialects are spoken, and, proceeding northwards, we pass in succession the following dialects: Swatow, Amoy (these two may almost be regarded as one), Foochow, Wenchow, Ningpo and Wu. Farther north the great dialect popularly known as Mandarin (*Kuanhua* or "official language"), sweeps round behind the narrow strip of coast occupied by the various dialects above-mentioned, and dominates a hinterland constituting nearly four fifths of China proper. Mandarin, of which the dialect of Peking, the capital 1421 to 1928, is now the standard form, comprises a considerable number of sub-dialects, some of them so closely allied that the speakers of one are wholly intelligible to the speakers of another, while others (*e.g.*, the vernaculars of Yangchow, Hankow or Mid-China and Ssŭ-ch'uan) may almost be considered as separate dialects. Cantonese is supposed to approximate most nearly to the primitive language of antiquity, whereas Pekingese perhaps has receded farthest from it. For all practical purposes Mandarin, in the widest sense of the term, is by far the most important as the native speech of the majority of Chinese and the recognized vehicle of oral communication between all Chinese officials, even when they come from the same part of the country and speak the same *patois*. All examples of phraseology in this article will therefore be given in Pekingese.

The dialects proceed from the same parent stem, are spoken by members of the same race, are united by the bond of writing, the common possession of all, and share alike in the two most salient features of Chinese as a whole: (1) they are all monosyllabic, that is, each individual word consists of only one syllable; and (2) they are strikingly poor in vocables, or separate sounds for the conveyance of speech. The number of these vocables varies from between 800 and 900 in Cantonese to no more than 420 in the vernacular of Peking. This scanty number is eked out by interposing an aspirate between certain initial consonants and the vowel, so that for instance *p'u* is distinguished from *pu*. The latter is pronounced with little or no emission of breath, the "p" approximating the farther north one goes (*e.g.*, at Niuchwang) more closely to a "b." The aspirated *p'u* is pronounced more like our interjection "Pooh!" The number of vocables in Pekingese has slowly but surely diminished. Thus the initials *ts* and *k*, when followed by the vowel *i* (with its continental value) have gradually become softer and more assimilated to each other, and are now both pronounced *ch*. Again, all consonantal endings in *t* and *k*, such as survive in Cantonese and other dialects, have entirely disappeared from Pekingese, and *n* and *ng* are the only final consonants remaining. Vowel sounds, on the other hand, have been proportionately developed, such compounds as *ao*, *ia*, *iao*, *iu*, *ie*, *ua* occurring with especial frequency. One and the same sound has therefore to do duty for different words. Some sounds may have fewer meanings than ten attached to them, but others will have many more. Thus the following represent only a fraction of the total number of words pronounced *shih* (something like the "shi" in shirt): 史 "history," 使 "to employ," 屍 "a corpse," 市 "a market," 師 "an army," 獅 "a lion," 恃 "to rely on," 侍 "to wait on," 詩 "poetry," 時 "time," 識 "to know," 施 "to bestow," 是 "to be," 實 "solid," 失 "to lose," 示 "to proclaim," 視 "to look at," 十 "ten," 拾 "to pick up," 石 "stone," 世 "generation," 食 "to eat," 室 "a house," 氏 "a clan," 始 "beginning," 釋 "to let go," 試 "to test," 事 "affair," 勢 "power," 士 "officer," 誓 "to swear," 逝 "to pass away," 適 "to happen."

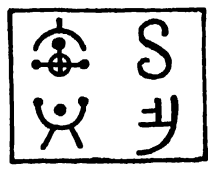
Use of Couplets.—To supplement this deficiency of sounds several devices are employed through the combination of which confusion is avoided. One of these devices is the coupling of words in pairs in order to express a single idea. There is a word 哥 *ko* which means "elder brother." But in speaking, the sound *ko* alone would not always be easily understood in this sense. One must either reduplicate it and say *ko-ko*, or prefix 大 (*ta*, "great") and say *ta-ko*. Simple reduplication is mostly confined to family appellations and such adverbial phrases as 慢慢 *man-man*, "slowly." But in a much larger class of pairs, each of the two components has the same meaning. Examples are: 恐怕 *k'ung-p'a*, "to be afraid," 告訴 *kao-su*, "to tell," 樹木 *shu-mu*, "tree," 皮膚 *p'i-fu*, "skin," 滿盈 *man-ying*, "full," 孤獨 *ku-tu*, "solitary." Sometimes the two parts are not exactly synonymous, but together make up the sense required. Thus in 衣裳 *i-shang*, "clothes," *i* denotes more particularly clothes worn on the upper part of the body, and *shang* those on the lower part. In another very large class of expressions, the first word serves to limit and determine the special meaning of the second: 奶皮 "milk-skin," "cream"; 火腿 "fire-leg," "ham"; 燈籠 "lamp-cage," "lantern"; 海腰 "sea-waist," "strait." There are, besides, a number of phrases which are harder to classify. Thus, 虎 *hu* means "tiger." But in any case where ambiguity might arise, *lao-hu*, "old tiger," is used instead of the monosyllable. 狐 (another *hu*) is "fox," and 狸 *li*, an animal belonging to the smaller cat tribe. Together, *hu-li*, they form the usual term for fox. 知道 *chih tao* is literally "to know the way," but has come to be used simply for the verb "to know." These pairs or two-word phrases are of such frequent occurrence, that the Chinese spoken language might almost be described as bi-syllabic. Suffixes or enclitics are attached to many of the commonest nouns. 女 *nü* is the word for "girl," but in speech 女子 *nü-tsŭ* or 女兒 *nü-'rh* is the form used. 子 and 兒 both mean child, and must originally have been diminutives. The suffix 兒 belongs especially to the Peking vernacular. The use of numeratives is quite a distinctive feature of the language. The commonest of them, 個 *ko*, can be used indifferently in connection with almost any class of things, animal, vegetable or mineral. But there are other numeratives (at least 20 or 30 in everyday use) which are strictly reserved for limited classes of things with specific attributes. 枚 *mei*, for instance, is the numerative of circular objects such as coins and rings; 顆 *k'o* of small globular objects—pearls, grains of rice, etc.; 口 *k'ou* classifies things which have a mouth—bags, boxes and so forth; 件 *chien* is used of all kinds of affairs; 張 *chang* of chairs and sheets of paper; 隻 *chih* (literally half a pair) is the numerative for various animals, parts of the body, articles of clothing and ships; 把 *pa* for things which are grasped by a handle, such as fans and knives.

The Tones.—The tones may be defined as regular modulations of the voice by means of which different inflections can be imparted to the same sound. To the foreign ear, a Chinese sentence spoken slowly with the tones clearly brought out has a certain sing-song effect. It is absurd to suppose the tones were deliberately invented in order to fit each written character with a separate sound. It is considered that tones were the automatic result of the elision of prefixes, some of which as elsewhere may have served as classifiers. A tone is as much an integral part of the word to which it belongs as the sound itself; like the sound, too, it is not fixed once and for all, but is in a constant, though

very gradual state of evolution. This is proved by the great differences of intonation in the dialects. Theoretically, four tones have been distinguished (the even, the rising, the sinking and the entering) each of which falls again into an upper and a lower series. But only the Cantonese dialect possesses all these eight varieties of tone (to which a ninth has been added), while Pekingese has only four: the even upper, the even lower, the rising and the sinking. It appears that down to the 3rd century B.C. the only tones distinguished were the 平 "even," 上 "rising" and 入 "entering" Between that date and the 4th century A.D. the 去 sinking tone was developed. In the 11th century the even tone was divided into upper and lower, and a little later the entering tone finally disappeared from Pekingese. For centuries their existence was unsuspected, the first systematic classification of them being associated with the name of Shên Yo, a scholar who lived A.D. 441–513. The Emperor Wu Ti one day said to him: "Come, tell me, what are these famous four tones?" "They are 天子聖哲 whatever your Majesty pleases to make them," replied Shên Yo, skilfully selecting for his answer four words which illustrated, and in the usual order, the four tones in question. Not every single word in a sentence must necessarily be given its full tonic force. Quite a number of words, such as the enclitics, are not intonated at all. In others the degree of emphasis depends partly on the tone itself, partly on its position in the sentence. In Pekingese the 3rd tone (really the 2nd in the ordinary series, the 1st being subdivided into upper and lower) is particularly important, and next to it in this respect comes the 2nd (that is, the lower even, or 2nd division of the 1st). It may be said, roughly, that any speaker whose 2nd and 3rd tones are correct will at any rate be understood, even if the 1st and 4th are slurred over.

The Characters.—A page of printed Chinese or carefully written manuscript consists of a number of wholly independent units, each of which would fit into a small square, and is called a character. These characters are arranged in columns, beginning on the right-hand side of the page and running from top to bottom. They are *words*, standing for articulate sounds expressing root-ideas, but, unlike our words, are not composed of alphabetical elements or letters. Clearly, if each character were a distinct and arbitrarily constructed symbol, only those gifted with exceptional powers of memory could ever hope to read or write with fluency. This, however, is far from being the case. Most Chinese characters are susceptible of some kind of analysis. Means of communication other than oral began with the use of knotted cords, similar to the *quipus* (*q.v.*) of ancient Mexico and Peru, and were displaced later on by the practice of notching or scoring rude marks on wood, bamboo and stone. The first four numerals, as written with simple horizontal strokes date from this early period. In Chinese writing, a few characters, even in their present form are pictures of objects, pure and simple. Thus, for "sun" the ancient Chinese drew a circle with a dot in it: ⊙, now modified into 日; for "moon"  , now 月; for "God" they drew the anthropomorphic figure  , which in its modern form appears as 天; for "mountains"  , now 山; for "child"  , now 子; for "fish"  , now 魚; for "mouth" a round hole, now 口;  for "hand" now 手; for "well"  , now written without the dot. These picture-characters, then, accumulated little by little, until they comprised all the common objects which could be easily and rapidly delineated—sun, moon, stars, various animals, certain parts of the body, tree, grass and so forth to the number of two or three hundred. The next step was to a few compound pictograms: 旦 the sun just above the horizon = "dawn"; 林 trees side by side = "a forest"; 舌 a mouth with something solid coming out of it = "the tongue"; 言 a mouth with vapour or breath coming out of it = "words."

While writing was still in its infancy, it must have occurred to the Chinese to join together two or more pictorial characters in order that their association might suggest to the mind some third thing or idea? "Sun" and "moon" combined in this way make the character 明, which means "bright"; woman and child make 好 "good"; "fields" and "strength" (that is, labour in the fields) produce the character 男 "male"; the "sun" seen through "trees" 東 designates the east; 家 has been explained as (1) a "pig" under a "roof," the Chinese idea, common to the Irish peasant, of home, and also (2) as "several persons" under "a roof," in the same sense; a "woman" under a "roof" makes the character 安 "peace"; "words" and "tongue" 話 naturally suggest "speech"; two hands (友, in the old form ) indicate friendship; "woman" and "birth" 姓 = "born of a woman," means "clan-name," showing that the ancient Chinese traced through the mother and not through the father. This class of characters, correctly called ideograms, as representing ideas and not objects, is comparatively small. As there was nothing in the character *per se* which gave the slightest clue to the sound of the word it represented, each character had to be learned and recognized by a separate effort of memory. The first step in a new, and, ultimately the right direction, was the borrowing of a character already in use to represent another word identical in sound, though different in meaning. Owing to the scarcity of vocables there might be as many as ten different words in common use, each pronounced *fang*. Out of those ten only one, we will suppose, had a character assigned to it—viz., 方 "square" (originally said to be a picture of two boats joined together). But among the other nine was *fang*, meaning "street" or "locality," in such common use that it became necessary to have some means of writing it. Instead of inventing an altogether new character, as they might have done, the Chinese took 方 "square" and used it also in the sense of "locality." This was a simple expedient, no doubt, but one that applied on a large scale would lead to confusion. The difficulty which presented itself was overcome as in speech by adding to *fang* "square," another part meaning "earth," in order to show that the *fang* in question had to do with location on the earth's surface. The whole character thus appeared as 坊. Nothing was easier now than to provide signs for the other words pronounced *fang*. "A room" was 房 door-*fang*; "to spin" was 紡 silk-*fang*; "fragrant" was 芳 herbs-*fang*; "to enquire" was 訪 words-*fang*; "an embankment," and hence "to guard against," was 防 mound-*fang*; "to hinder" was 妨 woman-*fang*. This class of characters, which constitutes at least nine-tenths of the language, has received the convenient name of *phonograms*. The formation of the phonogram, or phonetic compound, did not always proceed along such simple lines as in the examples given above. In the first place, most of the phonetics now existing are not simple pictograms, but themselves more or less complex characters made up in a variety of ways. Again, the sound is in most cases given by no means exactly by the so-called phonetic, a fact chiefly due to the pronunciation having undergone changes which the written character was incapable of recording. There are extreme cases in which a phonetic provides hardly any clue at all as to the sound of its derivatives. In general, the "final" or rhyme is pretty accurately indicated, while in not a few cases the phonetic does give the exact sound for all its derivatives. A considerable number of phonetics are nearly or entirely obsolete as separate characters, although their family of derivatives may be a very large one. 臤, for instance, is never seen by itself, yet 堅 緊, and 賢 are among the most important characters in the language.



The whole body of Chinese characters, then, may conveniently be divided up, for philological purposes, into pictograms, ideograms and phonograms. The first are pictures of objects, the second are composite symbols standing for abstract ideas, the third are compound characters of which the more important element simply represents a spoken sound. In a strict sense, even the first two classes do not directly represent either objects or ideas, but rather stand for sounds by which these objects and ideas have previously been expressed. It may, in fact, be said that Chinese characters are "nothing but a number of more or

less ingenious devices for suggesting spoken words to a reader."

The "Six Scripts."—The Chinese themselves at a very early date (probably many centuries B.C.) evolved a six-fold classification of characters, the so-called 六書 *liu shu*, very inaccurately translated by the Six Scripts, which may be briefly noticed:—

1. 指事 *chih shih*, indicative or self-explanatory characters. This is a very small class, including only the simplest numerals and a few others such as 上 "above" and 下 "below."
2. 象形 *hsiang hsing*, pictographic characters.
3. 形聲 *hsing shêng* or 諧聲 *hsieh shêng*, phonetic compounds.
4. 會意 *hui i*, suggestive compounds based on a natural association of ideas. To this class alone can the term "ideographs" be properly applied.
5. 轉注 *chuan chu*. The meaning of this name has been much disputed, some saying that it means "turned round"; *e.g.*, 目 *mu* "eye" is now written 目. Others understand it as comprising a few groups of characters nearly related in sense, each character consisting of an element common to the group, together with a specific and detachable part; *e.g.*, 老, 考 and 耆, all of which have the meaning "old." This class is concerned only with peculiarities in the use of characters.
6. 假借 *chia chieh*, borrowed characters, that is, characters adopted for different words simply because of the identity of sound. The period of "borrowed characters" did not last very long, though traces of it are thought to be seen in the habit of writing several characters, especially those for certain plants and animals, indifferently with or without their radicals.

Styles of Writing.—In the earliest inscriptions (Shang dynasty, 18th century B.C.), the so-called 古文 *ku-wen* or "ancient figures," all the above-mentioned forms occur. None are wholly pictorial, with one or two unimportant exceptions. In the following specimen only the last character is unmistakably pictorial:

This is read: 申作寶鼎 "Shên made [this] precious *ting*." In 1903 a large number of inscribed bone fragments were excavated in the north of China, which have furnished a list of nearly 2,500 separate characters, of which not more than about 600 have been so far identified. They appear to be responses given by professional soothsayers to private individuals who came to them seeking the aid of divination in the affairs of their daily life. The bones were ancient but some at least of the inscriptions have been forged. It is difficult to fix their date with much exactitude. The script, though less archaic than that of the earlier bronzes, is of an exceedingly free and irregular type. Some attribute them to the Shang, or Yin dynasty (1765–1122 B.C.) in accord with Chinese tradition. Others think that they represent a mode of writing already obsolete at the time of their production, and retained of set purpose by the diviners from obscurantist motives, dating them about 500 years later, or only half a century before the birth of Confucius, long after the appearance of a new and more conventionalized form of writing, called in Chinese 篆 *chuan*, which is commonly rendered by the word Seal, for the reason that many ages afterwards it was generally adopted for use on seals. Under the Chou dynasty, as well as the two succeeding it, the meaning of the word was not "seal," but "sinuous curves," as made in writing. This epoch possibly marks the first introduction into China of the brush in place of the bamboo or wooden pencil with frayed end which was used with some kind of colouring matter or varnish, and the introduction of a supple implement like the brush at the very time when the forms of characters were fast becoming crystallized and fixed, would account for a great revolution in the style of writing. Authentic specimens of the 大篆 *ta chuan*, older or Greater Seal writing, are exceedingly rare. But it is generally believed that the inscriptions on the famous stone drums, now at Peking, date from the reign of King Hsüan, and they may therefore with practical certainty be cited as examples of the Greater Seal in its original form. These "drums," really ten roughly chiselled mountain boulders, were discovered in the early part of the 7th century, lying half buried in the ground near Fêng-hsiang Fu in the province of Shensi. On them are engraved ten odes, a complete ode being cut on each drum, celebrating an imperial hunting and fishing expedition in that part of the country. Great strides had been made in this writing towards symmetry, compactness and conventionalism. The vogue of the Greater Seal appears to have lasted until the reign of the First Emperor, 246–210 B.C. (*see* CHINA: *History*), when further modification took place. For centuries China had been split into a number of practically independent States, and this circumstance seems to have led to considerable variations in the styles of writing. Having unified the empire, the First Emperor proceeded, on the advice of his minister Li Ssŭ, to standardize its script by ordaining that only the style in use in his own State of Ch'in should henceforward be employed throughout China. This new style of writing was the Greater Seal characters in the form they had assumed after several centuries of evolution, with numerous abbreviations and modifications. It was afterwards known as the 小篆 *hsiao chuan*, or Lesser Seal, and is familiar from the *Shuo Wên* dictionary. Though an improvement on what had gone before, something less cumbrous was felt to be necessary by the clerks who had to supply the immense quantity of written reports demanded by the First Emperor. Thus a simpler and more artistic form of writing was in use, though not universally, not long after the decree abolishing the Greater Seal. This 隸書 *li shu*, or "official script," as it is called, shows a great advance on the Seal character. It is perhaps likely to have been directly evolved from the Greater Seal. It differs from the modern character only in minor details. The Lesser Seal was evidently obsolete at the time of the compilation of the *Shuo Wên*, about 100 years after the Christian era. The Greater Seal and still earlier forms of writing had fallen into utter oblivion before the Han dynasty was 50 years old.

Out of the "official script" two other forms were soon developed, viz., the 草書 *ts'ao shu*, or "grass character" which so curtails the usual strokes as to be comparable to a species of shorthand, requiring special study, and the 行書 *hsing shu* or running hand, used in ordinary correspondence. Some form of grass character is mentioned as in use as early as 200 B.C. or thereabouts, though how nearly it approximated to the modern grass hand it is hard to say; the running hand seems to have come several centuries later. The final standardization of Chinese writing was due to the great calligraphist Wang Hsi-chih of the 4th century, who gave currency to the graceful style of character known as 楷書 *k'ai shu*, sometimes referred to as the "clerkly hand." When block-printing was invented some centuries later, the characters were cut on this model, which still survives at the present day. The script of China has remained practically unchanged ever since. The manuscript rolls of the T'ang and preceding dynasties, discovered by Sir Aurel Stein in Turkestan, show a style of writing not only clear and legible but remarkably modern in appearance.

Grammar.—No set of rules governing the mutual relations of words has ever been formulated by the Chinese, apparently because the need of such rules has never been felt. The most that native writers have done is to draw a distinction between 實字 and 虛字 "full" and "empty words," respectively, the former being subdivided into 活字 "living words" or verbs, and 死字 "dead words" or noun-substantives. By "empty words" particles are meant, though sometimes the expression is loosely applied to abstract terms, including verbs. The above meagre classification is their nearest approach to a conception of grammar in our sense. Every Chinese character is an indivisible unit, representing a sound and standing for a root-idea. Being free from inflection or agglutination of any kind it is incapable of indicating in itself either gender, number or case, voice, mood, tense or person. No Chinese character can be definitely regarded as being any particular part of speech or possessing any particular

function absolutely, apart from the general tenor of its context. Thus, taken singly, the character 上 conveys only the general idea "above" as opposed to "below." According to its place in the sentence and the requirements of common sense, it may be a noun meaning "upper person" (that is, a ruler); an adjective meaning "upper," "topmost" or "best"; an adverb meaning "above"; a preposition meaning "upon"; and finally a verb meaning "to mount upon," or "to go to." It would puzzle grammarians to determine the precise grammatical function of any of the words in the following sentence, with the exception of 何 (an interrogative, by the way, which here happens to mean "why" but in other contexts is equivalent to "how," "which" or "what"): 事何必古 "Affair why must ancient," or in more idiomatic English, "Why necessarily stick to the ways of the ancients in such matters?" Or take a proverbial saying like 少所見多所怪 which may be correctly rendered "The less a man has seen the more he has to wonder at." It is one thing, however, to translate it correctly, and another to explain how this translation can be inferred from the individual words, of which the bald equivalents might be given as: "Few what see, many what strange." To say that "strange" is the literal equivalent of 怪 does not mean that 怪 can be definitely classed as an adjective. On the other hand, it would be dangerous even to assert that the word here plays the part of an active verb, because it would be equally permissible to translate the above, "Many things are strange to one who has seen but little."

There are certain positions and collocations of words which tend to recur, but the number of qualifications and exceptions which will have to be added is so great as to render the rule itself valueless. 馬上 means "on a horse," 上馬 "to get on a horse." But it will not do to say that a preposition becomes a verb when placed before the substantive, as many other prepositions come before and not after the words they govern. If we meet such a phrase as 警寇, literally "warn rebels," we must not mentally label 警 as a verb and 寇 as a substantive, and say to ourselves that in Chinese the verb is followed immediately by its object. Otherwise, we might be tempted to translate, "to warn the rebels," whereas a little reflection would show us that the conjunction of "warning" and "rebels" naturally leads to the meaning "to warn (the populace or whoever it may be) *against* the rebels." Each particular passage is best interpreted on its own merits, by the logic of the context and the application of common sense. The beginner must accustom himself to look upon each character as a root-idea, not a definite part of speech.

The Book Language.—In the beginning, all characters doubtless represented spoken words, but there was no need to reproduce in writing the bisyllabic compounds of common speech because *chien* "to see," in its written form 見, could not possibly be confused with any other *chien*, and it was therefore unnecessary to go to the trouble of writing 看見 *k'an-chien* "look-see," as in colloquial. All superfluous particles or other words that could be dispensed with were ruthlessly cut away, and all the old classical works were composed in the tersest of language, far removed from the speech of the people. The passion for brevity and conciseness resulted often in such obscurity that detailed commentaries on the classics have always constituted an important branch of Chinese literature. After the introduction of the improved style of script, and when the mechanical means of writing had been simplified, literary diction became freer and more expansive, to some extent, but the classics were held in such veneration as to exercise the profoundest influence over all succeeding schools of writers, and the divorce between literature and popular speech became permanent. No book of any first-rate literary pretensions would be easily intelligible to any class of Chinese, educated or otherwise, if read aloud exactly as printed. The public reader of stories is obliged to translate, so to speak, into the colloquial of his audience as he goes along. There is no inherent reason why the conversation of every-day life should not be rendered into characters, as is done in foreign handbooks for teaching elementary Chinese; one can only say that the Chinese do not think it worth while. There are a few words, indeed, which, though common enough in the mouths of genteel and vulgar alike, have positively no characters to represent them. On the other hand, there is a vast store of purely book words which would never be used or understood in conversation.

The book language is nice in its choice of words, and obeys special rules of construction. Of these, perhaps the most apparent is the carefully marked antithesis between characters in different clauses of a sentence, which results in a kind of parallelism of rhythmic balance. This parallelism is a noticeable feature in ordinary poetical composition, and may be well illustrated by the following four-line stanza: "白日依山盡 The bright sun completes its course behind the mountains; 黃河入海流 The yellow river flows away into the sea. 欲窮千里目 Would you command a prospect of a thousand *li*? 更上一層樓 Climb yet one storey higher." In the first line of this piece, every single character is balanced by a corresponding one in the second: 白 white by 黃 yellow, 日 sun by 河 river, and so on. In the 3rd and 4th lines, where more laxity is generally allowed, every word again has its counterpart, with the sole exception of 欲 "wish" and 更 "further." Some of the early Jesuit missionaries, men of great natural ability who steeped themselves in Oriental learning, have left very different opinions on record. Chinese appeared to be as admirable for the superabundant richness of its vocabulary as for the conciseness of its literary style. And among modern scholars there is a decided tendency to accept this view as embodying a great deal more truth than the other.

The Chinese language has to assimilate the vast stock of new terminology which closer contact with the West would necessarily carry with it, by the conjunction of two or more characters already existing; of this 昇降機 (rise-descend-machine) for "lift," and 議政國會 (discuss-govern-country-assembly) for "parliament" are examples. Even a metaphysical abstraction like the Absolute has been tentatively expressed by 絕對 (exclude-opposite); but in this case an equivalent was already existing in the Chinese language.

A drastic measure, strongly advocated in some quarters, is the entire abolition of all characters, to be replaced by their equivalent sounds in letters of the alphabet. Under this scheme 人 would figure as *jên* or *ren*, 馬 as *ma*, and so on. But the proposal has fallen extremely flat. The vocables are so few that only the colloquial, if even that, could possibly be transcribed in this manner. Any attempt to transliterate classical Chinese would result in a mere jumble of sounds, utterly unintelligible, even with the addition of tone-marks. There is another aspect of the case. The characters are a potent bond of union between the different parts of the country with their various dialects, and the script, in spite of certain disadvantages, has hitherto triumphantly adapted itself to the needs of civilized intercourse.

Giles, *A Chinese-English Dictionary* (2nd ed., 1910); B. Karlgren, *Sound and Symbol in Chinese* (1923).

CHINESE LITERATURE is not the oldest in the world, but it has the longest history of any written in a single language, continuously producing works of historical, intellectual and artistic interest for more than 2,500 years. The people's speech varied in different areas and changed with time, but because of the nature of their writing (*see* CHINESE LANGUAGE) and the early standardization of orthography, educated persons could read the national literature no matter where or when it was written.

Writing in the living language was a late development, and although masterpieces appeared in it, for a thousand years they remained outside the four standard Chinese categories of literature. These were:

The Classics.—These refer not to great writings throughout Chinese history, but to the heterogeneous scriptures (*ching*) mak-

ing up the canon of the Confucian school of thought. They derive their status from association (in part actual, in part contrived much later) with Confucius himself (550 or 551–479 B.C.). It is certain that he used some form of the *Shu Ching* (*Classic of Documents*) and *Shih Ching* (*Classic of Songs*) in his teachings, less certain that he set great store by the *I Ching* (*Classic of Divination*). He probably compiled the *Ch'un Ch'iu* (*Springs and Autumns*), a bare chronicle of his native state of Lu which, accompanied by three early commentaries, accounts for three among the classics. The *Tso Chuan* probably was not a commentary in origin, being largely narrative; its literary interest is considerable.

The remarks of Confucius and some of his students are preserved in elliptical style in the *Lun Yü* (*Analects*). His later admirer Mencius was similarly immortalized in the more fluent book *Meng Tzu*, which likewise eventually became a classic. Since the 12th century these two texts have been associated with the *Ta Hsüeh* (*Great Learning*) and *Chung Yung* (*Happy Mean*) in a group constituting the four books emphasized by the neo-Confucians (*see* below, *Philosophical Works*). The latter two are really chapters extracted from the *Li Chi*, one of three classic collections of public and private ritual compiled toward the time of Christ, as was the *Erh Ya*.

This is a kind of lexicon, perhaps deriving its canonical status from a Chinese concept of the nature and power of the word—spoken or written—almost as mystical as the Christian concept of the Logos. Last but not least influential of the 13 classics is the spurious *Hsiao Ching* (*Classic of Filial Piety*). All are accompanied by numerous, sometimes divergent commentaries and subcommentaries.

Forming the core of education for government service (the primary aim of all education in prerepublican China), the classics permeated Chinese life. Their historical and philological importance is great, but except for the *Songs* (*see* below, *Poetry*) their intrinsic literary interest is far outweighed by their influence on later writings, which are often incomprehensible without recognition of their allusions to the classics. Chinese literary theory related all subsequently acknowledged literary forms to one or another of the classics.

Historical Writings, Including Biographies, Travelogues, Geographies, etc.—Historiography derives from the *Classic of Documents* through the *Springs and Autumns* chronicle. The so-called commentary *Tso Chuan* and other works of its period undoubtedly contain some genuine historical data. The first general history of China was the *Shih Chi* (*Historian's Records*) of Ssu-ma Ch'ien (145–?87 B.C.), who to some extent rationalized legend and proceeded with increasing historicity down to his own Han times. The monumental work was substantially a selection of extant texts, to which the compiler appended his own judgments. His method set the pattern for most subsequent histories, which were divided into (1) annals of imperial reigns; (2) tables of government organization, etc.; (3) treatises on such subjects as the calendar, economy and geography; and (4) biographies. Pan Ku (A.D. 32–92) intended his *History of the Han Dynasty* as a continuation of the *Historian's Records*. Each later dynasty officially sponsored such a continuation for its predecessor, usually compiled by a committee from the records of the fallen dynasty (e.g., the "Veritable Records" of each emperor's reign). These and Ssu-ma Ch'ien's pioneer work make up the 25 standard histories.

The *Draft History of the Ch'ing Dynasty*, completed in 1928, never received official status, but it remains an indispensable source for the period it covers. The others are of similar value, though none deals in detail with events not connected with the court or government. The same applies generally to the independently written histories; *e.g.*, the celebrated *Tzu Chih T'ung Chien* (*Comprehensive Mirror for Aid in Governing*), a general history by Ssu-ma Kuang (1019–86), of which a later abridgment and various continuations formed the basis of the first European history of China. Aside from formal histories, innumerable other texts—biographical, geographical, technological, miscellaneous—can be used with critical care to fill in the background. Modern Chinese historians have produced many books and studies on currently accepted principles, including those of Marxism.

Philosophical Works other than those considered classics are catalogued together with all sorts of polemical and theoretical treatises and include some works of a religious nature but little on Buddhism, which had its own extensive canon outside the four classifications.

Early attempts to persuade men to courses of action (or inaction), by composition in a written language long based on symbols for concrete ideas and relatively simple extensions of them, were important in developing that language into a flexible medium for expository prose.

Persuasion rather than mere conviction was the aim; philosophy in China has been concerned mostly with principles for the guidance of human behaviour rather than with metaphysics or systems of logic. Hence it was usually political or antipolitical. Confucius' time was one of disunion and social breakdown; he preached return to a traditional age of sage kings who were in harmony with the Way of Heaven and governed by example. There were now many rival kingdoms, but Confucius maintained that a true king would receive the voluntary submission of all. A subject could at least become a gentleman (the Chinese term meant a prince's son, but the sage gave it a moral sense) with such virtues as humanity, justice and reciprocal fidelity between parents and children, superiors and inferiors.

Confucius emphasized, as manifestations of these qualities and as disciplines in preserving them, strict observance of time-honoured public and private rituals and manners. These ideas can be pieced together from the laconic *Analects;* they were developed, with certain divergencies, by similarly oriented teachers such as Mencius and Hsün Tzu.

To some other thinkers, the existence of political structures, rules of conduct and reverence for the past meant only that men had deviated from the Way (*Tao*), which could only be followed intuitively and could never be embodied in records or words. Yet these mystical Taoists wrote numerous books themselves. The *Tao Te Ching* (*Scripture of the Way and Its Power*) is one of the most frequently and divergently translated Chinese texts. Its alleged author, Lao Tzu (Lao-tse), was supposed to have lived in the time of Confucius, but at least parts of it are later than some of the *Teachings of Chuang Tzu.*

The latter contains passages of brilliant style and wit. Unlike many later Taoist writings, with their esoteric recipes for direct immortality, it more than once counsels accepting death with equanimity.

Few of these early writings were by a single hand, hence they are not always consistent. Taoism and Confucianism, often in conflict, were not mutually exclusive. Many writers classified under one school show elements of the other. Mo Ti stood apart from either in preaching universal love, a beneficent deity, and interceding spirits, while opposing useless ceremony. The legalists put no faith in good intention or example and called for explicit, rigorous law under absolute totalitarianism. Their program achieved the first unification of China, but the Ch'in dynasty (249–207 B.C.) was short-lived, and Confucianism became orthodox under the succeeding Han.

Scholar-administrators fostered acceptance of a textual canon which would be of higher authority than that of changing rulers, and of which they themselves would be the recognized interpreters. Thereafter Confucianism developed mostly through commentary on fixed texts.

Occasional independent philosophers appeared (*e.g.*, the skeptic Wang Ch'ung and the youthful metaphysician Wang Pi). Taoism in one direction degenerated into magic and became a popular religion, which soon had the powerful competition of imported Buddhism. Confucianism, with its noncommittal position on the supernatural and its emphasis on obligations, remained the official standard, but even emperors often favoured one or the other of its competitors.

Eventually the traditionalist philosophy vitiated its rivals by borrowing from them. Neo-Confucianism, as articulated by Chu Hsi (1130–1200) in a feat of syncretism comparable to that of

St. Thomas Aquinas, remained grounded on the classics but invested them with an eclectic metaphysic and cosmology. Its conservative ethic dominated Chinese mores, as Chu Hsi dominated scholarship, until modern times.

An influential modifier, Wang Yang-ming (1472–1528), gave the pursuit of knowledge a subjective interpretation suggestive of Zen Buddhism. The school of "Han Learning" from the 17th century sought an objective view of history, but its followers confined their investigations largely to textual problems.

At the turn of the 20th century, conditions brought political theory again to the fore. K'ang Yu-wei and, at first, Liang Ch'i-chao tried to rehabilitate Confucianism as a modernized state religion; Sun Yat-sen attempted to combine the western liberal tradition and some elements of Marxism with Chinese concepts. After 1949 the Communist state imposed an orthodoxy more absolute than Confucianism ever enjoyed.

Of professional philosophers, outside the field of action, the best-known Chinese name at mid-century was that of Fung Yu-lan, whose works show in different phases the influence of neo-Confucianism, western neorealism and Taoist transcendental thought.

Collected Works, as a standard classification, include all the poems, essays, letters and occasional pieces by a given man, but not a single drama or novel.

Until the 19th century the professional author, receiving money for publications, was virtually unknown in China. However, nearly all educated men were professional writers, their ability to compose documents being their primary qualification for civil employment.

Anything else they wrote was incidental, but could hardly be called avocational since proficiency in verse and certain other accepted forms was required for the government examinations as well as by social exigency. Actually a talent for literature often had a great deal to do with a man's reputation and consequently with his advancement. Production of less dignified genres, on the contrary, was harmful to an official career and hence usually unacknowledged.

Poetry in China from the beginning made rhyme as important as rhythm. The ancient *Classic of Songs* is a collection of folk songs (polished by court scribes), ceremonial odes and dynastic hymns, all from North China. Later commentators interpreted even the love songs as moral and political allegories. Similar treatment was inflicted on the next-oldest preserved poetry, which originated farther south in the incantations (often erotic) of male and female shamans. These inspired the melancholy rhapsodies associated with the vague figure of Ch'ü Yüan, central among which stands the luxuriant, obscure "Li Sao" ("Falling into Trouble"). Partly from these, in turn, came the rhymeprose (*fu*), with a short prose introduction and strongly rhythmical sections making free use of rhyme. It was characterized by virtuoso piling up of words for cumulative effect, as already in the goddess-haunted "Rhymeprose on Mount Kao-t'ang" attributed to one Sung Yü (third century B.C.?).

Eventually some writers used the *fu* for more formal or more realistic subjects, as Lu Chi (A.D. 261–303) in his brilliant "Rhymeprose on Literature"—the first systematic Chinese essay on literary form and theory—and Yü Hsin (513–581) in his great "Lament for the South" on the fall of the Liang dynasty. But during Han times, when the *fu* was the chief rhythmic vehicle for the literati, it remained predominantly descriptive.

Meanwhile the Han imperial music bureau had started writing down the songs of the people for adaptation to court use. These lyrics and ballads (called *yüeh-fu* poems), more varied in theme and expression than the ancient *Classic of Songs*, gradually inspired literary men to simpler poetry mixing personal sentiments with folk themes.

The Wei dynasty prince Ts'ao Chih (192–232) raised this combination to poetic heights. Even more individual was the recluse T'ao Ch'ien (365–427), one of China's greatest poets. He spent nearly all his life on a small farm close to nature, which permeates his poems both realistically and philosophically. He also took considerable comfort in wine. Coterie poets of this period of disunion were more self-consciously unconventional, often proclaiming their scorn of official life, celebrating wine and fantasy. Others devoted themselves to erotic themes, praising beautiful women in the ornamental palace style, a pastiche of cliché. After the reaction against this preciosity, poets seldom wrote about sexual or romantic passion, at least for circulation.

The T'ang dynasty (618–907) is often called the golden age of Chinese poetry, because it produced galaxies of major and minor poets and because early in this period was crystallized the verse form par excellence. The regulated poem (*lü-shih*) is so considered because it fully yet compactly exploits the tonal resources of the Chinese language. It consists of a stanza of eight five-word or seven-word lines with a complex pattern of tonal or pitch contrasts. In such brief space there is no place for connectives; the style is inevitably elliptical and allusive. Even more concentrated is the stop-short (*chüeh-chü*) containing only four such lines.

Able poets sometimes violated the rules and often wrote freer "old-style" types of verse; no Chinese literary form, once established, was ever abandoned completely.

T'ang poetry reflects the dynastic glory and sophisticated cosmopolitan life of the period but also the hazards of political careers and the hardships of internal war and disaster. One of history's most lavish patrons of the arts was the emperor Ming Huang (Hsüan Tsung), yet his reign was broken by a rebellion which sent his pensioners scurrying about the empire in search of food and shelter. The insouciant Li Po, once a favoured guest at court, in his wanderings continued to write virtuoso fantasies and heightened evocations of landscape with the same ease as before. A legend grew up that he drowned while drunkenly trying to embrace the moon's reflection. Tu Fu, a man of soberer character, a conscientious minor official and a painstaking writer, put into his poems the hardships and sorrows of his own life and those of the common people.

For his broad humanity coupled with meticulous craftsmanship many Chinese consider him their greatest poet. Some of his and Li Po's poems were messages to each other. Meetings and partings of friends is a ubiquitous subject in Chinese poetry, often treated with deep feeling as between these two, perhaps oftener as a social-literary convention.

In later and calmer T'ang times the ballads and lyrics of a gentler poet, Po Chü-i (772–846), made his name a household word. One of the most appealing of Chinese poets, he is also one of the most translatable. More difficult are the poems of his contemporary Han Yü, chiefly known as a model prose writer. He championed a return to the simplicity characteristic of Chinese prose before it accumulated a set of elaborate rules involving verbal parallelism and verselike regularity. As a poet he wrote largely in regulated verse, but brought to it an unhackneyed vocabulary and employed harsh combinations when he wanted a harsh effect.

Equally original, at about the same time, was the short-lived Li Ho, whose strange satanic poems have been compared with those of the French symbolists.

Toward the end of the T'ang a previously subliterary form, the *tz'u*, began to enjoy a measure of artistic status. Young men set their own words to songs they heard in the brothels and teahouses, following the rhythm and melody of a given song so that the resulting love poem was often in uneven lines. Some of the loveliest and saddest are by Li Yü (937–978), second and last ruler of the ephemeral Southern T'ang, who died a prisoner of the Sung.

In the Sung dynasty (960–1279) the *tz'u* was adapted to more varied subjects, and much of the best poetry of the period was in this form, though its origin prevented inclusion in a man's collected works. Sung writers also revitalized the rhymeprose, while making of it less rhyme and more prose; the "prose *fu*" of Ou-yang Hsiu are especially noteworthy. The most popular Sung poet, Su Tung-p'o, reworked as a *tz'u* one of his two famous *fu* about his visits to the Red cliff on the Yangtze. The most prolific of all Chinese poets, Lu Yu, especially wrote patriotic pieces urging defense of Sung China against its encroaching enemies. For several centuries after its fall, the finest verse appeared in opera librettos.

Drama or opera evolved slowly from court ballets, street en-

tertainments and variety shows. The theatre as an integral artistic and popular institution emerged in the Yüan dynasty (1279–1368). For its character and history, *see* DRAMA. Despite or rather because of its great popularity, the drama was not a respected medium for literary talent, partly because the narrative and dialogue parts were written in the language of everyday life. There was little precedent for writing down such language, and doing so could not advance a man's career in an officialdom for which even the entrance examinations were in the terse literary language.

In the Yüan period China was ruled by the Mongols, and the classical examinations counted for little. Apparently some educated Chinese to whom office under the conquerors was either closed or repugnant, having time on their hands, took an interest in the theatre and began to write for it, doubtless not without pay. Verses for the arias more or less remained in the literary language, being made intelligible to the ear through colloquial asides by the performers.

Fiction existed in written form from early times, in the sense of elaborations on history and anecdotes in philosophical writings. Nobody knows how much of the *Intrigues of the Warring States* or the *Tso Commentary* is factual, how much hearsay or invention. Even in later times, hero tales and ghost stories were intended to be taken as true reports. The poet T'ao Ch'ien wrote a famous prose allegory, "The Peach Blossom Source," but not until the T'ang period did the literary tale come into its own. From frequent use of the supernatural such tales were called *ch'uan-ch'i*, "narrations of strange things." Many were love stories. They were still written in the scholar's language, and could scarcely be read by any other class; the masses depended on itinerant storytellers in the streets.

These entertainers seem to have kept simple outlines or prompt books in the vernacular, which printers began to bring out in illustrated popular editions, which fell into the hands of scholars who read them in private and polished them for diversion. They expanded the outlines, adding new incidents and subplots, retaining as chapter endings the storyteller's allurement: "And if you don't know what happened then, listen to the next episode."

Thus the novel was born. For centuries it remained outside the pale of recognized literature, unsigned or attributed to a rival, since discovery might ruin the author's official career. Authorship was often composite, different readers making any alterations or additions they liked; numerous variant editions appeared. The *Romance of the Three Kingdoms*, prototype of many novels based on historical characters and themes, existed in fairly extended form as early as the Yüan period, but the present 120-chapter version probably dates from the 16th century. The *Water Margin* (retitled *All Men Are Brothers* in one translation) deals sympathetically with the exploits of a band of robbers in the 12th century. The *Journey to the West* (partially translated as *Monkey*) by a known author, Wu Ch'eng-en (?1500–80) is a satirical allegory written in the manner of an interminable but amusing fairy tale.

The first novel of everyday life, divorced from legend, history and the street entertainer's conventions, was *Chin P'ing Mei* (completely translated as *The Golden Lotus*), written anonymously in Ming times. Its theme is the ruin caused by selfish pursuit of pleasure; because of its frequent pornography, probably introduced to ensure readers, it has been especially denounced. Yet it is a truly great realistic novel, complex in plot and convincing in characterization.

The 18th-century *Dream of the Red Chamber* (*Hung Lou Meng*) is a sentimental but psychologically penetrating love story developed against the background of a large family and its declining fortunes. Ts'ao Chan left this novel unfinished at his death, and Kao E carried it to a conclusion. The death of one of its two heroines has called forth at least as many tears as Samuel Richardson's *Pamela*, written not much earlier.

Several Ch'ing dynasty novels sharply satirized official corruption and inefficiency. In the last years of the Chinese empire an unsuccessful businessman and reformer, Liu E (1857–1909), wrote the semiautobiographical *Travels of Lao Ts'an*, which has little plot but is unified by an original personality. It reflects his multiform interests, including the Sherlock Holmes stories, but primarily his anxiety over the future of China, represented in a dream by a floundering ship with an irresponsible and vicious crew.

The colloquial short story developed concurrently with the novel, retaining the oral storyteller's clichés to an even greater extent. Stories of exemplary conduct were rather conventional; love stories showed far more realism and invention. Three definitive anthologies published in late Ming times are known collectively as the *San Yen*.

In the Ch'ing dynasty the literary-language tale of ghosts and marvels was revived, with especial artistry in P'u Sung-ling's *Strange Stories from the Liao-chai Studio*.

Women Writers, exceptional in premodern China because of educational and social limitations, were by no means unknown. Pan Ku's sister, Pan Chao, contributed substantially to his *History of the Han Dynasty*. It became a convention for men to write love poetry from a woman's standpoint, reserving the masculine first person for poems of friendship; but countless anonymous love poems are traditionally attributed to various women. Known poetesses include Ts'ai Yen, who wrote 18 memorable stanzas about her long captivity by a border tribe in late Han times; Yü Hsüan-chi, a Taoist nun and mistress of more than one T'ang poet; and Li Ch'ing-chao (Sung dynasty), famous for her *tz'u*. Female professional authors appeared in the 20th century (*e.g.*, leftist short story writer and poetess Ting Ling).

The Literary Revolution which followed the political one of 1911 virtually abolished the terse traditional style; the mainstream of literature shifted to an approximation of the vernacular. This change, championed in 1917 by Hu Shih and Ch'en Tu-hsiu amid a storm of controversy, came about largely for practical rather than purely literary reasons.

A modern China must aim at nation-wide literacy, impossible if education should remain divorced from speech patterns, and at assimilation of the theoretical and practical knowledge of the rest of the world. Even in the new *pai-hua* (plain speech) style, officially taught in the schools after 1920, new terms had to be coined, eventually becoming idiomatic.

Authors freely borrowed both ideas and techniques from Europe and America, where some of them studied. Western literary trends reflected in China generally were those of several decades past: Ts'ao Yü's play *Thunder and Rain* shows the influence of Ibsen, Mao Tun's novel *Midnight* that of Zola and Tolstoy. Although the high place occupied in European literature by fiction and drama had much to do with the reappraisal of China's own popular literature, the traditions of that literature (other than its use of the vernacular) were more honoured than imitated. The new writings were nearly always bound up with some aesthetic or political program, their authors associating themselves with magazines or manifestoes. Groups dissolved and shifted overnight as iconoclasts became conservatives and aesthetes turned reformers.

Caught between opposing political forces some turned from programs to scholarship, while the most active writers tended more and more to the left. Lu Hsün (1881–1936), whose brief but bitter *Ah Q* is the classic of modern Chinese fiction, was forced into the extreme camp by circumstance rather than by firm conviction, though the Communists later made his works "revolutionary" classics. At mid-20th century the outstanding literary name in Communist China was that of Kuo Mo-jo, an archaeologist, playwright, poet and critic who attained high office as a sort of cultural commissar.

Cut off from the mainland, Nationalist Chinese writers abroad and on the island stronghold of Formosa found it hard to produce creative works rooted in their native soil, but not being bound by an all-pervasive authority they could maintain a higher level of objective literary criticism and scholarship.

Modern Chinese poetry threw off restrictions of form and content, but merely exchanged Chinese models for foreign ones, principally the imagists and Whitman in reverse chronological order. Traditional forms were not completely abandoned—even Communist leader Mao Tse-tung wrote *tz'u* verses—but no general revitalization of them appeared imminent.

Chinese literature obviously would remain in transition until the nation became sufficiently unified and stabilized to achieve again a homogeneous culture of its own. Whether the novels, plays and poems of the future would be anything like those of the past would depend on whether native traditions were to be reassimilated and transformed.

The Communists undertook to reinterpret the whole of China's past literature, for instance revising the still popular traditional plays to emphasize social and economic contrasts in them. But no very individual creative artistry could operate in either traditional or new mediums as long as both were to be rigorously controlled. Meantime contemporary Chinese literature continued to share one important characteristic with that of the past, namely its predominantly didactic nature.

CHINESE MUSIC. Music played a great part in the origins of ancient Chinese civilization. The pitch pipe of the normal pitch (called *huang-chung*) was the basis of the Chinese system of measures, of the calendar and of their astronomical calculations.

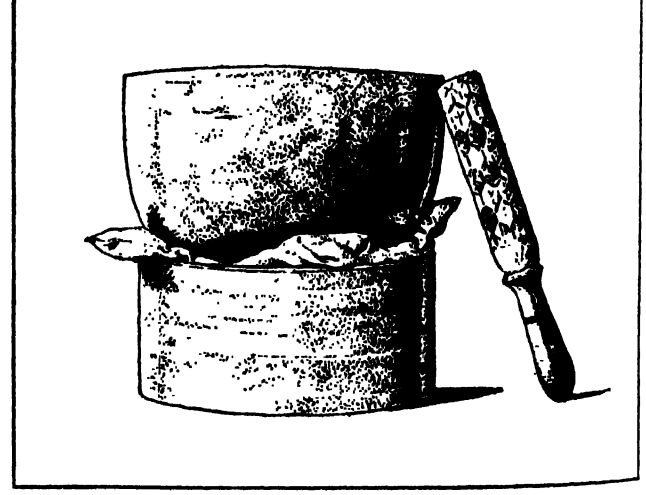
A Musical System.—According to tradition, the emperor Huang Ti (*c.* 2697 B.C.) sent his minister Ling-lun to the Kuen-lun mountains in northwest China to cut a pitch pipe from a species of bamboo which gave the note *huang-chung*. Eleven other notes were derived from this note by the following process: a third part of the nine-inch pipe *huang-chung* was cut off, thus producing a second pipe, *lin-chung*, which was six inches long ($9\times\frac{2}{3}$) and gave the fifth. The second pipe was divided into three parts, and one of the third parts was added to it (8 in. or $6\times\frac{1}{3}$); this gave the descending fourth (*tai-tsu*) from the second pipe, and so on.

This was the origin of the 12 Chinese pitch pipes: *huang-chung* (Ć), *ta-lu* (Ć#), *tai-tsu* (D́), *chia-chung* (D́#), *ku-hsi* (É), *chung-lu* (F́), *jui-pin* (F́#), *lin-chung* (Ĝ), *i-tse* (Ĝ#), *nan-lu* (Á), *wu-i* (Á#), and *ying-chung* (B́). The Chinese system of fifths is first mentioned in the work *Lu-Tsu-Chun-Chiu,* which dates from the 3rd century B.C.—about the time when the Pythagorean musical system was made known in Greece by the pupils of Pythagoras.

As the circle of fifths could not be closed because of the (Pythagorean) comma, the Chinese made a number of attempts in the course of the ages to divide the octave into 60 notes (King-fang, *c.* 40 B.C.), 360 notes (Chien-lo-chih, *c.* A.D. 430), 18 notes (Tsai-yuan-ting, *c.* A.D. 1180) and 12 notes (Ho-cheng-tien, *c.* A.D. 420 and Wang-po, *c.* A.D. 958), equal and unequal temperament respectively. The old system of fifths still continued however to be the prevailing system.

Finally, Prince Chu-tsai-yu, in 1595, a century earlier than Andreas Werkmeister (1691) in Europe, fixed the 12 pitch pipes in equal temperament; in order to obtain the nearest semitone he divided the length of a pitch pipe by 1.0594631 or $\sqrt[12]{2}$ and its diameter by 1.0292857 or $\sqrt[24]{2}$. The mathematical and physical basis was confirmed by experiment by the Belgian authority on acoustics, V. C. Mahillon.

The ancient Chinese scale has five tones: *kung* (C), *shang* (D), *chiao* (E), *chih* (G) and *yu* (A). Later, under the Chou dynasty (1122–255 B.C.), two further notes, *pien-chih* (F#) and *pien-kung* (B), were added.



Each note of this scale of five or seven notes can be used as the primary note of a scale, and this gives five or seven modes, just as in Greek music there are the Doric mode, the Phrygian, etc. As each of these five or seven modes can be transposed in 12 ways, there are 60 or 84 keys in Chinese music. (X.)

Musical Practice.—The ancient theory and the classical music of past centuries were connected almost exclusively with the rites and ceremonies of the temples of worship and of the court. One of the old literary classics, the *Li Chi* or *Book of Rites,* contains many allusions to music; and one whole section (said to be a later interpolation) is devoted wholly to music in its ethical, ritual and symbolic aspects. The imperial ministry of rites once included a bureau of music, but the function of that office seems to have been entirely a matter of ceremonial tradition and to have had no connection with the practice of music in its popular forms. The performance of ritual music was continued in certain places up to recent times with a scrupulous adherence to tradition. The solemn celebration of the highest office of the Confucian worship is accompanied by a traditional orchestra of 44 pieces. Taoist temples are content with about six instruments. In the Confucian solemn rite the emperor himself was supposed to be the chief celebrant.

The pentatonic, nonharmonic music for this celebration has often been reproduced in European notation in the books on Chinese music, particularly the solemn march to which the imperial worshipper proceeded to the door of the temple and the concluding monodic hymn to Confucius (*Ta tsai K'ung tsen*) in which all the instruments and voices took part.

Music outside the temples is more popular in character and has probably been subjected to more frequent changes in style; although even here the tenacious conservative instincts of the Chinese handed down a more archaic type of music to the present day than is known in the occidental countries. The practice of this music by individuals, particularly by amateurs of high social status, for their own aesthetic satisfaction is not so widespread in China as in the west.

Home or household music seems to have been more highly developed in Japan than in China. There is, in China, no well-organized class of professional music teachers. Most musicians acquire their art in a purely empirical way, although there is a

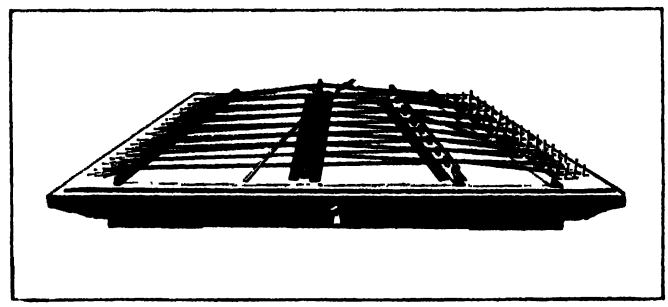
CHINESE GONG AND STICK. A MUSICAL PERCUSSION INSTRUMENT NOW USED CHIEFLY IN THE THEATRE

considerable body of books containing the notations of tunes for various instruments. This notation is not a staff notation, but a tablature system; that is, a series of signs or symbols for the individual tones, frets or finger positions.

Vocal music has an important place in the temples and still more in the theatre. Apart from this it is not cultivated as an art co-ordinate with instrumental music to the same extent as in western nations, although the singing of songs and ballads is not uncommon.

Musical Instruments.—The number of instruments used by



the Chinese is comparatively large. Moule lists and describes not fewer than 130. Many of them are, to be sure, mere toys or signal instruments of no great musical importance. They are used by mountebanks at fairs or markets, and by hawkers or beggars. European writers about Chinese instruments devote much space to the description of the ancient classic instruments used in temple worship, many of which have long since gone out of common use. They are largely percussion instruments, including many forms of highly ornamented drums (*Ying ku*, 應鼓; *po fu*, 搏拊; *pang ku*, 梆鼓), sonorous stones single (*t'e k'ing* 特磬) or arranged in chimes (*pien k'in* 編磬) or bronze bells used in the same manner (*po chung* 鎛鍾; *pien chung* 編鍾). The *k'in* 琴 is a narrow hollow box 3 to 4 ft. in length, with slightly convex upper surface. It has five, or in more modern instruments, seven silk strings plucked with the fingers, and was still used until fairly recent times for refined artistic music. Its Japanese counterpart is the *koto*. A larger instrument constructed on the same principle, but having in earlier times as many as 50 strings, later only about 25, is the *se*, rarely used except in ceremonies. The ancient instruments were classified by the older theory according as they produced the sound of stone, metal, silk, bamboo, wood, skin, gourd and earth. The most important instruments still in use are the two-stringed fiddle, *hu k'in*, 胡琴; the four-stringed moon guitar, *yueh k'in*, 月琴; the four-stringed, pear-shaped, balloon guitar, *p'i p'a*, 琵琶; the three-stringed guitar with a very long neck, *san hsien*, 三絃; a first cousin of the Japanese *samisen*. Of the flute type are the straight (direct) flute *hsiao* 簫; and the transverse flute *ti*, 笛. Reed instruments are represented by the gentle *kuan tzu* 管子, a straight bamboo tube, 8 to 10 in. long, with a rice straw serving as a double reed or oboe mouthpiece; and the shrill, *so na* 鎖吶, a double reed instrument with a conical wooden body ending in a metal "bell," often called the Chinese clarinet. The *sheng* 笙 consists of a lacquered wooden body (formerly a gourd or calabash), about the shape and size of a tea cup, and a mouthpiece through which the player inhales the air. On the body are grouped 13 to 17 speaking pipes, slender bamboo tubes each provided with a thin, free reed of metal. Each tube has a hole below the reed and the pipe speaks only when the hole is stopped by the player's finger. The *yang k'in*, 洋琴, or foreign psaltery, consists of a trapezoidal sound box about 2 ft. in width over which are usually stretched 14 to 20 double, triple or quadruple sets of metal strings which are played by striking them with two light bamboo rods.

OF ART

THE THREE-STRINGED CHINESE BANJO, SHOWING LONG NECK

Modern percussion instruments, used chiefly in the theatre, include the large gong (*lo* 鑼), cymbals (*po* 鈸), a flat circular drum, struck with a pair of light sticks (*pang ku* 梆鼓) and sharply resonant wooden blocks or castanets (*pe pan* 拍板). Before the revolution of 1911–12, professional musicians had no high social standing. Those who played in the theatre commanded more respect than the players in funeral or wedding processions. Courtesans and beggars who played and sang, and ballad singers were of the lowest rank. The Chinese theatre makes copious use of music, the drama being practically a music drama. A relatively very small part of the play is given over to unaccompanied spoken dialogue. The recitative portions are either punctuated by the percussion instruments or are invested with a continuous rhythmic accompaniment of these instruments which often drown out the actor-singer's voice. The lyric portions of the performance are accompanied by the fiddles, guitars, flutes or pipes. The protagonist selects the tunes from among a large number of well-known conventional strains or motives, said to be very old. The instrumentalists accompany in unison, although, since they play without written music, embellishments and variations are produced *ad libitum*, and there are at times instances of the use of double notes and traces of an embryo type of contrapuntal invention. The Chinese ideal of good vocal performance, particularly for the male actors, requires a high, forced falsetto tone production.

CHINESE DULCIMER (YANG CH'IN), HAVING 16 SETS OF STRINGS, 4 IN EACH SET, AND PLAYED WITH TWO BAMBOO BEATERS

All of this music, as well as the popular music of funeral and wedding processions and of street songs is, like the sacred music, distinctly pentatonic. But where, as in the popular orchestra or solo performance, the art of improvisation and embellishment has free play, the larger intervals of the five-tone scale are frequently filled out in runs and figures, as a careful analysis of phonograph records (Erich Fischer) has shown. But even here the importance of the pentatonic skeleton or foundation is beyond doubt and is easily sensed by the European hearer. Since the revolution the influence of Western music has become more marked.

CHINESE PAINTING. The first thing to be said about Chinese painting is that very little is known of its actual achievements. We have indeed ample records of the lives and works of innumerable painters, from the first centuries of our era onwards, and a mass of criticism. Chinese paintings also exist in vast quantities. But it must be realized that of genuine, or probably genuine, works of the great masters of the best periods, very few indeed remain. It is impossible to doubt, from the evidence of what has survived, and from literary records, that Chinese painting, with its majestic and continuous tradition of more than 1,500 years, is one of the greatest schools of painting that the world has seen. But we are quite without the means of comparing Chinese painting as a whole with the paintings of Italy, or any other European school, the successive masterpieces of which are known and accessible to every student.

It is true that during the 20th century the almost complete ignorance which prevailed on the subject till the end of the 19th century has been greatly lessened. Important discoveries have been made, and it is impossible to predict what may yet be discovered. The fundamental difficulties, however, of the study of Chinese painting are likely to remain; the extreme rarity, namely, of certain and documented works, on which an accurate conception of the greater masters' style can be based. The practice of repeating famous designs with variations, of copying ancient works, which has prevailed in all ages, makes it possible to have a general idea of the styles of certain periods and certain masters.

But immense and repeated destruction accounts for the rarity of ancient pictures in China itself. In Japan collections have been made, centuries ago, and religiously preserved; and these paintings form the best foundation for study, though in many cases the traditional attributions have been abandoned by modern criticism.

General Characteristics.—Painting is the pre-eminent art of China. It is right that the art of any nation should be judged by a world standard, not merely from a national point of view. In spite of all differences and peculiarities, Chinese painting takes its place with the other pictorial arts of the world, for there is a fundamental affinity between all successful works of art.

Painting, for the Chinese, is a branch of handwriting. Both for writing and painting a brush is used; and to acquire a fine hand in writing demands a mastery in manipulating the brush and modulating its strokes such as few European painters attain. Ink is the favourite medium; but Chinese ink is a wonderful substance, capable of an immense range and an extraordinary beauty of tone. Many Chinese masterpieces are in monochrome. Coloured paintings are either light-coloured or full-coloured; but the ink-drawing remains almost always the foundation of the design. Fresco-painting, technically a different method from the fresco-painting of Europe (*see* Church's *Chemistry of Paints and Painting*, p. 307, 1915), was largely practised—and probably the grandest art of China was in this form—but the frescoes of the finest period seem all to have been destroyed. The great mass of Chinese pictures, however, are paintings on silk or, less commonly, absorbent paper, the pigments being water-colours or body-colours (*see* R. Petrucci, *Encyclopédie de la Peinture Chinoise*, 1918, a translation of a well-known treatise illustrated with woodcuts called the *Mustard Seed Garden*. *See* also Ferguson's *Chinese Painting*). Paintings are usually in the form of hanging pictures or of horizontal scrolls, in both cases normally kept rolled up. The latter form involves a mode of composition peculiar to Chinese art, though imitated by the Japanese. These paintings, often of great length, are unrolled bit by bit and enjoyed as a reader enjoys reading a manuscript. A succession of pictures is presented, though the composition is continuous. Thus, in the case of landscape, for which this form has been used with most felicity, one seems to be actually passing through the country depicted. Other forms are the framed picture and the small album picture; screens also were employed for painting.

Chinese technique admits of no correction. The artist closely observes and stores his observations in his memory. He conceives his design, and having completed the mental image of what he intends to paint, he transfers it swiftly and with sure strokes to the silk. The communication through the sensitive and powerful strokes of the brush of something personal and unique must, in such an art, count for much in the spectator's appreciation. The qualities prized by the Chinese in a small ink-painting of bamboos, a favourite subject alike with beginners and masters, are those prized in a piece of fine handwriting, only there is added a keen appreciation of the simultaneous seizure of life and natural character in the subject. In the *Mustard Seed Garden* treatise cited above, it is said that in a master's work "the idea is present even where the brush has not passed." And this emphasis on the value of suggestion, of reserves and silences, is important to notice, because no other art has understood, like the Chinese, how to make empty space a potent factor in the design. It may be that Chinese painting relies too much on suggestion, presuming in the spectator a sensibility and a fineness of organization which are found but in choice societies; on the other hand it avoids that laborious accumulation of unessential phenomena which in European art has proved the death of so many pictures by accomplished hands. A certain slightness, comparatively speaking, is inevitable in Chinese paintings, partly because of the water-colour medium, partly because suggestion is preferred to statement, partly because so many of the artists were amateurs and not professionals. It is remarkable, however, how solid and structural a Chinese landscape can be. The greater painters gave much thought and pains to elaborating a convention by which the sense of shape and mass can be given to rock forms, for instance, without losing directness and vitality of brush stroke, the sense of handwriting. Each successful convention was preserved, handed down and imitated. Mountains could be painted in the manner of this old master or of that. And the Chinese, with their passion for codification, have carefully tabulated all these various methods. The painter's art is also saturated with literary associations. Certain flowers and certain birds, for instance, are painted together because their association is consecrated by a classic poem. Many of the painters were poets; some, like Wang Wei, equally distinguished in both arts. But it is less the direct illustration of a poem or story that is normally aimed at, than the evocation of a mood similar to that expressed in the poem.

When we turn to the subject-matter of Chinese painting, we are struck by the early appearance of landscape art and its actual predominance. Landscape is accounted the most important of subjects because it includes man and all living things; the whole is greater than the part. Man does not play the central and heroic part that he plays in the art of Europe, for which the nude human form is the most significant and expressive of motives. Flowers are quite as important as figures. This difference in the fundamental conception of life and the universe makes itself felt in design. Instead of the symmetry which contemplation of the human body has made the basis of Western composition the Chinese prefer the principle of balance. They contemplated trees and saw that they were unsymmetrical but perfectly poised. Where in Europe we have Christian themes, in China we have Buddhist themes; instead of the stories of classic mythology we have the stories of Taoist legend and the fairy tale. Genre-painting (*q.v.*) is as common as in the West, though portraiture is perhaps less common. But always the life of the world outside man,—the life of animals, birds and plants—plays a much larger part than in Western art. The life of action counts for less, and the contemplative life for more.

HISTORY

Early Periods.—From literary references we can infer that painting was practised in China several centuries at least before Christ, chiefly in the form of portraiture. It is not till we come to the Han dynasty, that we have any more tangible evidence, though there exist some rude designs in red on jade which may be a thousand years earlier. Designs on lacquer of the 1st century A.D., found in Korea by Mr. Umehara, and in Chinese Turkistan by Sir Aurel Stein; some rough paintings on tiles (Eumorfopoulos collection), and other decorations; outline drawings on vases of rather later date, give some hint of what painting in the Han period was like. We see that a Chinese type of decorative design, animated by movement in the forms, was already matured. The incised stone friezes of the period are clearly translations of paintings, and these give an idea of the character of pictorial design and the range of subject—scenes from history and legend, ceremonies, dances, mythical creatures, and all the fairy world of Taoism.

In the 4th century, however, flourished an artist who ranks among China's most famous masters: Ku K'ai-chih. There exist two rolls attributed to him: one, *The Admonitions of the Instructress in the Palace*, is in the British Museum; the other, illustrating a poem on a river nymph, is in the Freer collection at Washington. These paintings are by different hands. The one in the Freer collection is altogether drier in handling, and may be a Sung copy. The British Museum roll is of a marvellous subtlety and distinction; the line is intimately expressive. Its actual date is disputed, but it is generally thought to be, if not an original, a T'ang copy. In any case there is no doubt that both of these paintings represent the design of the Chin dynasty (A.D. 265–420). They are, therefore, extremely precious documents, and their value is increased by the fact that while the British Museum roll depicts scenes of court life, with all the details of dress and accessories of singular refinement, the Freer roll, with its dragon chariot and floating fairies, gives the imaginative or fanciful side of the art of the period. In both cases the landscape element is quite primitive. The landscape introduced into the London painting is indeed in strong contrast with the consummate grace and expressiveness of the tall and slender figures,

and the air of a mature and fine civilization which they seem to breathe. Far from being primitive, the figure-drawing seems to belong to the close of a tradition rather than its beginning; and we may conjecture behind it the ruder, masculine style of Han gradually subtilized and transformed in the direction of elegance and charm. Ku K'ai-chih famed especially for his portraits, painted all kinds of subjects, including Buddhist themes. But if we may take these two pictures attributed to him as typical of the period, we find no trace of Indian influence in them.

Of about the 6th century are some of the earliest wall paintings in the rock temples at Tun-huang, on China's western frontier (see Pelliot, *Grottes de Touen-houang*, vol. iv.), full of animated movement, containing figures of the same slender and elegant type as those in the Ku K'ai-chih roll. But these are provincial in manner.

It was in the 6th century that the famous six canons of Hsieh Ho himself a painter, were formulated. The exact meaning of the first and most important of these has been disputed, but it is clear that the emphasis is laid on creative inspiration, conceived not as a personal gift, but as the spirit of the cosmos entering into the artist and enabling him to produce in his forms the movement of life.

The legends of the great masters tell, not of the deceptive appearance of reality in their paintings, but of their being so informed with passionate life that they assumed material existence and motion. The emphasis on movement is significant. Even in decorative designs the forms seem to move and flow.

The T'ang Dynasty (A.D. 618–907).—In the 7th century the empire, after a period of division, was consolidated under the great T'ang dynasty, which lasted for 300 years. This was undoubtedly the period of China's grandest art. It is true that almost all the painting of the time has perished; but all the available evidence confirms the testimony of the Chinese historians and critics to the greatness of the T'ang masters. Some fragments of a painting of a spring festival, found by Sir Aurel Stein in 1914 at Turfan, and some other paintings found in the same locality by the Otani expedition, are precious relics of early T'ang art, for they show us something of the pictorial style of the early 8th century. Here we find the new T'ang ideal of feminine beauty: a more massive form, compared with the slender elegance of preceding periods; a full, rounded face, with hair heaped around and above the head, and an air of smiling health. Precisely the same types and the same pictorial motives are found in the few pictures surviving from this period in Japan. And it is from the early painting of Japan, closely modelled on Chinese prototypes, that we can most safely infer the great style of T'ang. This kind of painting is mostly Buddhistic, and the grandest T'ang works were of Buddhist inspiration. Supreme among them, according to all testimony, were the works of Wu Tao-tzŭ, acknowledged to be the greatest of all Chinese painters.

China, during this epoch, was open to foreign influences as she has never been since. Her empire expanded westward; her suzerainty extended as far as the Caspian. Envoys and tribute-bearers were constantly coming or going; there was a great interest in foreign ways, dresses and customs; Indians, Persians, Turks and Syrians met in the capital, which was truly a world centre. But the influence of greatest moment was Buddhism, now accepted with fervour. Great numbers of Indian monks, some of them doubtless artists, were settled in China. Chinese pilgrims journeyed to India and brought back sacred manuscripts and images. But Chinese art, strong in its own traditions, was able to assimilate the Indian formulae and create a Buddhist art of extraordinary splendour. Among the earliest of the T'ang masters may be mentioned Wei-ch'ih I-sēng, who came from Khotan to China about 630. A copy of a picture of Vaisravana by this artist is in the Freer collection at Washington; and his style is perhaps to be discerned in a remarkable roll in Mr. Berenson's collection. Yen Li-pēn (born *c.* 600), was famous for his portraits of national worthies, foreign envoys and Buddhist pictures. We know his work only through copies. With Wu Tao-tzŭ, T'ang painting underwent a transformation. His early style was fine and delicate; later, it became broad and of amazing power. He painted over 300 Buddhist frescoes, as well as paintings of all kinds of subjects on silk. All have perished. One or two of his designs have been preserved by being engraved on stone, and some paintings and drawings are extant which may be copies from his work. The majestic fresco *Three Bodhisattvas*, given to the British Museum by Mr. Eumorfopoulos, dating probably from the 12th century, presumably preserves the T'ang tradition, and from it we may infer the yet grander and more magnificent creations of Wu Tao-tzŭ and his followers. All records agree in emphasizing the overwhelming power of his creations and also the almost sculptural character of his figures. Of actual and authenticated work by a known T'ang artist we have only five portraits of priests (much damaged) painted about 800 by Li Chēn and preserved in Japan. These are in a contained and rather austere style. But our chief documents for T'ang Buddhist painting are the pictures recovered from Tun-huang, on the western frontier of China, by Sir Aurel Stein and Prof. Pelliot. These are now in the British Museum, at Delhi and in Paris. A certain number are dated, with dates of the 9th and 10th centuries. Those which are in Chinese style may be taken to reflect the central tradition of Buddhist painting, though in a more or less provincial form. Of much the same character is a large Buddhist picture of the 9th century in the Boston Museum.

The Tun-huang pictures are largely devoted to the cult of Amitabha Buddha, who presides over the Western Paradise, and of his spiritual son Avalokitesvara, or Kuan-yin, the genius of Compassion, who in later times assumes a feminine form. There are many pictures of the Paradise, in which we see a host of blessed beings presided over by a Buddha (usually, but not always, Amitabha) gathered round a sacred concert, where a dancer performs to music on a terrace raised above the lotus-lake. Some of these complex compositions, containing a great number of figures, are remarkable for the harmonious serenity of the design —there is no confusion or awkwardness in the arrangement—and the varied beauty of the colouring. Other votive pictures portray the great Bodhisattvas, especially Kuan-yin, or scenes from the Buddha legend. In the former case, the forms, draperies and ornaments are closely modelled on Indian prototypes; in the latter, types, dress and architecture are purely Chinese. From the small scenes sometimes painted at the sides of the large pictures we get a hint of the secular style of the period both in figure and landscape. The figures of donors, which are also fairly frequent, give us contemporary costume. Though mostly the work of artisans rather than artists, the value of these paintings as documents is very great, and a few are of real beauty as works of art.

In this era landscape became important as an independent art. The character of Chinese landscape is seen in the word for landscape, *shan-sui* (山水), mountain and water. Li Ssŭ-hsün (b. 651) was the first eminent painter who devoted himself mainly to landscape. He painted in greens and blues, with gold outline. None of his works exist, but copies preserve the characteristics of his style. His son, Li Chao-tao, developed this technique. A small picture in the Boston Museum, ascribed to him but probably of later date, gives a good idea of this "miniature" kind of landscape-painting. A very different tradition in landscape was founded by Wang Wei (b. 699), who was equally famous as a poet. He matured a style of ink-painting, in which the landscape became the counterpart of an emotion, more subjective and more "impressionist" in method than the work of Li Ssŭ-hsün and his school. Copies exist (one is in the British Museum, and an earlier one in the Freer collection) of a famous roll by Wang Wei, *Scenery of the Wang Ch'uan*. The painting was engraved on stone when it began to decay. Rubbings have been published by Dr. B. Laufer in *Ostasiatische Zeitschrift* (April 1912).

Ts'ao Pa and his greater pupil, Han Kan, were especially famous for their paintings of horses. Han Kan found endless subjects in the fine horses sent as tribute from Central Asia. He worked in the 8th century for the emperor Ming Huang. A contemporary, Han Huang, painted buffaloes and rustic scenes. The splendidly modelled pottery figures of horses and camels found in T'ang tombs give us a clue to the vigour and breadth

of the animal painting of these masters, whose original work has perished.

Admirable *genre* pictures and scenes from court life were also painted in this era. Chou Fang is known by versions (one in China and one in a New York private collection) of his *Listeners to Music*, a design in which the Chinese genius for eloquent spacing is conspicuous. The beautiful picture in the Boston museum of *Ladies Beating and Preparing Silk* probably preserves a T'ang design.

The Five Dynasties (A.D. 907–960).—In this short period a great many artists are recorded, of whom Hsü Hsi was famous as a flower-painter and Chou Wēn-chü for his pictures of women. Still more celebrated was Huang Ch'uan, who painted landscape, birds, flowers, etc., and who is said to have started what is called the "boneless method"; *i.e.*, painting without a drawn outline.

The Sung Period (A.D. 960–1279).—Under the emperors of the Sung dynasty China was re-united. The emperor Hui Tsung was himself a painter and a great collector. In his reign the Academy of Painting became very prominent and attracted artists from all parts. A certain realism was inculcated, but in style a fastidious simplicity was to be aimed at. The small album-painting of a bird in a bough in the Eumorfopoulos collection, and similar paintings in famous albums in Japan, some of which are attributed to Hui Tsung, illustrate the ideals of the time. Flower-painting, hardly existent in the T'ang period, was now a favourite theme, and some painters, like Wēn T'ung, specialized in ink-painting of the bamboo. Of the flower-painters Chao Ch'ang was the most celebrated. The most eminent master in landscape of Northern Sung was Kuo Hsi, who wrote an essay on landscape, partly translated by Waley (*Chinese Painting*, pp. 189–194). Mi Fei invented a new style in landscape, without outline and with boldly brushed-in wooded peaks rising above rain and mist. His style is preserved in many pictures, though again few or none are likely to be actually by his hand. Chao Ta-nien painted autumn and winter scenes; Fan K'uan was famous for his snow-scenes.

But the most famous name in the art of Northern Sung is Li Lung-mien (*c.* 1040–1106). Much of his work consisted of copies from earlier masters. He had a reverential passion for tradition. At first he painted horses, but soon abandoned such subjects for Buddhist themes. Rarely using colour, he drew with a delicate, nervous line. Copies of his works are numerous, and a few originals have been reproduced in the *Kokka*. He is revered by the Chinese as a perfect type of Chinese culture; judged purely as an artist, he would not have so great a fame.

In 1127 the Tatars occupied northern China. The emperor Hui Tsung was taken prisoner and died in exile. Hang-chow became the new capital of what is known as Southern Sung. The changed temper of the times is reflected in the art of a people no longer greatly interested in external events which they were helpless to transform. The passion for romantic solitudes, for soaring peaks and plunging torrents, which had always haunted certain minds, eager to escape from the pressure of official life and ceremonious routine, became a mastering inspiration. The Zen sect of Buddhism, now dominant, with its reliance on intuition, its contempt for all outward forms, replaced the votive picture of single or assembled Bodhisattvas, glowing with colour and gold, by pictures of Arhats in intense contemplation, or by swift ink-sketches of Zen saints; even a poising bird or blossoming spray could become in this mode of thought as "religious" a theme as the glorified Buddha. The emphasis was all on the interior mind. This temper, to which Taoist love of freedom and fluidity contributed much, gives a peculiar poetic character to the art of Southern Sung. Some there were, like Li Sung-nien, who kept to the older traditions and painted scenes from history and legend, and sets of pictures on weaving and agriculture. But the genius of the age is seen rather in Li T'ang (to whom are attributed a roll in a Japanese collection and a beautiful small picture in the Boston Museum), and still more in his famous pupils, Hsia Kuei and Ma Yüan. Owing to the enthusiasm with which the landscapes of this school were collected in Japan, we are able to judge of its productions from concrete examples. Though this school soon fell out of favour in China, it represents to Europe Chinese landscape at its finest; synthetic in conception, impassioned in execution, it unites simplicity with grandeur. Hills and high places had always been regarded with reverence as the abode of spirits. We find no counterpart to the feeling of aversion or disgust which the Alps inspired in Europeans down to so late a period. And though the Chinese have always been an agricultural people, it is not the relation of toiling man to the fruitful earth which inspires their typical landscape art. It is a more cosmic inspiration; a feeling of affinity between the human spirit and the energies of the elements,—the winds, the mists, the soaring peaks, the plunging torrents. Technically, Chinese landscape design differs from European. The high horizon precludes the need for uniting sky and ground, divided by the natural horizon of sight, by means of vertical lines and masses. The eye passes from the foreground, so often a source of trial and difficulty to the European painter, to the central motive of the picture, usually a mountain form.

The Yüan or Mongol Period (A.D. 1279–1368).—In this comparatively short period there was a tendency to go back to the style of ancient masters. Chao Mêng-fu is perhaps the most famous painter of the time. Countless pictures of horses now in Western collections are attributed to him, few of them with any probability. He also painted landscapes and flowers. Another fine painter was Jên Jên-fa, of whom there is a good example in the Eumorfopoulos collection, and others in Japan. The four chief landscape masters were: Huang Kung-wang, Wang Mêng, Ni Tsan, and Wu Chên. The two latter led roaming lives and had nothing of the professional about them. Ni Tsan painted suggestions of landscape in ink, in a reticent, delicate manner. Wu Chên, known as the "Priest of the Plum-blossom," excelled in paintings of bamboos. Ch'ien Hsüan is a master whose name is very frequently forged on paintings; he painted birds, flowers, also figures. Wang Yo-shui was famous for flowers. Yen Hui is greatly admired in Japan for his pictures of Taoist sages, but is less known in China.

The Ming Dynasty (A.D. 1368–1644).—The art of the Ming period is characterized as a whole by a gradual fading out of the interior glow which under Buddhist and Taoist inspiration had suffused the creations of earlier periods. Concentrated in herself, China had no longer any stimulating contact with the world without; and her art became concerned rather with the beauty of material things than with the expression of the interior spirit. At the same time a reverential conservatism prescribed for the painter both subject and manner of treatment. The painters of this period are so numerous that only a few outstanding masters can be mentioned. The first Ming emperor re-established the Academy of Painting, with the aim of emulating the glories of Sung art. Gifted painters flocked to his court. Lin Liang painted ink-pictures of eagles, wild geese, flowers, etc., in a style of extraordinary breadth and power. A good example is in the British Museum, which also has a fine *Fairy and Phoenix* ascribed to Wu Wei, a master who strove to recapture something of the strong brush-work of Wu Tao-tzŭ. Very typical of early Ming art are the bird and flower pictures of Pien Ching-chao (Pien Wēn-chin) and of Lü Chi, in which a certain solidity and a decorative richness of colour combine with powerful drawing in a large design. In landscape, Tai Chin, accounted one of the foremost Ming painters, led a new movement and had many followers. His style was broad and free, with little or no colour. Another school preferred minuteness of detail, with an ornamental use of colour, especially a rich blue. Of this school were Chou Ch'ēn and T'ang Yin, who also excelled in figures.

Tung Ch'i-ch'ang (1554–1636), eminent as a critic as well as a painter and calligrapher, despised these "professionals" and their laborious technique. He is associated with the "Learned Man's Painting," in which refined taste and literary associations counted for much more than mere accomplishment. Tung Ch'i-ch'ang claimed that this style originated with Wang Wei in the 8th century, the founder of the Southern school. (In distinguishing the Northern and Southern schools, he tried to give these rather shadowy terms a geographical foundation which does not really

exist.) The Southern school, adorned in the earlier part of this period by Shên Chou and Wên Chêng-ming, two much-admired masters, had by the close of the dynasty become triumphant and supreme. Among bird and flower painters of the 16th century, Chou Chih-mien may be mentioned as one of the most distinguished, though his work is rare.

The Ch'ing (Manchu) Dynasty (A.D. 1644–1911).—Painting in the 17th and 18th centuries is very largely devoted to landscape in the style of the Southern school, which in the later developments of the literary man's style becomes loose, slight, capricious and eccentric. Among gifted amateurs of the beginning of the dynasty, Chu Ta is much admired for his ink-sketches of flowers, rocks, etc. More important artists of the K'ang Hsi period are "the four Wangs, Wang Shih-min, Wang Chien, Wang Hui and Wang Yuan-ch'i.

Another great figure in the 17th century is Yün Shou-p'ing, also called Nan-t'ien, the most famous flower painter of the Ch'ing period. Wu Li, who was converted to Christianity and became known as Father Acunha, painted landscapes. The influence of the Jesuits was considerable for a time in China, but had no lasting effect on the arts. The Jesuit Giuseppe Castiglione was made to learn the Chinese style of painting under the name Lang Shih-ning. Chiao Ping-chêng, however, learnt something of European perspective and taught it to Lêng Mei and other artists. Chiao Ping-chêng's sets of pictures of agriculture and weaving were engraved in 1696. Shên Nan-pin went to Japan and stayed at Nagasaki (1731–33); his work had a very stimulating effect on the naturalistic movement in Japan. Apart from this naturalistic movement, the modern painting of China seems to show little new life, and though good painters flourished in the 19th century, they were mostly content with exercises in the various manners consecrated by the past.

CHINESE PAVILION, Turkish Crescent, Turkish Jingle, or Jingling Johnny, an instrument consisting of a pole about 6ft. high terminating in a conical metal cap or pavilion, hung with small jingling bells and surmounted by a crescent and a star. The Turkish crescent, or "jingling Johnny," as it was familiarly called in the British army bands, was introduced by the Janissaries into western Europe, but it has fallen into disuse now, having been replaced by the *glockenspiel* or steel harmonica.

CHINESE SCULPTURE. The historical records about sculptural works in China do not begin until the Ch'in dynasty (249–206 B.C.); the earliest refer to the 12 colossal statues of "the giant barbarians" and the bell-frames in the shape of monsters "with stags' heads and dragons' bodies," which the great emperor Ch'in Shih Huang Ti ordered to be cast from the weapons of war collected throughout the kingdom. These enormous bronze statues which were placed before one of the imperial palaces near Hsien Yang, on the Wei river in Shensi, are mentioned by Lu Chia, an author who lived from the Ch'in to the Han dynasty, and by several later chroniclers such as Chang Heng (d. A.D. 139) who speaks of "the metal barbarians sitting in a row." At the end of the later Han dynasty Tung Chow melted "ten bronze men into small cash, also the bell-frames"; the two remaining ones he set up inside the Ch'ing Ming gate at Ch'angan but these were also lost during the 4th century, when a local ruler tried to remove them but found them too heavy for the muddy roads, the result being that one was melted down into cash, the other thrown into the river. Nothing, however, is known about the artistic character of these statues, but their well recorded history proves that they were considered extraordinary both for their motives and their size.

Ch'in Dynasty.—The only sculptures now remaining which possibly might be attributed to the Ch'in dynasty are some decorative animals in bronze. Most of these are of small size and placed on the lids of sacrificial vessels, but nevertheless with a well developed sculptural character. A larger example,—sometimes ascribed to the Ch'in period—is a statuette, that represents a reclining bull (now in the possession of L. Wannieck, Paris). It is said to have been found together with some bronze vessels, decorated in Ch'in style, at Li Yü in northern Shansi, but to judge by its style, it can hardly have been executed before the 6th century A.D. (Northern Wei dynasty). We illustrate it, however, as a particularly fine example of early Chinese animal sculpture.

Among other bronze animals which have been ascribed to the Ch'in period should be mentioned a large dragon or hydra with crested neck and flame-like wings at the shoulders and the loins, in the collection of A. Stoclet, Brussels. It is in marked contrast to the bull, fierce, fantastic, grotesque to the utmost without any connections with nature, and must, indeed, be earlier in date, though hardly of the Ch'in period. Other fantastic animals such as interwinding dragons or felines appear at the handles of some large bells in Ch'in style.

New efforts were evidently made in different directions during this short period which, in the field of art, was simply an introduction to the classic age of the Hans. The rigid ceremonial art of earlier times is gradually modified by a more direct and vivid interest in nature. The Chou art (1122–249 B.C.) was preeminently symbolic and geometrical. The art of the Ch'in and the Han periods aimed at the presentation of the actual rhythm of things, the inherent life and significance of the artistic forms.

The Han Dynasty.—Most of the Han monuments have evidently been destroyed; yet, to judge from those which remain as well as from minor plastic creations in bronze and clay, Chinese sculpture was at this early period much better fitted to treat animal motives than human shapes. It is only in the reliefs that the human figures reach an importance comparable to that of the animals, and these are, on the whole, more like paintings translated into stone than real sculptures. With the exception of the small tomb statuettes made as substitutes for real people, human representations are quite rare and artistically much inferior to the representations of animals. The Chinese have never considered the human figure an artistic motive in itself, but simply used it for expressing an action or a state of consciousness. They have taken greater interest in types, postures and motives of drapery than in the bodily form or the muscular organism. The case is quite different with the animal sculptures. They may adhere to certain types or formulae characteristic of the period to which they belong but their artistic importance depends mainly on the rendering of their organic form and vitality. The best among them are monumental creations, hardly inferior to animal sculptures of any other period or nation. The conventionalization, which is more or less preponderant during the early epochs, does not convey an element of immaterial abstraction but serves to accentuate the muscular organism, the energy of movement, the monumentality of the form, all that makes the animals great and convincing as works of art.

Bronze, Clay and Stone Work of the Han.—Among the great number of wild and domestic animals represented in bronze, clay and stone during the Han period we may choose as examples some bears executed in bronze. The majority of these bears are quite small, intended to serve as feet for sacrificial vessels, but there are also some of a larger size which have the character of free standing sculptures. The two best are in the Gardner museum in Boston. These are represented in a squatting posture, stretching their heads forward with a friendly roar. The modelling of the limbs is not carried very far, yet it is sufficient to awake an impression of suppleness and force. The artist has not been afraid of exaggerations in the characterization of the lumpy forms or the telling postures. The heavy weight of the body supported by the broadly placed forepaws, the elastic power of the enormous legs, the softness of the bulky paws and the long nose which seems to form a direct continuation of the ears, are rendered with a power of conviction and a sense of monumental unity that are rarely found in later animal sculptures.

It should also be noticed that in their representations of animals the Chinese have quite often combined two or more into a group. They have composed them in the most intricate positions and

built up groups which satisfy the highest requirements of plastic art. Most of these groups are on a relatively small scale, but they are nevertheless truly monumental. The finest results are achieved in groups of fighting animals, because the bodies are here represented in their highest tension, in the full development of their muscular effort, and so closely interlaced that they complete each other perfectly in the expression of the plastic idea. The same is also true of some of the animals which are composed into an architectural unity with monuments such as the tomb pillars in Szechuan (which will be mentioned below).

Tomb Statuettes of the Han.—The greatest variety of animal types may however be found among the clay statuettes made for the tombs. The material was most easily handled and thus invited all sorts of individual variations, and as these clay sculptures were executed as substitutes for living animals, which in earlier times followed their dead masters into their tombs, it was natural that they should be made as lifelike as possible. The majority are domestic animals such as horses, sheep, dogs, pigs, hens and ducks in various sizes, the smallest hardly more than two or three inches high, the largest measuring a foot or more. They were usually executed in clay moulds but sometimes modelled by hand, and the best among them have retained a spontaneous freshness and vivacity which make them very entertaining. Proportions and shapes are treated with a great deal of freedom. The dogs have enormous heads, the horses have necks which curve like high arches, and the pigs have snouts like bowsprits, yet the exaggerations serve simply to accentuate the typical features of the various animals.

Besides the animals there are human *ming ch'i,* or tomb statuettes, made as substitutes for living people, such as servants, and wives who formerly were buried alive with the husbands. Most common amongst these statuettes from the Han period are the slender ladies in long robes with wide sleeves reminding one of the Japanese kimonos. They stand usually in very quiet postures simply with a slight inclination of the large round head, but occasionally we find them represented in a dancing movement, though with closed feet, swinging their bodies and their arms in a rhythmic fashion.

Stone Sculptures of the Han.—Stone sculptures on a large scale were, no doubt, also executed in steadily increasing numbers during the Han period, though comparatively few of them have been preserved. Among the earliest which can be approximately dated are the animals at the tomb of General Ho Ch'ü Ping, situated at the Wei river some 20 m. N.W. of Sianfu. They were discoverd by Ségalen and Lartigue during their explorations in 1914 and more completely dug out by the latter in 1923. Lartigue has also published them in an article in the German magazine *Artibus Asiae* (1927) in which he presents some evidence for the supposition that these statues were executed about 117 B.C., the year of the death of the famous general. He thinks that the statues, which represent a horse standing over a fallen warrior, a reclining horse and a buffalo, were placed in front of the mound, and that their present quite irregular positions have been caused by the shifting of the mud. Besides these, complete sculptures may, however, be seen in the neighbourhood of the mound, a large block with a mythological figure, executed in relief, and fragments of some animal sculptures which seem to indicate that this large composition never was completely finished. It is difficult to appreciate the artistic importance of these large statues without seeing the originals, but if we may draw some conclusions from the reproductions, the sculptures are comparatively undeveloped from an artistic point of view. This is particularly true of the main statue, the horse standing over a fallen warrior. The composition is indeed significant but the formal treatment does not seem to do justice to the motive. The short-legged horse with an enormous head is more bulky than monumental, and the figure under its belly is simply a large block. Here is little of that intrinsic energy which is so prominent in some of the minor sculptures already mentioned This impression is, however, to some extent counteracted by the reclining horse and the buffalo which, even if they are heavy and bulky with stumpy legs, reveal a very sensitive artistic treatment, particularly in their expressive heads. Here one may discover a touch of that excellent animal psychology which is one of the greatest assets of Han art, a characterization which, to some extent, makes up for the shortcomings in other directions.

Sculpture Developed For the Dead.—Other stone sculptures from the beginning of the Han dynasty which might serve for comparison have not come to light, though it is more than probable that they have existed, because this tomb was hardly an isolated case, and broadly speaking sculpture in stone as well as in clay had its origin in the decoration and the arrangement of the tombs. It was for the dead rather than for the living that the Chinese developed their creative activity in the field of the plastic arts. As proof of this may be quoted not only the various classes of clay and stone sculptures mentioned above, but also numerous reliefs executed for the decoration of the "spirit chambers" of the tombs and the sculptural pillars placed in front of the mounds. These monuments marked as a rule the beginning of the "shen tao" (spirit path) which led up to the tomb and which in later times was farther and farther extended in a straight line from the mound towards the south. The interior of the tomb consisted often of two or more chambers (as also may be observed in contemporary Korean tombs), the first being a kind of ante-room called the "spirit chamber," where the soul of the deceased was supposed to dwell, while the coffin was placed, together with various vessels and other paraphernalia of bronze or clay, in the back room. The main decoration, be it in sculpture or painting was concentrated in the ante-room where the walls often were covered with representations from ancient history and mythology or with illustrations with a moral import.

THE METRO-
SCULPTURE OF THE SUI PERIOD

Tomb Pillars.—Quite a number of the decorative pillars which formed the gateway to the "spirit road" are known from central and western China, particularly the provinces of Honan, Shantung and Szechuan. They are usually constructed on a rectangular plan of large and well-fitted stone blocks reaching a total height of 15 to 18 feet. When completely preserved they consist of a moulded pedestal, a very broad shaft and a cornice over which the roof projects quite far. But the form varies somewhat in the different provinces; thus the pillars in Honan, of which the best known stand at Têng Fung Hsien on Sung Shan, are very broad and provided with projecting buttresses. Otherwise they are quite simple without any particular development of the cornices and decorated with ornaments and figures in very low relief. The earliest of these Honan pillars is dated A.D. 118, the latest A.D. 175

The pillars in Szechuan have usually no buttresses, but they are higher and characterized by a richer architectural composition; their upper parts, the cornices and friezes under the projecting roof are particularly well developed. We find here, reproduced in stone, the beam ends and brackets so characteristic of Chinese wooden architecture, and between these are sculptural decorations executed in high relief, sometimes almost in the round. These pillars are all from the later Han dynasty, but only one of them, the pillar of Fung Huan at Ch'iu Hsien, is dated by an inscription which contains the year A.D. 121.

Symbolic Decorations of the Han.—More important for their sculptural decorations are, however, two pillars in the same neighbourhood erected at the tomb of a man called Shen On their shafts are representations of the symbols of the four directions; *i.e.,* the red bird of the South, the white tiger of the East, the blue dragon of the West and the black tortoise of the North, animal representations which, with regard to energetic rhythm of line and grand decorative stylization, may be compared to the best works in bronze or clay known from this classic epoch. At the corners of the entablature are seated human figures which seem to carry the projecting beams on their shoulders, and, on the

middle of the south side, a kind of *t'ao t'ie* (glutton) appears between the beams. All these figures are executed practically in the round and most skilfully composed into the architectural scheme of the monument. The very high frieze is divided into two sections, of which the lower one is decorated with hunting scenes in quite low relief and the upper one with some larger figures in high relief. One may observe here men riding on stags, horse-like animals running along with the swiftness of the wind, and hunters who aim with their bows above their heads or grasp the pursuing leopard by its tail. Here is the same free-play with animal and human forms as may be observed on some of the inlaid bronze vessels or on the glazed Han urns with relief friezes. The motives seem to have some reference to the life beyond the tomb, though they represent this with a naturalness and an intensity of movement which make them appear like scenes from real life. The style reveals something of the same energy and nervous tension that characterizes the small bronze ornaments of this period, and it can hardly be explained without accepting an influence from west Asiatic sources, though the Chinese transformation of the west Asiatic tradition is more complete in the large stone sculptures than in most of the minor bronze ornaments.

Dramatic Expression of the Pillars.—The majority of the stone pillars in Szechuan, of which at least a score were discovered by Ségalen and Lartigue during their exploration in 1914, show the above mentioned combination of friezes with flat reliefs and tri-dimensional representations of animals and human figures on the entablature. The motives vary, some being historical or legendary, others religious or mythological, but they are all more or less imbued with a dramatic expression, and executed in a form of high decorative beauty.

Much simpler than these are the pillars which stood at the entrance to the tomb of the Wu family at Ch'ia Hsiang in Shantung. They were erected about the year A.D. 147 and they are still in their original place, although the tomb-area has become a large pit, usually filled with water. The pillars are provided with buttresses and a small superior storey on the projecting roof but their sculptural decoration consists simply of quite low reliefs representing dragons, tigers and birds, in decorative transformation besides legendary illustrations with a moral import, framed by geometrical ornaments of the same kind as may be found for instance on the mirrors of the Han period.

Reliefs of the Han.—The same kind of motive, executed in a strictly conventionalized linear style, appears also on the large stone slabs which used to be arranged along the walls of the tomb chamber in the tomb, but which are now transferred to a primitive little store-room where they stand without any kind of order. These reliefs from the Wu Liang Tzu tomb have become known all over the world through numerous series of rubbings taken of them since the 18th century, and reproduced in many Chinese and European publications. Two or three of the reliefs have found their way into Western collections, though it should be noticed that the majority of the stone reliefs, said to come from Wu Liang Tzu, are simply modern imitations, made on the basis of rubbings.

Legendary Motives.—Nothing is more entertaining than to follow with the aid of Chavannes interpretations, the legendary motives represented in these reliefs and thus to learn something about classical Chinese examples of filial piety, matrimonial fidelity, the faithfulness of loyal citizens, the valour of great heroes, not to mention the quasi-historical traditions about the great Yü and Ch'in Shih Huang Ti or the mythological stories about the king of the East, Tung Wang Kung, and the queen of the West, Hsi Wang Mu. Very common motives in these reliefs are the long processions of riders and carriages and the rows of men on horseback escorting a carriage, which may be representations of the journey of the deceased to Hades.

The compositions are arranged in horizontal storeys, with single rows of figures, animals, trees, houses and the like, appearing as silhouettes against a neutral background. The artistic expression lies mainly in the contours, and in the engraved lines; the modelling of the forms is very slight. These reliefs may thus hardly be called sculpture in the real sense of the word, but rather paintings or drawings translated into stone. We have reason to suppose that they were made after such patterns and reproduce popular wall paintings which existed in some contemporary palaces, a supposition which is supported by the poet Wang Yen Shou, who describes the wall paintings in the Ling Kuang palace executed about the middle of the 2nd century A.D. He mentions in his description mythological illustrations of the same kind as may be seen in the Wu Liang Tzu reliefs besides "many riotous damsels and turbulent lords, loyal knights, dutiful sons, mighty scholars, faithful wives, victors and vanquished, wise men and fools," motives which correspond more or less to those appearing on the stone reliefs from Wu Liang Tzu and other places in Shantung.

Bactrian Types.—It has been claimed that the proud horses of these reliefs were of Bactrian origin. This is possible but the Chinese sculptors were certainly less guided by observation of nature than by artistic models, be it in bronze, clay or textile. They have accepted and further developed a definite type of horse which probably existed in the art of the Hellenized west-Asiatic countries.

Less Hellenistic and more definitely Scytho-Iranian in character are the winding dragons and heraldically placed tigers which appear in one or two of these reliefs. They belong to the same great family of ornamental animals which we also met on the stone pillars in Szechuan, and may thus be said to form some additional proofs of the general acceptance of this kind of animal sculpture during the Han period.

Still more remarkable examples of the same stylistic current are the two lions which stood at the entrance to the tomb of the Wu family (at the sides of the above-mentioned pillars) but which are now more or less buried in the mud. The anatomical character of the only visible one is rather free. It is, indeed, no common lion but a descendant of those proud animals which stood at the royal palaces in Susa and Persepolis and whose artistic pedigree may be traced to Chaldean and Assyrian art. The form is supple, the body is thin, the whole animal is dominated by the broad curving neck which comes so far to the front that the head almost disappears and the neck continues in the enormous jaws. At the shoulders one may observe traces of small wings, though they have been practically worn off by time. Such a creation has hardly been shaped from nature. Even if single lions now and then were sent as tributes from western Asiatic nations to the Chinese emperor, these were hardly known by the people in the provinces, and as there were no other lions in China, we may well suppose that the inspiration for such animal representation was drawn from examples of Iranian art rather than from living models.

Animal Statues.—To the same group of animal statues from the end of the Han-epoch may also be assigned two winged tigers at the tomb of K'ao Yi at Ya Chou Fu in Szechuan, which have been published by Ségalen and Lartigue, and the enormous seated lion—which has served as a plinth for a pillar in the Okura museum in Tokyo. There are furthermore some minor animal statuettes of the same type but they hardly need detain us as they only verify what has already been said about the artistic style and derivation of these sculptures. Nor do we need to stop at the human figures executed in stone on a large scale, because their artistic importance is much inferior to that of the animals.

Animal Sculptures of the Six Dynasties Period.—During the centuries which followed the fall of the Eastern Han dynasty (A.D. 214) artistic activity in China lost some of its intensity. The times were restless, filled with war and political upheaval. The empire was again divided into several minor States, to begin with, the Three Kingdoms, Wu, Shu and Wei, and later on, after 223, into a northern and a southern half, the former being under the domination of the Tartars, among whom the Toba tribe came out the strongest and took the name of the Northern Wei dynasty, while the latter was ruled over by a number of short-lived native dynasties—Sung, Ch'i, Liang and Ch'en—which had their headquarters at Nanking. We know very little about the artistic activity during these times but it seems that the

stylistic traditions of the Han period remained in force also during the 3rd and 4th centuries of our era. Some tomb reliefs, mainly from Shantung, executed in a kind of coarser Han style, may well be of this transition period, and the same may be said of a number of minor plastic works in bronze and clay.

The general evolution can be followed most closely through the small tomb statuettes; they reflect the variations in taste and fashion better than the large stone sculptures. Among them are real *genre* figures represented in various occupations such as music-making, feeding the hens, or with children in their arms, and we may observe how the fashion is changed from the simple "kimono" to an elegantly draped mantle over a tightly-fitting undergarment and how the head-dress becomes higher and more decorative. These tomb statuettes and minor animals in terra-cotta originate mainly from Honan, whereas the larger stone sculptures of this same period are executed for the reigning dynasties in Nanking. These monuments which form one of the most important groups within the domain of Chinese sculpture, have been more or less identified and reproduced by various explorers.

The largest among these lions and chimaeras measure up to 10 or 12 ft. in length and may still be seen at their original places, but some smaller ones, 4 to 6 ft. long, have found their way to Western collections. They all represent winged, lion-like animals but it is possible to distinguish two main types, *i.e.*, the chimaeras, which are a kind of cross between dragons and lions, and the real lions which have wings on their shoulders but no feathers or scales on their bodies and no ornamental beard. The former seem to have been considered the nobler, because they were employed as guardians at the tombs of emperors, whereas the lions stood at the tombs of princes and dukes.

Early Chimaeras.—The earliest chimaera which can be dated stands at the tomb of Emperor Sung Wen Ti (d. 453). It is a colossal and, in spite of its dilapidation, still imposing animal, largely covered up by a heap of refuse, so that the statue had to be dug out whenever it was photographed. The upper part of the head is lost and the surface of the grey limestone is very much worn but it is still possible to see that the body as well as the legs have been covered by ornamental scales or feathers and that the animal had wings not only at the shoulders but also at the ears.

The second earliest in date of the chimaeras which still remain at their original sites is the one at the tomb of Emperor Ch'i Wu Ti (d. 493). The dimensions are somewhat smaller but the animal is more completely preserved. The long body has a more dragon-like character, the legs are comparatively short and the tail well developed. The most imposing part is, however, the enormous head with the open jaws from which the ornamental beard hangs like a long tongue. One may here observe three pairs of wings as well as feathers drawn in spirals over the whole body.

Sixth-century Chimaeras.—The same proud bearing characterizes the chimaera at the tomb of Emperor Liang Wu Ti (d. 549). The movement of the long and supple body is still better developed and it receives a most effective continuation in the enormous curve of the neck. The animal is moving forward in an ambling fashion; we feel its vigour and suppleness. The wings and the feathers are indicated in quite low relief or simply engraved.

This nobility and energy are carried still further in the two large chimaeras which now stand in the University Museum at Philadelphia. We have no information whence they come, but they illustrate a further evolution of the style of the chimaeras at the tomb of Emperor Liang Wu Ti, which would date them shortly after the middle of the 6th century. It is possible that they stood at the tomb of some of the emperors of the short Ch'en dynasty which followed after the Liang, such as Ch'en Wu Ti (d. 559) or Ch'en Wen Ti (d. 566). In comparison with these beasts, the earlier chimaeras appear almost like domestic animals. The fantastic wildness and the seething energy are here given free outlet. The legs are stretched, the bodies drawn, the head is wildly thrown backwards, the chest pushed forward into a large curve, and all these movements are accentuated by engraved lines which give the impression of taut steel springs. Besides these large ones several minor chimaeras are known but none of them reaches the extraordinary expressiveness of the last-mentioned.

Winged Lions.—The largest of the winged lions still remain *in situ*, not far from Nanking; their weight and colossal dimensions have made their removal impossible, but some of them are so far decayed that, if nothing is done to protect them, they will soon disappear. The earliest and most important stand at tombs of various members of the Liang family, *i.e.*, the brothers of the Emperor Wu Ti, Prince Hsiao Hsiu (d. 518), Prince Hsiao Tan (d. 522) and the cousin of the emperor, Duke Hsiao Ching (d. 523). Besides these, two or three pairs of large lions are in the same neighbourhood, at Yao Hua Men, to the east of Nanking, but they are later and artistically inferior. The anatomical difference between the lions and the chimaeras is, as already said, not very important. The former as well as the latter are feline animals with an enormous curving neck and wings but they are not provided with scales or feathers, nor do they have any ornamental beard like the chimaeras, only a large tongue which hangs down from the open jaws over the projecting chest. They are all represented in an ambling posture, majestically walking or coming to a sudden standstill, when the fore-legs are strained and the hind-legs bent. The head is lifted high on the proudly curving neck, the forms are full, the limbs heavier than in the chimaeras. Their massiveness is at least as imposing as the concentration of power in their enormous limbs. Most eaten by frost and water are the lions at the tomb of Duke Hsiao Ching which is now covered by a watery rice field in which the lions sink up to their shoulders.

SCULPTURE OF THE NORTHERN WEI PERIOD

Lions of Hsiao Hsiu Tombs.—Better preserved and more completely visible are the two colossal lions at the tomb area of Hsiao Hsiu, now covered by the village Kan Yu Hsiang, and here remains one row of the other monuments which flanked the "spirit road," *i.e.*, two large tablets with inscriptions carried by tortoises and a fluted column on a plinth composed of winding dragons. This seems to be the earliest preserved "tomb alley" in China, an arrangement known from a great number of later tombs. The lions are of the same family as those already described, the fact that they have wings is in itself a proof of their dependence on Persian art. It should, however, be remembered that the Achaemenian and Sassanian animals were descendants of the Assyrian which must be regarded as the fore-fathers of all the greatest Asiatic and a good many European lion sculptures. To what extent the Chinese really knew such models is a question which cannot be discussed here; it is in any case evident that they transformed the foreign models quite freely, not to say fantastically, in harmony with their native traditions. These animal sculptures form stylistically a direct continuation of the plastic art of the Han period. Yet, they indicate that a new wave of Western influence reached China at this time on a more southern route than through the north-western nomads. These lion sculptures do not appear in the northern provinces which were dominated by the Tartars. They belong to the more southern provinces where the old Chinese civilization and the creative spirit of the "Han people" never were completely subdued by foreign elements.

Religious Sculpture of the Six Dynasties.—When Buddhist sculpture was introduced into China it had passed through a long evolution in India and Central Asia; the principal iconographic motives, symbols and attributes were all developed into definite forms; the Chinese took them over just as they took over Buddhist scriptures; and whatever modifications they may have

introduced concerned more the artistic interpretation than the motives themselves. It should never be forgotten that they were greater artists than any other people of the Far East, and when Buddhist art took root in China, the country was by no means devoid of sculptural monuments. There were (as we have previously seen) artistic traditions which could not be forgotten, only modified when applied to Buddhist motives. The Buddhas and Bodhisattvas were, of course, represented in human shapes but the artists could not enhance their significance by accentuating their physical organisms or their likeness to ordinary human beings nor could they change their general shapes or postures if they wanted to be understood. The iconographic rules are indeed much more exacting in Buddhist than in Christian art, and the motives are more limited in their artistic scope.

Religious Symbolism.—The great majority of the Buddhist sculptures represent isolated figures, seated or standing in very quiet postures without any attempt at movement, except certain symbolic gestures. The heads are made according to quite definite types, somewhat changing with the periods and localities, but it is rare to meet heads with individual expression or portraitlike features. The bodies are as a rule entirely covered by long mantles or rich garments according to the rôle or meaning of the figure; they have hardly any importance of their own but serve simply as a substratum for the rich flow of the mantle folds which, particularly in the early sculptures, conceal the forms much more than they accentuate them. Even in figures which are represented almost nude, such as the guardians at the gate (*Dvarapalas*), the representation is not really naturalistic; their Herculean forms and muscular movements are altogether exaggerated and their significance is symbolic.

The earliest dated Buddhist sculptures in China, known to us, are small bronze statuettes of a greater historical than artistic importance. Some of them are provided with inscriptions which make it possible to fix their date, the earliest being of the years 437 and 444, whereas the earliest dated Buddha in stone is of the year 457. These small statuettes represent standing or seated Buddhas or Bodhisattvas against a leaf-shaped nimbus decorated with engraved flame-ornaments. The figures are mostly of a very moderate artistic importance recalling by their types and draperies the Graeco-Buddhist art of north India. The large nimbuses behind these small figures constitute, however, a feature which is not known in Gandahara sculpture.

Yün Kang Cave Temples.—The greatest *ensemble* of early Buddhist sculptures in China is to be found at the Yün Kang cave temples near Ta Tung Fu in Shansi where the Northern Wei dynasty had its capital until 494, when it was removed to Loyang in Honan. The work at these cave sculptures started about the middle of the 5th century and was continued towards the latter part of the 6th century. Amongst the rich material displayed at this place one may observe different stylistic currents some originating from Central Asia and India, others more closely connected with earlier forms of Chinese art. Here are ornaments of a distinctly Iranian character, and architectural forms of the same type as on reliefs from Taxila and Peshawar, but also some decorative motives recalling the art of the Han period. Among the figures there are some curious examples which form a link with Central Asiatic art, *e.g.*, the five-headed and six-armed god who sits on a large bird with a pearl in its beak. This is no doubt the Garuda-raja, the bird of Vishnu, which also may be seen in some paintings from Tun Huang. This and other Hindu divinities of a similar kind, which appear in the Buddhist pantheon at Yün Kang, testify that artistic influence from central and western Asia reached China in connection with the introduction of Buddhism.

Artistic Expression.—Most famous among the figures here are the colossal Buddhas and Bodhisattvas which, however, seem to us artistically least interesting. A certain conventional type and fold design have in these figures been enormously enlarged without any intensification of the rhythmic motives or the artistic expression. More artistic expression and beauty may be found in some other figures at Yün Kang which are less closely allied to Indian models and more imbued with the traditional Chinese feeling for rhythmic lines and elegant form. The figures themselves are quite thin and flat, sometimes hardly modelled into full cubic volume, and they are entirely covered up by very long and heavy garments. The folds of these are pressed and pleated on the very thin shapes and uniformly arranged on both sides of the figures in long concave curves, forming a kind of zigzag pattern at the border; the contours are very tense, with the elasticity of drawn bow-strings. When this type of draping is fully developed the drawn out, curving mantle-folds may suggest wings.

Temple Grottoes at Lung Men.—The same energetic style as in the best Yün Kang sculptures may also be observed in some of the statues in the famous temple grottoes at Lung Men in Honan which were begun shortly after the Northern Wei dynasty had transferred its capital to Loyang (494). During the last decade these caves have been so badly destroyed that hardly 10% of the original sculpture still remains; all the rest is either smashed or beheaded, some of the heads being replaced by clay substitutes of a very provincial type. The most beautiful and earliest sculptures at Lung Men are to be found in the so-called Lao Chun Tung cave which is decorated from ceiling to floor with a great number of niches of varying sizes in which Buddhas and Bodhisattvas are grouped, either alone or together with adoring bikshus or other attendants. The majority of these sculptures were executed in the 3rd or 4th decade of the 6th century, but only some of the minor reliefs remain still in a fair condition. Yet some characteristic positions may be observed, for instance the cross-ankled Bodhisattvas which represent Maitreya, the coming Buddha, while the Buddha Sakyamuni is seated with legs straight down. The stylization of the folds is carried out according to the same patterns as in the Yün Kang caves, but the stone is harder and the technique is superior to that of the earlier Yün Kang sculptures. Some of these Lung Men sculptures have certainly been among the finest works of their kind in China.

Another variation of the Northern Wei period style may be observed in the sculptures which decorate the temple caves at Shih Ku Ssu, near Kung Hsien in Honan. The work was here started about the same time as at Lung Men but the material is of a softer kind and the technique is not quite so fine. The large central Buddha at this place, which now stands up to its knees in mud, is a broad and block-like figure modelled in very large planes, with a remarkable cubistic tendency, which also may be observed in several minor heads from the same place, now dispersed in various European and American museums.

Buddhist Stelae.—Besides these cave sculptures of the Northern Wei period should be mentioned a large number of Buddhist stelae, *i.e.*, slabs with figures in high relief, varying in size, some up to 12 ft. high, others quite small. Their decoration consists generally of a combination of niches with Buddhist figures and ornamental borders. On the back of these slabs are often found long rows of figures in flat relief representing the donors of the monuments. This form of stelae was probably developed from the earlier type of inscribed memorial stones, as used in China since the Han dynasty. It is worth noticing that we find at the top of the Buddhist stelae the same kind of winding and interlacing dragons as on the slabs which were raised at the tombs; their fierceness and energy of movement seem to reveal their derivation from the Sibero-Asiatic art, based on Scythian traditions which, indeed, had a great influence on the development of the ornamental style of this period.

Transition Period.—The stylistic ideals of the Northern Wei period retained their importance until the middle of the 6th century. About this time a new wave of artistic influence reached China from northern India. It may be quite clearly observed in some of the monuments which were executed during the Northern Ch'i and Northern Chou dynasties (550–581). The best cave sculptures from this time existed, at least a few years ago, at T'ien Lung Shan not far from Taiyuan-fu in Shansi. They were started in the Northern Ch'i period and continued, with some intermissions during the Sui and T'ang dynasties.

Sculptures at T'ien Lung Shan.—The earliest sculptures at T'ien Lung Shan are to be found in the caves no. 2, 3, 10 and

16, probably executed between 560 and 580. The system of decoration in the first two caves consists of three large groups, one on each wall representing a seated Buddha accompanied by two Bodhisattvas and, in some instances, also by adoring monks and donors, characterized with striking realism. The main figures are executed in very high relief, giving almost the impression of free-standing forms, yet there is a certain flatness about them, noticeable particularly in the Bodhisattvas which stand turned half-way towards the central Buddha and whose garments —arranged in pleated folds—spread out in wing-like fashion at the sides. They are not very far removed stylistically from corresponding figures on later Wei monuments, though their heads are less archaic both in shape and expression.

The maturest examples of this transition period—possibly executed as late as 580—are to be found in the 16th cave at T'ien Lung Shan, where all the three walls are decorated with large groups of Buddhas with Bodhisattvas and other attendants placed on raised platforms, the fronts of which were decorated with representations of dwarf musicians. The central Buddhas are lifted into commanding positions on high pedestals in the form of lotus-flowers or altars; their shapes are full and well rounded, their heads comparatively small for the strong bodies. They are all seated in the same cross-legged posture, with bare feet and hands in the *abhaya* and *vara mudra* (gestures signifying "without fear" and "charity"). Their mantles, which are made of a very thin material, are draped only over the left shoulder, leaving the right bare, and the folds have practically no relief. Buddhas clothed in this fashion are very rare in Chinese art; they may occasionally be found in later T'ang sculpture but at this early period they are certainly surprises.

Foreign Influence.—The most probable explanation of this apparent anachronism in the style of the Buddhas seems to be that they were made from foreign models or by foreign artists while the less important side figures were carved in accordance with the indigenous principles of style. The figures are altogether Indian in spirit and form. It is hard to believe that Chinese artists would have been able to reproduce Mathura models so faithfully as we find them here, and it may at least be claimed that they have never done it better, either before or after. Possibly some Indian artist, well acquainted with the Mathura school, worked for some time at T'ien Lung Shan.

The same general types and principles of style which characterize the sculpture at T'ien Lung Shan may also be found in some isolated statues coming from this or a similar centre of sculptural activity. The most characteristic feature of all these figures is the cylindrical shape indicated in the legs and arms, as well as in the shape of the whole body, which often stands like a column on the lotus pedestal. Nothing can be more unlike the comparatively flat and angular shapes of the Northern Wei figures, which even when they have a more developed plastic form are linear rather than rounded.

Sculptures from Chihli Province.—Another provincial variation of the transition style may be seen in the sculptures from Chihli, the present metropolitan province, and particularly from Ting Chou where the supply of a beautiful white marble was abundant. The artistic quality of these sculptures is however quite uneven; the best of them stand on the highest level of Buddhist art in China, while the poorest are hardly more than ordinary artisans' work. Several figures of this group might be quoted as proofs of what already has been said about the plastic formula during this transition period. Their shapes are more or less cylindrical, their heads mostly large and heavy. One may notice a general tendency to make the figures narrower towards the feet and to broaden them towards the shoulders. The thin garments fit tightly over the bodies and their softly curving folds are indicated in quite low relief or simply with incised lines. Good examples of such statues are in the Metropolitan Museum in New York. If we place such a figure beside some characteristic example of the Northern Wei art, we may observe two opposite tendencies of style. In the earlier works the mantle folds and the contours are stretched and bent outward at the feet, the shoulders are narrow, the heads small; the rhythm is rising. In the later ones the rhythm is falling instead of rising, the tempo is slow, not without heaviness; there is no bending of the contours, they are falling almost straight down; the mantle hangs over the body and it is only towards the feet, where the circumference becomes smaller, that a certain acceleration of the tempo is noticeable.

The Sui Dynasty.—The sculptures of the Sui period (589–618) form, stylistically, a direct continuation of those of the transi-

BY COURTESY OF THE METROPOLITAN MUSEUM OF ART

SCULPTURE OF THE TRANSITION PERIOD OF THE NORTHERN CH'I DYNASTY

tion period during the Northern Ch'i and Chou dynasties. Most of them are still examples of the transition style, but a few may well be classified among the most perfect works of religious statuary in China. Conditions were particularly favourable for the flourishing of religious art, and the formal development had not yet passed the point where it becomes an end in itself. Sui sculpture is, on the whole, quite restrained in its formal modes of expression and its interest in nature is slight, but it marks nevertheless a distinct progress in the representation of actual forms

T'ien Lung Statues.—Some good examples of the particular style of this period are to be found in the 8th grotto at T'ien Lung Shan which is in part preserved, although the soft material has been worn by time and water and some of the statues have been smashed and decapitated. Coming to these statues from a study of the sculptures in cave 16 at the same place (mentioned above), the first thing that strikes one is that they are not at all Indian in their general appearance. The Buddhas are seated in the same postures as the earlier ones but vested in the Chinese fashion with an upper garment covering both shoulders and with a less hieratic bearing of the stiff bodies. The shoulders are not so broad, the waist less curving, the forms are quite undifferentiated, but the heads have increased in size and have a more human air. They are certainly more Chinese, though in a provincial sense, and they are executed by inferior artists with little feeling for rhythmic lines and decorative beauty.

Most interesting are the two pairs of Dvarapalas (guardians) outside this cave. One pair is placed at the sides of the entrance, the other at each side of a tablet near by which still contains traces of an inscription of the Sui dynasty (said to be dated from about 589). The attitudes of these guardian figures are dramatic, not to say strained. The movement of the arms is jerky, the turning of the heads, which are looking over the shoulder, is violent. The impetuosity is, indeed, much greater in these figures than in the Dvarapala statues at the earlier caves, but whether they have gained in sculptural quality as much as in dramatic force is less certain.

Typical expressions of the plastic formula of the Sui period are also to be found among the sculptures from Chihli, easily recognizable by their material which is a micaceous white marble. Common to them all is the general shape which is no longer simply pillar-like or cylindrical, but ovoid. The contours are swelling out over the hips and elbows and gradually draw closer toward the feet and over the head. Thus a general formula is created, and it

is often repeated on a smaller scale in the heads. The same rhythm is taken up by the folds which in some of the figures form a succession of curves over the front endowing them with a more complete harmony and repose than may be expressed by any other shape or formula known to us.

Shantung Sculptures.—The richest and most varied provincial group of sculptures from the Sui period is to be found in Shantung. The religious fervour and interest in establishing Buddhist temples and sanctuaries seem to have been particularly great in this part of the country and, to judge from the sculptures still preserved in several of these caves, there must have existed an important tradition of religious art which was now revived by various masters of no common ability. The earliest caves are at T'o Shan and Yü Han Shan; at the latter place many of the figures are dated in the 4th, 5th and 6th year of the K'ai Huang era (584–586), but unfortunately they are largely restored with plaster and crude colouring.

The great sculptures in the second and third cave at T'o Shan belong practically to the same stylistic group as those at Yü Han Shan. None of them bears a definite date, but, to judge from their style, they must have been executed about the same time as those mentioned above, *i.e.*, about the middle of the '80s. The typical Sui formula for single figures has been enlarged on an enormous scale, not without some loss of plastic beauty and intimacy. The great Buddhas which are seated in cross-legged position on a low pedestal impress us more as a kind of architectural monolith than as plastically conceived sculptures. It is only the folds of the hem, falling over the pedestal, that have a livelier rhythm; here one may observe the very characteristic meandering wave-line which returns in most sculptures of the Sui period, and some overlapping larger curves divided by the no less significant ear-like curves.

Passing from the cave sculptures at T'o Shan to those at Yün Men Shan, which is situated across the valley, means moving into a quite different artistic centre. There are only a few large statues at Yun Men Shan and some of these are in a deplorable state of preservation, but whatever remains here is of remarkably fine artistic quality. No doubt, these sculptures are a little later than those in the caves at T'o Shan, though hardly more than ten years; the dates that are found in some of the small niches at the side of the main figures range from 596 to 599. The figures are not placed in real caves but in flat niches, and may thus be seen to more advantage than most cave sculptures in their original position; the actual play of light and shade adds something to the plastic effect.

The Yün Men Shan Buddha.—The principal group consists of a seated Buddha accompanied by a standing Bodhisattva and another figure which may have been a Dvarapala (now practically destroyed). Close to this is another still flatter niche which never contained any central statue, only a large tablet, which is now removed, and on each side of it two monumental Bodhisattvas.

The great Buddha is seated on a dais in the traditional posture with the legs crossed in front, and entirely covered by the wide mantle. The bearing of the body is, however, quite different; instead of the old stiffness there is a certain ease in the posture, a repose without any strain. He seems to lean against the wall of the niche, moving the head slightly forward as if intent on looking at something in front. The upper garment which is fastened with a string knot on the left shoulder is draped in quite broad curves between the knees. The folds are not simply ornamental or expressive of a linear rhythm, but modelled with fine gradations of light and shade, sometimes even undercut. They have become means of primary importance for creating a sculptural effect. The head is treated in a new individual manner with broad effects of light and shade. The eyes are not closed or half closed, as in most of the earlier Buddhas, but wide open, and the eyelids are undercut, which adds greatly to the impression of life. The lips are also separated by a deep shadow, as if they were opening. The whole treatment is quite exceptional and bears witness to an impressionistic style; strictly speaking, it remains an isolated phenomenon in Chinese sculpture.

The T'ang Dynasty.—It would indeed be wrong to imagine that there is an absolute break or a deep-rooted difference between the sculpture of the Sui and that of the T'ang period; quite the opposite. T'ang sculpture is stylistically an immediate successor to the art of the Sui period. When we, for convenience sake, use the dynastic names and dates also in the domain of art, it should be clearly understood that they do not signify here the same kind of opposites or renewals as in the political history of the country. Artistic evolution in China is a slow and gradual process, which only to a minor degree is conditioned by the political events.

It may also be recalled that the T'ang dynasty reigned during a longer time than most of the preceding dynasties (618–907), and the plastic arts remained by no means the same during this whole period. The production of sculpture was very intense during the first 100 years of the period, but became soon afterwards comparatively weak and insignificant. In speaking about T'ang sculpture we mean the art up to about 725, which may be considered the most mature and perfect kind of Buddhist sculpture in China. It reflects something of the same creative and expansive power that we may observe in other manifestations of T'ang culture. Its best products are characterized by a plenitude, not to say magnificence, that can hardly be found in the art of earlier epochs. The forms grow full and strong, the decoration becomes rich and exuberant, gradually approaching what we should call baroque.

An important element in this evolution was due to the growing inter-communication between China and the western Asiatic centres of artistic activity, particularly the Sassanian empire. Many new impulses were derived thence and grafted upon the old stock of Chinese art, modifying it more and more in the direction of Western ideals of style. Generally speaking, it may be said that the current that came from India was of the greatest importance for the Buddhist sculpture, while the influences from Persian art are most plainly discernible in the ornamentation of minor objects in bronze and silver.

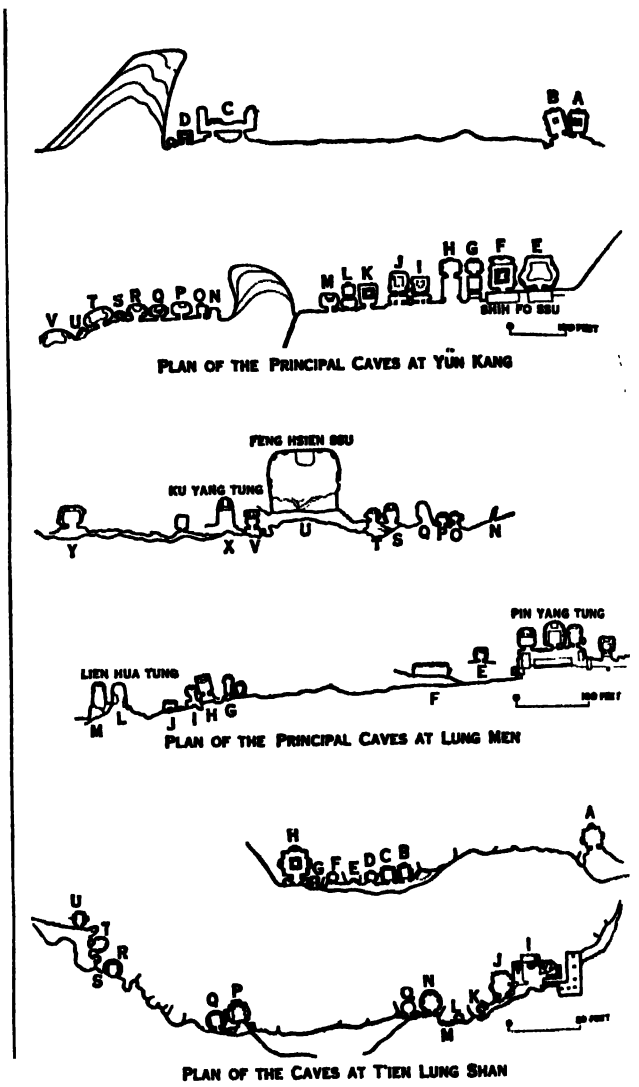
In order to illustrate these two main currents, as well as other important elements of style in the plastic art of the T'ang period, it would be well to take into consideration other artistic products besides stone sculptures, such as objects in bronze, silver, clay and lacquer, which reflect the aesthetic ideals of the time, but this would carry us beyond the limits of this short study. Buddhist statues still form the most important province within the plastic arts of the T'ang period, though it should also be remembered that some large tomb sculptures were executed at this time, including magnificent representations of lions and horses at the tombs of the great emperors, T'ai Tsung (d. 649) and Kao Tsung (d. 683).

The Shensi Sculptures.—The early T'ang sculptures from Shensi, which then was the metropolitan province, are made in a very hard, grey limestone or in a dense yellowish marble. The fine quality of the material demands a highly developed technique in order to yield good plastic effects and ornamental details, and it may well be admitted that as far as workmanship goes many of these statues stand on the highest level of Chinese sculpture, but the artistic quality is often less remarkable. The earliest dated statue of this period known to us is of the year 639; it represents a Buddha seated in cross-legged position on a high, draped pedestal placed in front of a background slab which is bordered like a nimbus with flame ornaments. The figure is draped in a mantle which covers both shoulders, arms and feet, leaving only a small part of the chest bare. The folds are highly conventionalized in the form of thin, rounded creases and arranged in long curves over the body, the legs and the upper part of the pedestal. The decorative effect is altogether more powerful and concentrated than in earlier statues of a similar kind, and the execution is masterly. Although made in stone, the statue gives the impression of a work cast in bronze, an impression which is supported by the dark metallic hue of the hard stone.

Influence of Indian Art.—Some Bodhisattva statues, of which two may be seen in the University museum in Philadelphia, illustrate still better an increasing influence from Indian art not only by their costumes and decorative ornaments but also by their bearing and formal character. They stand no longer in stiff up-

right positions with the weight of the body evenly divided on both feet; the one leg is slightly curved and moved backward, the other serves as a support for the body which consequently is curving, a movement which is continued in the neck and in the more or less marked inclination of the head. The upper part of the body is bare, except for the jewelled necklaces and the narrow scarf draped over the shoulder; the chest is well developed and the waist rather narrow. The *dhoti,* which is tied with a sash round the hips, falls in a series of curving folds over each leg, and these are indicated in the same fashion as the folds of the Buddha mentioned above. It should also be noticed that these figures do not wear a crown or a diadem on their heads like the early Bodhisattvas, but a high head-dress made up of thick winding plaits, a feature which also adds to their feminine aspect.

A kind of masculine pendant to these Bodhisattvas may be found among the statues of *bikshus* or monks, executed either as individual *post mortem* portraits or as parts of altar groups (examples of such statues may be seen in the museums in Philadelphia and Boston). They are less conventionalized, less dependent on foreign models and made in closer adherence to actual life. Their heads are portrait-like, their mantles arranged in a more or less natural fashion, thus, in many instances, approaching the small clay statuettes made for the tombs during the T'ang period as well as in earlier times. Some of these portrait statues may indeed be placed on a level with the best Roman sculptures. They are character studies, not so far individualized as Renaissance portraits, but very striking types, observed in actual life. It is also worth noticing how much freer and more plastic the draping of the mantle becomes in these statues. A figure such as the headless monk in the Boston museum might have been made by a Roman artist.

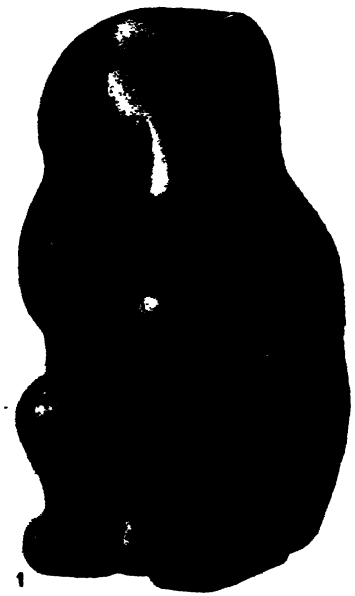


Honan Sculptures.—When we pass from the metropolitan province of Shensi into the adjoining province of Honan we may at once observe that the general character of the sculptures becomes modified. The provincial schools and stylistic differentiations seem on the whole to have become more developed at this time than at earlier epochs; it is now easier to distinguish the provincial currents.

The statues made in Honan, and particularly at the great artistic centre of Lung Men, where the decoration of the caves was continued during the 7th century, are generally more elegant than those originating from Shensi, though not always executed in such perfect technique. Unfortunately, the great majority of the early T'ang sculptures at Lung Men are partly or wholly destroyed—the heads being dispersed all over the world—so that it is now next to impossible to find there complete and good specimens of moderate size; we find them more easily in museums and private collections.

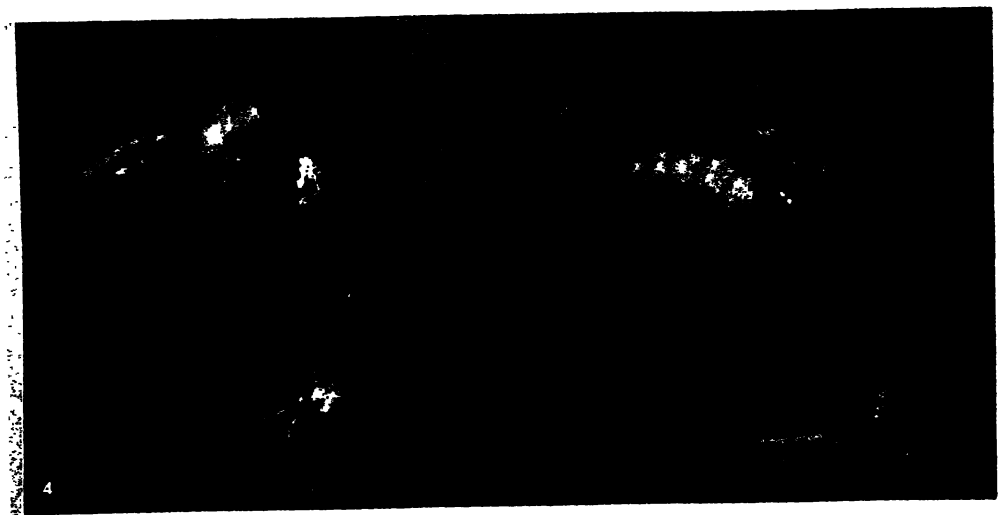
One of the finest examples is a large Bodhisattva statue, originally at Lung Men, but now in private hands in Peking. It may be taken as a representative of a large group of standing Bodhisattvas which all show the Indian influence grafted in Chinese types and shapes, a combination which in this particular instance has led to a perfectly harmonious result. The whole figure from the head-dress down to the feet is dominated by the softly gliding movement of the double S-curve (as in some Gothic madonnas) which would appear almost too accentuated, if it were not so perfectly balanced by the position of the arms. The contemporary Bodhisattvas from Shensi, represented in a similar position, appear quite stiff and hard beside this elegant and yet so dignified figure.

The Vairochana Buddha.—The colossal statues on the open terrace, which rises above the river at Lung Men, reflect in the most monumental form the religious pathos of the fully developed T'ang art. This is true particularly of the central figure, the great Vairochana Buddha; the side figures, two Bodhisattvas and two *bikshus* are decidedly inferior. The hands are destroyed, the lower part of the figure has suffered a great deal, but I doubt whether it ever made a stronger impression than to-day when it rises high and free in the open air over the many surrounding niches in which time and human defilers have played havoc with most of the minor figures. The upper part of this giant is well preserved and more dominating now than ever. Long ages have softened the mantle folds and roughened the surface of the grey limestone which is cracking all over, but they have not spoilt the impression of the plastic form. It may still be felt under the thin garment, a very sensitively modelled form, not a dead mass, though unified in a monumental sense. According to the inscription on the plinth the statue was made about 672–675.



The great power which is here reflected in such a harmonious and well-balanced form finds further dramatic expression in the

PLANS OF THE PRINCIPAL CAVES AT YÜN KANG, LUNG MEN AND T'IEN LUNG SHAN



Dvarapalas which stand at the entrance to the so-called "lion cave." The bestial heads of the figures are amazing and terrible, and even the naked form is by no means represented from a naturalistic point of view, but as a symbol of strength and vigilance. Other Dvarapalas of the same date are sometimes represented in livelier postures, bending sideways or lifting one hand to deal a killing blow to any approaching enemy. The plastic effect is decidedly of a baroque nature, a tendency which is characteristic of the mature T'ang art whenever it leaves the well-trodden path of the traditional religious imagery and ventures on more naturalistic and dramatic representations.

Later T'ien Lung Shan Sculptures.—Another fairly homogeneous local group of T'ang sculpture may be observed in some of the later caves at T'ien Lung Shan where the artistic activity must have been kept up ever since the middle of the 6th century. During all these generations T'ien Lung Shan seems to have remained a special centre of Indian influence. Unfortunately, none of these sculptures is dated, and in some respects they fall outside

CHINESE SCULPTURE: 7TH, 13TH, AND 14TH CENTURIES

1. Standing Bodhisattva, marble statue, end of T'ang period, now in a private collection in the United States
2. Kuanyin Bodhisattva, wooden statue, 13th century
3. Kuanyin Bodhisattva, wooden statue, 13th century
4. Virudhaka, one of the four Lokapâlas (guardians of the universe), relief on the Chü Yung Kuan Gate, Nank'ou, Chih-li, dated 1345
5. Girl playing the lute, marble statue, end of T'ang period

the general stylistic current of T'ang art. Some of them show plastic motives which really did not come into vogue until some time after 700, but this may be due to the fact that they were made under foreign influence. The earliest among these sculptures are remarkably fresh and subtle while the later ones are comparatively heavy and commonplace works. The best specimens of the earlier types are to be seen in caves 6 and 14, while the later ones are found in caves 17, 19, 20 and 21.

The main group on the back wall of cave 6 consists of a Buddha seated cross-legged on a high pedestal accompanied by two side figures, which, however, are almost eaten away by time and running water, but there is a Bodhisattva on the side wall which can still be enjoyed. The figure is seated on a round lotus pedestal with the legs folded but not crossed. He leans toward the right side and turns slightly in the waist, a movement which is accentuated by the turning of the head in the same direction. The left hand is placed on the leg in front as if to give added support to the body and make the free attitude still more restful. The body is entirely bare, except for a jewelled necklace and the narrow scarf which is draped in a diagonal curve from the right shoulder. The ease of the posture in conjunction with the sensitive modelling of the youthful body endow this figure with a sensual charm which is very seldom found in Chinese statues. It would hold its place beside the most exquisite French sculptures of the 18th century and yet it impresses us just as much by its dignity and composure.

A similar artistic conception is expressed in a still ampler form in a Bodhisattva statue in cave 16. The posture of the figure is a kind of *lalitasana* (position of ease). It is seated with the one leg pendant, the other bent crosswise over the seat, but the foot is not placed on the opposite leg. The left elbow is practically touching the knee, as if to support the body which leans over toward the side, turning at the same time slightly in the waist. The movement of the head follows in the opposite direction, producing thus a contraposto effect which, although not very pronounced, serves to bring out the beauty of the ripe body and the supple limbs. It may not have quite the charm of the one noticed above, but it shows an astonishingly free treatment of the mantle, the material being a kind of *draperie mouillée*.

None of the other caves at T'ien Lung Shan contains statues of a corresponding importance, although there are some which reveal the strong Indian influence both in their general shapes and in the treatment of their garments. The heads, which in late years have been knocked off and spread all over the Western world, are sometimes beautiful, though less expressive than the best heads from Lung Men or earlier centres of Buddhist sculpture in China.

Changes in Style.—Similar tendencies toward a freer plastic style may also be observed in contemporary sculptures from Shensi and Chihli. Among them may be seen beautiful Bodhisattvas which not only bend in the waist but also turn on the hips, making thus quite complicated movements, which tend to bring out the beauty and significance of their corporeal form. By these freer postures their likeness to ordinary human beings becomes more striking. They sometimes remind one of the complaint of the philosopher from the end of the T'ang period who said that the artists were losing their reverent attitude toward the religious motives and were representing the Bodhisattvas in the shape of court ladies.

The difference between the religious and the secular motives seems, as a matter of fact, to become less and less important, and one meets with quite realistic *genre* figures not only in clay but also executed on a large scale in stone, very much according to the same formula as the Bodhisattvas. As a good example of this class of work may be mentioned a statue of a young lady (in the Academy of Art in Tokyo) who sits on a bank with crossed legs playing a lute, while a dog and a cat are frolicking at her feet, a statue without any religious pretext, with the same amount of free and elegant realism as we know from the tomb statuettes in clay and from some T'ang paintings. Works of this kind indicate that the sculptors no longer remained satisfied with the purely religious inspiration but turned their attention towards nature and human life. If the evolution had continued along these lines, the plastic arts in China might have become just as expressive and varied in their interpretations of purely artistic problems as Renaissance sculpture in Europe, but the creative power turned more and more from sculpture to painting.

Quite interesting as examples of the new tendencies of style are certain statues made at Ting Chou in Chihli, a centre of sculptural activity which, as we have seen, was important ever since the Northern Wei period. The best of these are surprisingly free and illustrate a new interest in movement and in the full development of the human figure. Among them may be mentioned a large statue of a headless Bodhisattva in the collection of Mrs. J. D. Rockefeller Jr. in New York, which is represented in a forward stride. The figure is composed in a similar way to some early Renaissance statues represented in a walking posture, *e.g.*, St. John the Baptist —and shows the same shortcomings in the stiff limbs and the stilted rhythm, but also the same endeavour to treat the plastic form in the full round.

There are many other statues illustrating this tendency. The most original is perhaps a bare-headed monk who stands turned sideways with hands folded before the chest and head thrown back, looking almost straight upwards (in the collection of General Munthe, Peking). The movement expresses an intense religious devotion, not in the usual restrained and well-balanced form but with the flow of human feeling which leads our thoughts away from the Orient toward the most emotional religious art of Europe, such as we know it from the late Gothic and Baroque periods. The impressionistic treatment of the soft and heavy mantle points in the same direction.

The Post-T'ang Periods.—The production of religious sculpture decreases more and more towards the end of the T'ang period. Very few dated specimens are known from the 9th century, while those from the 8th are quite numerous. During the following periods of the Five Dynasties and the Northern Sung the creative energy of the nation, which in former times, particularly when religious devotion ran high, had been largely directed to the production of sculpture, turned to painting, which now definitely took the lead among the fine arts in China. The change in the relative importance of sculpture and painting is also illustrated by the fact that sculpture responded more and more to the influence of painting, an influence which became evident not only in the new impressionistic tendencies of style but also by the fact that other materials than stone and bronze came into vogue, particularly wood, clay, iron and lacquer-work, and these were usually treated with colour. Many of the new compositions introduced about this time were derived from contemporary paintings. It is true for instance of the very popular Kuanyin Bodhisattvas in the *maharajalila* (posture of royal ease) executed in stone, clay and wood, and it may also be observed in the combination of the figures with backgrounds treated like rocky landscapes or some kind of scenery with trees, buildings, animals and small human beings.

This more or less pictorial kind of sculpture spread all over northern China during the 12th and 13th centuries, when Buddhist art enjoyed a short period of reflorescence, and wooden sculpture particularly reached a high degree of perfection. A great number of wooden statues have in later years been brought from China to various Western collections, *e.g.*, the museums in Philadelphia, Chicago and Toronto which alone contain more such statues than can be mentioned here. The majority of these represent either standing Bodhisattvas in long garments which often take on a fluttering movement toward the feet, or Kuanyins on rocky seats in the *maharajalila* posture. One of the standing figures in Toronto is said to have been dated by a tablet inserted in the figure in the year 1106, while one of the seated Kuanyins, lately belonging to the Ton Ying company in New York, carries an inscription with the date 1168. Similar ones are to be found in the British Museum, in the museums in Boston and Chicago, in the Musée Guimet and Collection Jean Sauphar in Paris, etc.

It is during this period that Kuanyin, the Bodhisattva of Mercy, definitely changes into a feminine being usually represented in a free and elegant form, whether she be seated on a rock by the water in the *maharajalila* posture, as in so many of

these wooden figures, or is standing, bending forward as if lending a listening ear to the invocations of her adorers. The womanly beauty is much more accentuated in these figures than any bodhisattvic qualities. The form has lost all its abstract serenity and become fluttering and emotional, but it is sometimes highly decorative in a new and more limited sense. Many of these figures seem to have been conceived not for a moral purpose, like the old Buddhas and Bodhisattvas, but simply to please the eye and the sentimental longings of the worshippers. Besides these wooden sculptures there are a good many made in stone, particularly series of Arhats, who are usually represented in series of 16 or 18, according to definite types and with more realistic than artistic expression. Interesting series of such Arhats executed in stone may be seen at the Yen Sha Tung and Ling Yen Ssu caves near Hangchow, as well as in the museum at Toronto. They are very uneven in quality and, on the whole, more interesting from an historical than from an artistic point of view.

Yuan Dynasty.—After the establishment of the Yüan dynasty (1280–1368) the position of the fine arts in China, including sculpture, changed considerably. The Mongols brought no new positive inspiration, on the contrary they destroyed more than they built up, except perhaps in the art of war. Art was useful to them only in so far as it could support and glorify the temporal power of the emperor and his generals. The religious attitude of the Yüan emperors was on the whole tolerant, but officialdom was then thoroughly Confucian and the Buddhists were pushed into the background. Taoism seems now to have held its place by the side of Buddhism. The cave sculptures at Hao Tien Kuan, south of T'aiyüan-fu in Shansi, executed at the end of the 13th century, are in this respect very interesting. Some of the compositions illustrating scenes from the life of the Taoist philosopher Pi Yün Ssu, besides a great number of other Immortals, reveal an evident interest in nature as, for instance, the old man on his deathbed; he is represented lying soundly asleep on the Chinese "kang" clad in a long garment. The most successful portions in these grottos are, however, the purely decorative compositions, the low reliefs on the walls representing clouds and phoenixes, and the two guardians at the sides of one of the entrances whose fluttering draperies are arranged in ornamental curves. All these decorative designs are characterized by a buoyancy and a vigour which are hardly to be found in Chinese sculpture of the immediately preceding period. The motives are used for decoration rather than for the expression of purely plastic ideas. The pictorial tendency which characterizes the sculptures of the preceding period is still existent, although it has become coarser and of a more superficial kind. The same stylistic tendencies are also quite noticeable in a number of other sculptures of the same period, such as the four *Lokapalas* (guardians of the world) on the Chü Yung Kuan gate at Nank'ou, executed in 1345, and the Buddhist figures in a niche at Lung Tung Ssu near Tsinan-fu in Shantung, executed in 1318, not to speak of minor detached statues, dated at the beginning of the 14th century.

Ming Period.—When we enter into the Ming period (1368–1644) the dramatic power of expression seems to dry up more and more and the general artistic level is certainly not raised, although the production of Buddhist sculptures goes on with increasing abundance. Among the most popular and common creations of this time may be mentioned, for instance, series of Arhats in iron (good examples of such series are in the museums at Toronto and Gothenburg) which, however, seldom rise above the level of ordinary mass products made according to standard models. Similar motives are also treated in wood and lacquer, sometimes with good decorative effect, though with no more individual characterization. The sculpture of the Ming period is generally at its best when it takes up purely realistic motives instead of the traditional hieratic figures. It may thus become quite enjoyable in minor representations of mourners, musicians or similar *genre*-like motives, presented without any tendency to archaic restraint which otherwise is so apparent in the plastic arts of the Ming.

Summary.—Trying to sum up the general course of development of Chinese sculpture from the 10th to the 15th century in a few words, we have to remember first the comparatively low level of religious sculpture towards the end of the Sung dynasty, particularly after the capital was moved from Kaifêng to Hangchow; secondly, the re-awakening of religious imagery in the northern provinces after the Tartar dynasties had got a firm hold on this part of the country (a flourishing sculptural activity, particularly in wood, developed there in the provinces of Chihli and Shansi); and thirdly, that with the Yüan dynasty a new foreign element appears which perhaps may be called Mongolian and which expresses itself on the one hand in a somewhat dry realism and on the other hand in a whirling linear ornamentation. The religious figures have still some life and expression of their own, though no real spirituality. This development was no longer continued during the Ming period. Whatever creative power may have been left did not turn towards the production of religious sculpture. It is true that a lot of statues, or rather statuettes, in bronze, wood, porcelain and ivory were produced but no great religious works, whether in stone or other materials. The Ming sculptors have given their best in the field of decorative art such as columns, balustrades, and other architectural details, but they created no new types of plastic works, whether religious or secular. They sought their inspiration much more in the imitation of earlier models than in any fresh efforts in the field of sculpture.

CHINGFORD, a municipal borough in the Epping parliamentary Division of Essex, England, 12 mi. N.E. of London by the L.N.E.R. Pop. (1938) 37,510. Area 4.5 sq.mi. It lies between the river Lea and the western outskirts of Epping forest. The church of All Saints has Early English and Perpendicular remains. The half-timbered Queen Elizabeth's, or Fair Mead, hunting lodge is preserved there. Chingford was incorporated in 1938 and adopted a town planning scheme.

CHINGLEPUT, town and district, British India, in the Madras presidency. The town, situated 36 mi. by rail from Madras, and a junction for a branch line to Arkonam, had a population in 1941 of 17,829. With Chandragiri in North Arcot, Chingleput was once the capital of the Vijayanagar kings, after their overthrow by the Mohammedans at Talikota in 1565. In 1639 a chief, subject to these kings, granted to the East India Company the land on which Fort St. George now stands. The fort built by the Vijayanagar kings in the 16th century, which was of strategic importance, was taken by the French in 1751, and retaken in 1752 by Clive, after which it proved invaluable to the British. It withstood Hyder Ali and afforded a refuge to the natives; and in 1780, after the defeat of Colonel W. Baillie, the army of Sir Hector Munro took refuge here. It is now partially ruined. The town is noted for its manufacture of pottery, and carries on a trade in rice. It is the centre of a Scotch Free Church mission, and has a reformatory school.

THE DISTRICT OF CHINGLEPUT surrounds the city of Madras, stretching along the coast for about 115 miles. The administrative headquarters are at Saidapet. Area 3,074 sq.mi. Pop. (1941) 1,823,955. Salt is extensively manufactured along the coast, and fishing carried on. There are cotton and silk mills, tanneries, stone quarries and soapworks.

CHIN HILLS, a constituent hill-group of the mountain arc stretching from the Arakan Yoma northwards to the Patkai hills, between Burma and India. This mountain arc, compressed at either end, has advanced farthest towards the west in the centre

where the long parallel folds are most numerous and the arc broadest. The Chin hills form the highest part of this central stretch. They consist simply of a succession of long narrow troughs and ridges, from 5,000 to 9,000 ft. high, with little flat land either in the valley bottoms or on the ridge tops. There is a marked climatic contrast between the humid tropical conditions of the deeply cut valleys and the cooler temperatures of the ridges. This contrast is reflected in the vegetation. Above 3,000 ft. the tropical forest gives way to oak and pine woods which in turn give way above 7,000 ft. to the rhododendron. A migratory form of agriculture, the *taungya* system, is practised in these hillside woods where the greater part of the population is centred. Clearings are made and the wood burnt for fertilizer. Such clearings are cultivated for two or three years and then abandoned. Bamboo, bracken and elephant grass then spring up with such vigour that natural re-afforestation is impossible. The main crop cultivated by this method is *jowar* millet contrasting with rice in the plains of Lower Burma. Some rice is, however, grown in the Chin hills on the lower slopes on terraces constructed with the help of felled timber.

The north-south trend lines of Indo-China as a whole have permitted the flooding of the region with "Mongoloid" peoples coming down from the north and have hindered east-west movement of both peoples and culture. The Arakan Yoma-Patkai mountain arc, of which the Chin hills form a part, exemplifies these features. It constitutes a frontier zone between Indian and Burmese cultures and its hill-tribes remained independent of British administration until the close of the 19th century. The Chin hills, lying on the Irrawaddy side of the watershed, were eventually occupied to prevent the raids by hill-folk on the plains of Burma. They are now administered primarily with the object of preserving the peace and of building up a sound government on the basis of the tribal system. The substitution of peaceful agriculture for raiding is producing changes in the distribution of population; the defensive hill-sites are being deserted and population is becoming concentrated on the more easily cultivable land. The whole of the southern part of the Arakan Yoma-Patkai mountain arc from the Chin hills southward into the Arakan Yoma is occupied by the Chin peoples who belong to the Southern Mongoloid race group and are linguistically a branch of the Tibeto-Burmans. The Chin hills proper are occupied by only the northern tribes of the Chin peoples. Area of the district 10,377 sq.mi. Population (1941) 186,405. (P. M. R.)

CHINKIANG, former treaty port of China on the south bank of the Yangtze Kiang, 32° 11′ N., 119° 24′ E., 160 mi. above Shanghai and 43 mi. below Nanking. It lies where the north-south route of the Grand canal from Hangchow to Peiping crosses the east-west route of the Yangtze river. So long as the Grand canal, linking the Yangtze delta with the imperial capital, remained an arterial line of communication, Chinkiang retained its significance. But traffic on the Grand canal became after 1850 increasingly local and its function as a north-south link was later usurped by the Tientsin-Pukow (Tsin-Pu) railway, which comes down to the Yangtze opposite Nanking, itself the terminus of a railway from Shanghai.

Chinkiang, although a station on the Shanghai-Nanking railway, had therefore given place to Nanking in the command of the Yangtze crossing. Moreover the port of Chinkiang was experiencing local difficulties through silting. In consequence, while, since the first decade of the 20th century, the trade of neighbouring ports had continued to increase, that of Chinkiang had been arrested.

The port was functioning for a time almost solely as a distributing place of imported goods. In 1926 the excess of imports over exports was in the proportion of 15 to 1. With the fall of Chinkiang into Japanese hands, Dec. 1937, the Japanese controlled the river trade. The population was given as 216,803 in 1937.

CHINO-JAPANESE WAR (1894–95). The causes of this conflict arose out of the immemorial rivalry of China and Japan for influence in Korea. In the 16th century a prolonged war in the peninsula had ended with the failure of Japan to make good her footing on the mainland—a failure brought about largely by lack of naval resources. In more modern times (1875, 1882, 1884) Japan had repeatedly sent expeditions to Korea, and had fostered the growth of a progressive party in Seoul. The difficulties of 1884 were settled between China and Japan by the convention of Tientsin, wherein it was agreed that in the event of future intervention each should inform the other if it were decided to despatch troops to the peninsula. Nine years later the occasion arose. A serious rebellion induced the Korean Government to apply for military assistance from China. Early in June 1894 a small force of Chinese troops was sent to Asan, and Japan, duly informed of this action, replied by furnishing her minister at Seoul with an escort, rapidly following up this step by the despatch of about 5,000 troops under Maj.-Gen. Oshima. A complicated situation thus arose. Chinese troops were present in Korea by the request of the Government to put down rebellion. The Japanese controlled the capital, and declined to recognize Korea as a tributary of China. But they proposed that the two Powers should unite to suppress the disturbance and to inaugurate certain specified reforms. China considered that the measures of reform must be left to Korea herself. The reply was that Japan considered the Government of Korea "lacking in some of the elements which are essential to responsible independence." By the middle of July war had become inevitable unless the Peking Government were willing to abandon all claims over Korea, and as Chinese troops were already in the country by invitation, it was not to be expected that the shadowy suzerainty would be abandoned.

At Seoul the issue was forced by the Japanese minister, who delivered an ultimatum to the Korean Government on July 20. On the 23rd the palace was forcibly occupied. Meanwhile China had despatched about 8,000 troops to the Yalu river. The outbreak of war thus found the Japanese in possession of Seoul and ready to send large forces to Korea, while the Chinese occupied Asan (about 40m. south of the capital) and had a considerable body of troops in Manchuria in addition to those despatched to the Yalu river. To Japan the command of the sea was essential for the secure transport and supply of her troops. Without it the experience of the war of the 16th century would be repeated. China, too, could only utilize overland routes to Korea by submitting to the difficulties and delays entailed.

By the time war was finally declared (August 1), hostilities had already begun. On July 25 Oshima set out from Seoul to attack the Chinese at Asan. On the 29th he won a victory at Sönghwan, but the Chinese commander escaped with a considerable part of his forces by a détour to Ping-Yang (Phyöng-Yang). Meanwhile a portion of the Japanese fleet had encountered some Chinese warships and transports off Phung-Tao, and scored an important success, sinking, amongst other vessels, the transport "Kowshing" (July 25). The loss of more than 1,000 Chinese soldiers in this vessel materially lightened Oshima's task. The intention of the Chinese to crush their enemies between their forces at Asan and Ping-Yang was completely frustrated, and the Japanese obtained control of all southern Korea.

Reinforcements from Japan were now pouring into Korea, and Gen. Nozu, the senior Japanese officer present, soon found himself in a position to move on Ping-Yang. Three columns converged upon the place on Sept. 15 and carried it after severe fighting.

Nearly all the troops on either side had been conveyed to the scene of war by sea, though the decisive contest for sea supremacy was still to be fought. The Chinese admiral Ting with the Northern squadron (which alone took part in the war) had hitherto remained inactive in Wei-hai-wei, and on the other side Vice-Admiral Ito's fleet had not directly interfered with the hostile transports which were reinforcing the troops on the Yalu. But two days after the battle of Ping-Yang, Ting, who had conveyed a large body of troops to the mouth of the Yalu, encountered the Japanese fleet on his return journey off Hai-Yang-Tao on Sept 17. The heavy battleships "Chên-Yuen" and "Ting-Yuen" constituted the strongest element of the Chinese squadron, for the Japanese, superior as they were in every other factor of success, had no vessels which could compare with these in the matter of protection. Ting advanced in a long irregular line abreast; the battleships in the centre, the lighter vessels on the wings. Ito's fast cruisers steamed in line ahead against the Chinese right wing,

crushing their weaker opponents with their fire. In the end the Chinese fleet was defeated and scattered, but the two heavy battleships drew off without serious injury. This battle of the Yalu gave Japan command of the sea, but Ito continued to act with great caution. The remnants of the vanquished fleet took refuge in Port Arthur, whence after repairs Ting proceeded to Wei-hai-wei.

The victory of Ping-Yang had cleared Korea of the Chinese troops, but on the lower Yalu—their own frontier—large forces threatened a second advance. Marshal Yamagata therefore took the offensive with his I. Army, and on Oct. 24 and 25, under great difficulties—though without serious opposition from the enemy—forced the passage of the river and occupied Chiu-lien-chêng. Part of the Chinese force retired to the north-east, part to Fêng-hwang-chêng and Hsiu-yuen. The Japanese I. Army advanced several columns towards the mountains of Manchuria to secure its conquests and prepare for a future advance. Gen. Tachimi's brigade, skirmishing with the enemy on the Moukden and Liao-Yang roads, found the Chinese in force. A simultaneous forward move by both sides led to the action of Tsao-ho-ku (Nov. 30), after which both sides withdrew—the Chinese to the line of the mountains covering Hai-chêng, Liao-Yang and Moukden, with the Tatar general Ikotenga's force 14,000 strong, on the Japanese right north-east of Fêng-hwang-chêng; and the Japanese to Chiu-lien-chêng, Takushan and Hsiu-yuen. The difficulties of supply in the hills were almost insurmountable, and no serious advance was intended by the Japanese until Jan. 1895, when it was to be made in co-operation with the II. Army. This army, under Marshal Oyama, had been formed in September and at first sent to Chemulpho as a support to the forces under Yamagata; but its chief task was the siege and capture of the Chinese fortress, dockyard and arsenal of Port Arthur.

The Liao-Tong peninsula was guarded by the walled city of Kin-chow and the forts of Ta-lien-wan (Dalny under the Russian régime, and Dairen under the Japanese) as well as the fortifications around Port Arthur itself. On Oct. 24 the disembarkation of the II. Army began near Pi-tse-wo, and the successive columns of the Japanese gradually moved towards Kin-chow, which was carried without difficulty. Even less resistance was offered by the modern forts of Ta-lien-wan. The Japanese now held a good harbour within a few miles of the main fortress. Here they landed siege artillery, and on Nov. 17 the advance was resumed. The attack was made on the 19th at dawn. Yamaji's division (Nogi's and Nishi's brigades), after a trying night march, assaulted and carried the western defences and moved upon the town. Hasegawa in the centre, as soon as Yamaji began to appear in rear of his opponents in the northern forts, pushed home his attack with equal success, and by 3 P.M. practically all resistance was at an end. The Japanese paid for this important success with but 423 casualties. Meanwhile the Chinese general Sung, who had marched from Hai-chêng to engage the II. Army, appeared before Kin-chow, where he received on the 22nd a severe repulse at the hands of the Japanese garrison. Soon after this overtures of peace were made by China; but her envoy, a foreigner unfurnished with credentials, was not received by the Tokyo Government.

The Japanese I. Army (now under Gen. Nozu) prepared, in spite of the season, to move across the mountains, and on Dec. 3 Gen. Katsura left Antung for Hai-chêng, which was safely occupied on Dec. 13. In the meantime Tachimi had moved northward from Fêng-hwang-chêng in order to distract the attention of the Chinese from Hai-chêng, and there were some small engagements between this force and that of Ikotenga, who ultimately retired beyond the mountains to Liao-Yang. Sung had already left Kai-ping to secure Hai-chêng when he heard of the fall of that place; his communications with Ikotenga being now severed, he swerved to the north-west and established a new base at Niu-chwang. Once on his new line Sung moved upon Hai-chêng. As it was essential that he should be prevented from joining forces with Ikotenga, Gen. Katsura marched out of Hai-chêng to fight him. At Kang-wang-tsai (Dec. 19) the Chinese displayed unusual steadiness, and it cost the Japanese some 343 casualties to dislodge the enemy. The victors returned to Hai-chêng exhausted with their efforts, but secure from attack for some time to come. The advanced troops of the II. Army (Nogi's brigade) were now ready to advance, and only the Kai-ping garrison barred their junction with Katsura. At Kai-ping (Jan. 10) the resistance of the Chinese was almost as steady as at Kang-wang-tsai, and the Japanese lost 300 killed and wounded in their successful attack. In neither of these actions was the defeated force routed, nor did it retire very far. On Jan. 17 and again on the 22nd Ikotenga attacked Hai-chêng from the north, but was repulsed.

Meanwhile the II. Army, still under Oyama, had undertaken operations against Wei-hai-wei, the second great fortress and dockyard of northern China; and it was hoped that both armies would accomplish their present tasks in time to advance in the summer against Peking itself. On Jan. 18 a naval demonstration was made at Têng-chow-fu, 70m. west of Wei-hai-wei, and on the 19th the Japanese began their disembarkation at Yung-chêng Bay, about 12m. from Wei-hai-wei. The landing was scarcely opposed, and on the 26th the Japanese advance was begun. The south-eastern defences of Wei-hai-wei harbour were carried by the 6th Division, whilst the 2nd Division reached the inner waters of the bay, driving the Chinese before them. The fleet under Ito co-operated effectively. On the night of Feb. 4–5 the Chinese squadron in harbour was attacked by ten torpedo boats. Two boats were lost, but the armour-clad "Ting-Yuen" was sunk. On the following night a second attack was made, and three more vessels were sunk. On the 9th the "Chên-Yuen" was sunk by the guns in one of the captured forts. On the 12th Admiral Ting wrote to Admiral Ito offering to surrender, and then took poison, other officers following his example. Wei-hai-wei was then dismantled by the Japanese and the II. Army concentrated at Port Arthur for the advance on Peking.

While this campaign was in progress the Chinese despatched a second peace mission, also with defective credentials. The Japanese declined to treat, and the mission returned to China. In February the Chinese made further unsuccessful attacks on Hai-chêng. Yamaji near Kai-ping fought a severe action on Feb 21, 22 and 23, at Taping-shan against a part of Sung's army under Gen. Ma-yu-kun. This action was fought with 2ft. of snow on the ground, the thermometer registering zero F, and no less than 1,500 cases of frost-bite were reported. It was the intention of Gen. Nozu, after freeing the Hai-chêng garrison from Ikotenga, to seize Niu-chwang port. Two divisions converged on An-shan-chan, and the Chinese, threatened in front and flank, retired to Liao-Yang. The Japanese then moved on Niu-chwang, and Yamaji's 1st Division at Kai-ping joined in the advance. The column from An-shan-chan stormed Niu-chwang, which was obstinately defended, and cost the stormers nearly 400 men. All three divisions converged on Niu-chwang port (Ying-kow), and the final engagement took place at Tien-chwang-tai, which was captured on March 9. The Chinese forces in Manchuria being thoroughly broken and dispersed, there was nothing to prevent the Japanese from proceeding to the occupation of Peking, since they could, after the break-up of the ice, land and supply large forces at Shan-hai-kwan, within 170m. of the capital. Seven divisions were at Port Arthur ready to embark when negotiations were reopened. Li Hung-Chang proceeded to Shimonoseki, where the treaty was signed on April 17, 1895. An expedition was sent towards the end of March to the Pescadores, and later the Imperial Guard Division was sent to Formosa.

It is impossible to estimate the Chinese losses in the war. The Japanese lost 4,177 men by death in action or by sickness, and 56,862 were wounded or disabled by sickness, exclusive of the losses in the Formosa and Pescadores expeditions. Nearly two-thirds of these losses were incurred by the I. Army in the trying winter campaign in Manchuria.

La Guerre sino-japonaise* (Paris and Limoges)

CHINON, a town of western France, capital of an arrondissement in the department of Indre-et-Loire, on the bank of the Vienne, 32 m. S.W. of Tours. Pop. (1936) 4,511. It lies under a rocky height crowned by ruins of the famous castle, its narrow, winding streets containing many turreted houses of the 15th and 16th centuries. Chinon (Caïno) existed before the Roman occupation of Gaul, and was from early times an important fortress. It was occupied by the Visigoths, and subsequently, after forming part of the royal domain, came to the counts of Touraine and from them to the counts of Anjou, in 1044. In the next century it passed to Henry II. of England, who died there, but it was won back to France by Philip Augustus in 1204, after a year's siege. Of its oldest church, the Romanesque St. Mexme, only the façade and nave are left. The church of St. Etienne dates from the 15th century, that of St. Maurice from the 12th, 15th and 16th centuries. The castle, which has undergone considerable modern restoration, consists of three separate strongholds. That to the east, the Château de St. Georges, built by Henry II. of England, has almost vanished, only the foundation of the outer wall remaining. The Château du Milieu (11th to 15th centuries) comprises the keep, the Pavillon de l'Horloge and the Grand Logis, where the first meeting between Joan of Arc and Charles VII. took place. Of the Château du Coudray, which is separated by a moat from the Château du Milieu, the chief remains are the Tour du Moulin (10th century) and two later towers. A statue of Rabelais, who was born in the vicinity of the town, stands on the river-quay. Basket and rope manufacture, tanning and cooperage are among the industries.

CHINOOK. This important American Indian people held Columbia river from the mouth to the Dalles, and adjacent territory. Their culture was a localized form of the North Pacific Coast (*q.v.*) type, with plank houses, good canoes, trade, slavery, potlatch distributions of property, but without secret societies or totemic art. The language is distinctive, and a selection of words from it, much simplified phonetically and the grammar wholly done away with, forms the basis of the Chinook jargon. This trade language contains also French, English, Nutka and other Indian ingredients, and prevails from Oregon to Alaska. The Chinook were organized by settlements rather than tribes; some of their divisions are known as Clatsop, Wasco and Wishram. Estimated at 16,000 in 1805, they decreased (from disease) to a twentieth in the next 50 years, and now number perhaps 200–300, known under different names on several reservations containing ethnic mixtures.

See Lewis and Clark, *Original Journals* (1904); F. Boas, *Bur. Am. Ethn.* Bull. 20 (1895); E. Sapir, *Publ. Am. Ethn. Soc.*, vol. ii. (1909). (A. L. K.)

CHINOOK, the name given to a wind which blows from west or north over the Rocky Mountains, where it descends as a dry wind, warm in winter and cool in summer. It is due to a cyclone passing northward, and continues for a few hours to several days. It moderates the climate of the eastern Rockies, the snow melting quickly on account of its warmth and vanishing on account of its dryness, so that it is said to "lick up" the snow from the slopes.

CHINQUAPIN, the name given to several North American shrubs or small trees belonging to the genus *Castanea* of the Fagaceae (beech family). The most important of these is *C. pumila*, a shrub or small tree found chiefly in dry soils from New Jersey to northern Florida and westward to southwestern Missouri and eastern Texas. In Arkansas and Texas, where it attains its best development, it occasionally reaches a height of 45 ft. and a diameter of 30 in. It is closely related to the chestnut, *C. dentata*, from which it differs in its much smaller leaves, which are white-woolly beneath, and its usually solitary nut, which like that of the chestnut is very sweet and edible.

On the Pacific slope the name chinquapin is given to two species of *Castanopsis*, a genus closely allied to *Castanea*. Golden chinquapin (*Castanopsis chrysophylla*) found from southern Washington to southern California, is a magnificent tree which occasionally attains a height of 150 ft. and a trunk diameter of 8 ft. The lance-shaped evergreen leaves, 3 to 5 in. long, are clothed beneath with minute golden-yellow persistent scales. The fruit is similar to that of the chestnut and contains one or two hard-shelled nuts with a sweet kernel. The wood is reddish-brown, straight grained, easily worked and takes an excellent finish, yet it is not extensively utilized. The bark, although devoid

CHINQUAPIN. BRANCH (LEFT) SHOWING SPINY BURR AND SOLITARY NUT; BRANCH (RIGHT) WITH MALE FLOWERS

of tannin, is sometimes used to adulterate that of the tanoak (*Lithocarpus densiflorus*), with which it is often associated in the forest. Bush chinquapin (*C. sempervirens*) is a small spreading shrub of dry mountain slopes in California. Some authorities regard it as a variety of the golden chinquapin. (E. S. Hr.)

CHINSURA, a town of British India, on the Hooghly river, 24m. above Calcutta, formerly the principal Dutch settlement in Bengal. The Dutch erected a fortified factory here in 1656. In 1759 a British force under Col. Forde was attacked by the garrison of Chinsura on its march to Chandernagore, but in less than half an hour the Dutch were entirely routed. Chinsura was taken by the British in 1781 on the outbreak of war with Holland and restored to the Dutch in 1783. Again, in 1795, during the Napoleonic wars, the settlement was occupied by a British garrison. At the peace of 1814 it was a second time restored to the Dutch. It was among the cessions in India made by the king of the Netherlands in 1825 in exchange for the British possessions in Sumatra. The Dutch church, commissioner's house, and cemetery (extended since 1825) are memorials of Dutch rule. Chinsura is included in the Hooghly-Chinsura municipality (pop. [1941] 49,081), and contains the Hooghly college.

CHINTZ, a word derived from the Hindu *chint*, spotted or variegated. This name was given to a kind of stained or painted calico produced in India. It is now applied to a highly glazed printed calico, commonly made in several colours on a light ground and used for bed hangings, covering furniture, etc.

CHINWANGTAO, 39° 56′ N., 119° 38′ E., former treaty port on the shores of the Gulf of Liaotung in northeast China; the port was created by, and the harbour is the property of, the Kailan Mining administration, which works the Kaiping coalfield some 100 miles away. Export trade originated almost entirely from the coalfield and comprised not only coal but also coke, firebricks and cement manufactured at Tangshan, the new industrial town on the coalfield. Chinwangtao had also the largest glass factory in China. As it was the only ice-free port on the shallow gulf of Liaotung Chinwangtao had developed as a winter out-port to Tientsin, and to a lesser extent to Newchwang as well. This out-port function did not remain quite so important as at the beginning of the 20th century. The navigation of the Hai-ho could be kept open whenever the winds were off-shore and much of the trade that formerly went through Newchwang had since the advent of the Japanese been diverted through the ice-free Dairen. The port was first opened to foreign trade in 1901. After the Manchurian incident the Japanese pressure led to intensive smuggling of Japanese goods into North China largely through Chinwangtao. With establishment of the East Hopei autonomous puppet regime, Dec. 1935, smuggling continued disguised as a special tariff. After the Japanese invasion trade increased from $1,024,120 (U.S.) to $21,399,938 for import and from $2,099,392

to $4,324,975 for export, 1936–39, with Manchuria and Japan holding the largest percentages. Pop. 20,020.

CHIOGGIA, a town and episcopal see of Venetia, Italy, in the province of Venice, from which it is 18½ mi. S. by sea. Pop. (1936) 23,577 (town), 42,569 (commune). Chioggia is inhabited mostly by fishermen, and is situated upon an island at the south end of the lagoons. It is traversed by one main canal, La Vena, and has some picturesque and interesting mediaeval buildings. The peculiar dialect and customs of the inhabitants still survive to some extent. It is probably the Roman Portus Aedro, though its name is derived from the Roman Fossa Claudia, a canalized estuary which with the two mouths of the Meduacus (Brenta) went to form the harbour. In A.D. 672 it entered the league of the cities of the lagoons, and recognized the authority of the doge. In 809 it was almost destroyed by Pippin, but in 1110 was made a city, remaining subject to Venice. Chioggia is connected by rail with Rovigo, 35 mi. to the southwest. (X.)

The Naval War of Chioggia (1378–1380).—The naval war of 1378–80, carried on by the Genoese and their allies against Venice, is of exceptional interest as one in which a superior naval power, having suffered disaster in home waters, was yet able to win by holding out till its squadrons in distant seas could be recalled for its defence.

Venice was mainly concerned for the safety of her trading stations in the Levant and the Black sea. The more powerful of her two fleets was sent to the eastern Mediterranean under Carlo Zeno, and the smaller to operate against the Genoese in the western Mediterranean, under Vettor Pisani. The possessions of Venice on the mainland were assailed by the lord of Carrara and the Hungarians, but this danger seemed trifling so long as Venice could keep the sea open to her trade.

At first she was entirely successful. While Carlo Zeno harassed the Genoese stations in the Levant, Pisani brought one of their squadrons to action in May, 1378, to the south of the Tiber, and defeated it. If Pisani had sailed direct to Genoa itself, which was thrown into a panic, he might have dictated peace, but he thought his squadron too weak, and followed the Genoese galleys which had fled to Famagusta in Cyprus. During the summer of 1378 he was employed partly off Cyprus, but mainly in taking and capturing the Istrian and Dalmatian towns which supported the Hungarians. He was ordered to winter on the coast of Istria, where his crews suffered from exposure and disease. Genoa now decided to attack Venice at home while the best of her ships were absent with Carlo Zeno, and sent a strong fleet under Luciano Doria. Pisani had been reinforced early in the spring of 1379, but when he was sighted by the Genoese fleet off Pola on May 7, he was slightly out-numbered, and his crews were still weak. He would have preferred to avoid action and to threaten the Genoese fleet from his base on the Istrian coast, but he was forced into battle by the Senate, and was defeated with great loss. On the other hand Luciano Doria himself was killed, and the Genoese, who had suffered severely, did not at once follow up their success. On the arrival of Pietro Doria, with reinforcements, they appeared off the Lido, the outer barrier of the lagoon of Venice, and in July began combined operations against Chioggia, co-operating with the Carrarese and the Hungarians. The Venetians had closed the passages through the outer banks except at the southern end, at the island of Brondolo, and the town of Chioggia. The barrier here approaches close to the mainland, and the position facilitated the co-operation of the allies; but Chioggia is some distance from Venice, which could only be reached across the lagoon, where the Venetians had taken up the buoys and had a light squadron. The allies, after occupying the island of Brondolo, attacked, and took the town of Chioggia on Aug. 13.

There was nothing now to prevent them from advancing on Venice itself except the difficult navigation of the lagoon. The Senate applied for peace, but the Genoese offered impossible terms. Pisani, who had been imprisoned after the defeat at Pola, was released and named commander-in-chief. The heavy Genoese vessels were much hampered by the intricate passages through the lagoon, and by using his own local knowledge, Pisani completely turned the tables on the invaders by a succession of night attacks, during which he sank vessels in the canals leading through the lagoon to Venice, and in the fairways leading from Chioggia to the open sea. The Genoese were thus blockaded, Pisani having stationed his galleys in the open sea outside Brondolo. The Venetians themselves were in great distress; Carlo Zeno had long since been ordered home, but he was delayed by the difficulty of communication under 14th century conditions, and the besiegers of Chioggia were at the end of their strength when his fleet reached Brondolo on Jan. 1, 1380. The Genoese held out in the hope of relief from home, but it was not until May, 1380, that Matteo Maruffo arrived with reinforcements. By this time the Venetians had recovered the island, and their fleet occupied a fortified anchorage so that Maruffo could do nothing, and on June 24, 1380, the Genoese defenders of Chioggia surrendered. Venice, being now safe at home, recovered the command of the sea, and before the close of the year was able to make peace as a conqueror.

CHIOS, an island on the west coast of Asia Minor (ancient Greek *Chios*) about 30 mi. long from north to south, and from 8 to 15 mi. broad. Population, 75,680. The north end is mountainous with steep coasts; southwards there is open country, and great fertility. The capital, Chios, on the east coast, has a small safe harbour, and mediaeval fortifications. Population, 22,122. The climate is healthy; oranges, olives and even palms grow freely; the figs were famous in antiquity, but wine and gum mastic have always been the principal products. The latter, collected from a wild shrub, gives flavour and name to a popular Greek liqueur (*masticha*). Antimony, calamine and marble are worked; there is a tanning industry, and considerable coasting trade.

There are few remains of ancient Chios (on the same site as the modern); traces of a theatre and a temple of Athena Poliuchus; and about 6 m. N. of the city the curious "School of Homer," a sanctuary of Cybele, with altar and figure of the goddess with two lions, in the native rock of a hill-top. On the west coast is a rich monastery with a church founded by Constantine IX. Monomachus (1042–54). In antiquity Chios was famous for its school of epic poets, the Homeridae, who claimed descent from Homer, and probably did much to popularize the *Iliad* and *Odyssey* in early Greece.

To Glaucus of Chios was ascribed the invention of iron-welding, early in the seventh century B.C., and his masterpiece, the support of a large bowl, was shown at Delphi: for his place in ancient art and craftsmanship *see* J. G. Frazer *Pausanias*: note on x. 16. 1. (vol. v. pp. 313–4); and for the beautiful and instructive coinage, P. Gardner, *History of Greek Coinage* (index) and the *British Museum Catalogue* (*s.v.*).

The early history of Chios is obscure. There were Greek legends of Leleges, Pelasgi from Thessaly, a Cretan foundation "in the days of Rhadamanthus" (13th century), and of eventual colonization by Ionians from Attica four generations later. Early kings and tyrants are little more than names, but the long friendship with Miletus is significant and determined the hostility of Chios to its neighbours, Phocaea, Erythrae and Samos. The Chian colony at Maroneia on the coast of Thrace reinforced the wine-trade of the mother city. Like Miletus, Chios in 546 submitted to Cyrus as eagerly as Phocaea resisted him. When Miletus revolted, 100 Chian ships joined in offering desperate opposition at Lade (494). Persian reprisals were severe, and temporarily successful, for Chian ships, under the tyrant Strattis, served in the Persian fleet at Salamis. But in 479 Chios joined the Delian League and long remained a firm ally of the Athenians, retaining political independence and a navy of its own. But in 413 the island revolted, and was not recaptured. After the Peloponnesian War it renewed the Athenian alliance, but in 357 again seceded. It was reputed one of the best-governed states in Greece, for although it was governed alternately by oligarchs and democrats neither party persecuted the other severely. Late in the 4th century, however, civil dissension left it a prey to Idrieus, the dynast of Caria (346), and to the Persian admiral Memnon (333). During the Hellenistic age Chios retained its independence, supported the

Romans in their Eastern wars, and was made a "free and allied state." Under Roman and Byzantine rule industry and commerce were undisturbed, its chief export at this time being the "Arvisian wine," of the north-west coast (*Ariusia*). After temporary occupations by the Seljuk Turks (1089–1092) and by the Venetians (1124–1125, 1172, 1204–1225), it was given in fief to the Genoese family of Zaccaria, and in 1346 passed definitely into the hands of a Genoese *maona*, or trading company, which was organized in 1362 under the name of "the Giustiniani," and alone exploited the mastic trade; but the Greeks were allowed to retain their rights of self-government and continued to exercise their industries. In 1415 the Genoese became a tributary to the Ottomans and, in spite of occasional secessions which brought severe punishment (1453, 1479), the rule of the Giustiniani was not abolished till 1566. But capture and reconquest from the Florentines (1595) and the Venetians (1694–1695), greatly reduced the number of the Latins and wrecked its prosperity. Worst of all were the massacres of 1822, which followed upon an attack by Greek insurgents against the will of the natives. Many survivors fled to Syra (*q.v.*) and founded its prosperous carrying trade. But the island's natural resources made its recovery sure, and its efficient and peaceable inhabitants passed quietly from Turkish to Greek rule during the Balkan War of 1912.

CHIPMUNK (TAMIAS STRIATUS), FOUND IN EASTERN UNITED STATES AND CANADA

CHIPMUNK, the name for small striped ground squirrels (*Tamias striatus* and numerous species of the genus *Eutamias*) found in North America and eastern Asia. They are 5 or 6 in. long, with a tail about 4 in., reddish or grayish brown in colour.

(J. E. HL.)

CHIPPENDALE, THOMAS (*c.* 1718–1779), the most famous of English cabinet-makers, was the son of John Chippendale, a joiner of Otley, Yorkshire. He was baptised at Otley on June 5, 1718. The materials for the biography of Chippendale are scanty, but it is known that he came to London when he was about 20, and at the end of 1749 established himself in Conduit court, Long Acre, whence in 1753 he removed to No. 60, St. Martin's lane, which with the addition of the adjoining three houses remained his factory for the rest of his life.

It has always been exceedingly difficult to distinguish the work executed in Chippendale's factory and under his own eye from that of the many copyists and adapters who throughout the second half of the 18th century plundered remorselessly. Apart from his published designs, many of which were probably never made up, we have to depend upon the very few instances in which his original accounts earmark work as unquestionably his. For Claydon house, in Buckinghamshire, he executed much decorative work, and the best judges are satisfied that the Chinese bedroom there was designed by him. At Harewood house, in Yorkshire, we are on firmer ground. The house was furnished between 1765 and 1771, and both Robert Adam and Chippendale were employed upon it. Indeed, there is unmistakable evidence to show that certain work, so closely characteristic of the Adams that it might have been assigned to them without hesitation, was actually produced by Chippendale, whose bills for this Adam work are still preserved. For Nostell Priory, Yorkshire he made a quantity of fine furniture in 1766, the bills for which are also in existence there. Stourhead, the famous house of the Hoares in Wiltshire, contains much undoubted Chippendale furniture, which may, however, be the work of his son Thomas Chippendale II.; at Rowton castle Shropshire, Chippendale's bills as well as ' is works still exist.

Our other main source of information is *The Gentleman and Cabinet Maker's Director*, which was published by Thomas Chippendale in 1754. This folio, the most important collection of furniture designs issued up to that time in England, contains 160 engraved plates, and the list of subscribers indicates that the author had acquired a large and distinguished body of customers. There was a second edition in 1759, and a third in 1762.

The *Director* contains examples of each of the manners which Chippendale practised. Occasionally we find in one piece of furniture a combination of the three styles which he most affected at different periods (Louis XV., Chinese and Gothic) and it cannot be said that the result is as incongruous as might have been expected. Some of his most elegant and attractive work is derived directly from the French.

The primary characteristic of his furniture is solidity, but it is a solidity which rarely becomes heaviness. Even in apparently slight work, such as the ribbon-backed chair, construction is always the first consideration. It is indeed in the chair that Chippendale is seen at his best and most characteristic. From his hand, or his pencil, we have a great variety of chairs, which, although differing extensively in detail, may be roughly arranged in three or four groups, which it would sometimes be rash to attempt to date. He introduced the cabriole leg, which, despite its antiquity, came immediately from Holland; the claw and ball foot of ancient Oriental use; the straight, square, uncompromising early Georgian leg; the carved latticework Chinese leg; the pseudo-Chinese leg; the fretwork leg, which was supposed to be in the best Gothic taste; the inelegant rococo leg with the curled or hoofed foot; and even occasionally the spade foot. His chair-backs were very various. His efforts in Gothic often took the form of the tracery of a church window, or even of an ovalled rose window. His Chinese backs were distinctly geometrical, and from them he would seem to have derived some of the inspiration for the frets of the glazed bookcases and cabinets which were among his most agreeable work. The most attractive feature of Chippendale's most artistic chairs (derived from Louis Quinze models) is the back, which, speaking generally, is the most elegant and pleasing thing that has ever been done in furniture. He took the old solid or slightly pierced back, and cut it up into a light openwork design exquisitely carved (for Chippendale was a carver before everything) in a vast variety of designs ranging from the elaborate and extremely elegant ribbon back, to a comparatively plain but highly effective splat. His armchairs, however, often had solid or stuffed backs. Next to his chairs, Chippendale was most successful with settees, which almost invariably took the shape of two or three conjoined chairs, the arms, backs and legs identical with those which he used for single seats. He was likewise a prolific designer and maker of bookcases, cabinets and escritoires with doors glazed with fretwork divisions, cases for long clocks, and a great number of tables, some of them with a remarkable degree of Gallic grace. He was especially successful in designing small tables with fretwork galleries for the display of china. His mirrors, which were often in the Chinese taste or extravagantly rococo, are remarkable and characteristic. Some of Chippendale's most graceful work was lavished upon the woodwork of the lighter, more refined and less monumental four-poster. His claims to distinction are summed up in the fact that his name has by general consent been attached to the most splendid period of English furniture.

Chippendale was buried on Nov. 13, 1779, at the church of St. Martin-in-the-Fields. Of his 11 children, THOMAS CHIPPENDALE II. succeeded to the business of his father and grandfather, and for some years the firm traded under the style of Chippendale and Haig. The factory remained in St. Martin's lane, but in 1814 an additional shop was opened at No. 57, Haymarket, whence it was in 1821 removed to 42, Jermyn street. Like his father, Thomas Chippendale II. was a member of the Society of Arts; and he is known to have exhibited five pictures at the Royal Academy between 1784 and 1801. He died at the end of 1822 or the beginning of 1823.

See Oliver Brackett *Thomas Chippendale, a Study of his Life, Work and Influence* (1924).

CHIPPENHAM, market town and municipal borough in the Chippenham parliamentary division of Wiltshire, England, 94 mi. W. of London by the G.W.R. on the south side of the Upper Avon. Pop. (1938) 10,120. Area 1.9 sq.mi. St. Andrew's church, originally 12th century Norman, has been enlarged in different styles. Chippenham (*Chepeham, Chippeham*) was the site of a royal residence where, in 853, Aethelwulf celebrated the marriage of his daughter Aethelswitha with Burgred, king of Mercia. The town figured prominently in the Danish invasion of the 9th century, and in 933 was the meeting-place of the witan. In the Domesday survey Chippenham appears as a Crown manor. The town was governed by a bailiff in the reign of Edward I; it was incorporated in 1553, but in 1685 received a new charter which was soon abandoned in favour of the original grant. The derivation of Chippenham from *cyppan,* to buy, implies that the town possessed a market in Saxon times. The neighbouring Cotswold hills preserve many relics of early man, and their grasslands produced the sheep which gave Chippenham its fame as a woollen centre from the 16th century. On the decline of this trade the grain and cheese markets developed. Condensed-milk making, bacon curing and engineering are carried on.

The town sent two members to parliament until 1867, and one until 1885.

CHIPPEWA. The Canadian branch of the Chippewa, one of the largest tribes north of Mexico, lives in the woodlands north and west of Lake Superior. Their culture was typical in many respects of the central Algonquians. Moose, deer, beaver and rabbits were snared or killed with arrows; wild-fowl were shot or clubbed, and fish were speared or taken with hook and line. Wild rice was collected as a staple food in the vicinity of Lake Superior; maple sugar was manufactured, and nuts, berries and edible roots are still gathered in large quantities. In their search for game the Chippewa travel long distances, by canoe in summer, or in winter on snow-shoes, dragging their goods on toboggans. These wanderings, however, usually lead back to semi-permanent settlements, where formerly bark houses were used in warm weather, and oval, rush-covered lodges in winter. In pre-Columbian days, utensils were almost entirely of wood or bark, basketry being weakly developed. Clothing was of skins, while bags, belts and garters were woven on heddle looms out of bark or wild hemp fibre. Expert artificers in wood, Chippewa stone work was limited to arrow points and a few tools, while native copper, mined near Lake Superior, was pounded into serviceable shapes.

BY COURTESY OF THE SMITHSONIAN INSTITUTION

CHIPPEWA INDIAN, IN HIS TRIBAL DRESS

Politically, there is no Chippewa "tribe," since the numerous sub-divisions have no single, central authority. Each inhabits a certain locality, and the members enter into definite relations with one another. There is an ill-defined kind of council, consisting of practically all the males of the community, which elects a chief, whose powers are even more shadowy than those of the body that selects him. Social divisions are more definite, since, in addition to the family, there are exogamic patrilineal clans of a totemic nature. Individual ownership of material objects prevails, but land was probably held, in former times, by groups of kindred.

The Chippewa have firm belief in a cosmic force animating all nature which frequently manifests itself in animals, mythical or real. Like their eastern kinsmen, the concept of a guardian spirit was important, and shamanism with conjuring flourished. Entry to the next world depended largely upon membership in the *Midéwiwin,* "Great Medicine Society," a secret organization entered after elaborate initiation. Symbolic pictographs drawn upon bark were perhaps originally connected with this society. (See *Handbook of the American Indian,* 1906.)

CHIPPEWA FALLS, a city of northwestern Wisconsin, U.S.A., on the Chippewa river, 100 mi. E. of St. Paul, the county seat of Chippewa county. It is on federal highway 53, and is served by the Chicago and North Western, the Chicago, Milwaukee, St. Paul and Pacific and the Soo Line railways. The population in 1950 was 11,072. The city has machine shops and a packing plant, and its manufactures include woollen goods, shoes, gloves, pumps, sashes and doors, milk products and cement silos. The first settlement was made in 1837. The city was chartered in 1870.

CHIPPING CAMPDEN, market town, Gloucestershire, England, 29 mi. N.E. from Gloucester by the G.W.R. Pop. (1931) 1,645. It is situated toward the north of the Cotswold hills. A ruined 16th century manor house, some almshouses and the church complete a picturesque group of buildings. The house of William Grevel (d. 1401), a great wool merchant, is noteworthy.

Apart from a mediaeval tradition that a conference of Saxon kings was held there, the earliest record of Campden (*Campedene*) is in Domesday, when earl Hugh held it. The manor passed in 1173 to Hugh de Gondeville, and about 1204 to Ralph, earl of Chester. These lords granted charters which are known from a confirmation dated 1247. In 1605 Campedene was incorporated, but was never represented in parliament. The corporation was abolished in 1885. Camden speaks of the town as a market famous for stockings, a relic of its mediaeval importance as a mart for wool which gave it the name of Chipping.

CHIPPING NORTON, municipal borough, Oxfordshire, England, 16 mi. N.W. of Oxford by a branch of the G.W.R. Pop. (1938) 3,369. It lies on the steep flank of a hill, and consists mainly of one very wide street. Chipping Norton (*Chepyngnorton*) was of some importance in Saxon times. At the Domesday survey it was held by Ernulf de Hesding and assessed at 15 hides with three mills. It returned two members to parliament as a borough in 1302 and 1304–1305, but was not represented after this date. Fairs were granted in 1205 to William Fitz-Alan and in 1276 to Roger, earl of March. In the reign of Henry VI the market was held on Wednesday, and a fair was held at the Translation of St. Thomas Becket. James I annulled the former two fairs, and granted others. He also granted the first and only charter of incorporation. The church of St. Mary the Virgin on the lower slope is a fine building in the Decorated and Perpendicular styles. The trade is still mainly agricultural, though woollen goods are manufactured. The borough is in the Banbury division of Oxfordshire. Area, 3.8 sq.mi.

CHIQUITAN, an independent linguistic stock of South American Indians, so called from the Chiquitos who are the best known of its tribes. The stock occupies a considerable area in eastern Bolivia, in the forested hilly country on the northern border of the Chaco. In recent times they have held the area between the headwaters of the Guapore on the north and the hills on the northern bank of the Otuquis river on the south, and between the San Miguel river in the west and the Paraguay in the east. It is probable that they formerly extended farther west to the foothills of the Andes and may have been forced eastward as a result of the displacements of peoples consequent on the invasion and settlement of the Chiriguanos in the early 16th century. The Chiquitos were a rather warlike and originally mainly nomadic hunting and fishing folk of simple culture. Their name, meaning "little ones" in Spanish, was given them on account of the very small doorways of their tiny thatched huts, through which one had to crawl on hands and knees. They seem to have had some palisaded strongholds and to have used poisoned arrows. Some of the tribes made good pottery and simple textiles. They had no canoes. Monogamy was the rule except for the chiefs, who were not hereditary but chosen for valour and ability. The youth before marriage lived apart in a special house. The shamans appear to have used snakes a good deal in connection with their religious ceremonies. The best known tribe of this stock to-day is the Lenguas.

See J. P. Fernandez, *Relacion historial de las missiones de los Indios que llaman Chiquitos, etc.* (Madrid, 1726).

CHIRICAHUA NATIONAL MONUMENT, a tract of 10,529.8 ac. (about 16 sq.mi.) in the Coronado national forest in Arizona, U.S.A., remarkable for its "pinnacle" formations. The

original tract of 4,480 ac. was set apart as a Government reservation in 1924 but was enlarged to the present area in 1938.

CHIROL, SIR VALENTINE (1852–1929), British journalist, was born on May 23, 1852, and educated in France and Germany. He graduated Bachelier-ès-lettres of the University of Paris. From 1872 to 1876 he was a clerk in the Foreign Office and afterwards travelled throughout the Near and Far East. He succeeded Sir Donald Mackenzie Wallace in 1899 as foreign editor of *The Times*. He retired from the service of *The Times* in 1912, and then became a member of the Royal Commission on Indian Public Services (1912–16). He wrote authoritative works on India, Egypt and the Far and Near East, and in 1927, he published a volume of reminiscences entitled *Fifty Years in a Changing World* to which a second volume, *With Pen and Brush in Eastern Lands*, was added in 1929. He was knighted in 1912 and died in London on Oct. 22, 1929.

CHIROMANCY, the art of telling character or fortune by studying the lines of the hands (*see* PALMISTRY).

CHIRON or **CHEIRON,** in Greek mythology, one of the Centaurs, the son of Cronus and Philyra, a sea nymph. He dwelt at the foot of Mount Pelion, and was famous for his wisdom and knowledge of the healing art. He offers a remarkable contrast to the other Centaurs in manners and character. Many of the most celebrated heroes of Greece were brought up and instructed by him (Apollodorus iii, 10. 13). Accidentally pierced by a poisoned arrow shot by Heracles, he renounced his immortality in favour of Prometheus, and was placed by Zeus among the stars as the constellation *Sagittarius*.

CHIROPODIST (Podiatrist). One who diagnoses and treats conditions affecting the feet. The first podiatrist was Dr. Lyon who, in 1785 in England, applied for a licence to limit practice to the foot alone. Chiropody practice in the United States was governed by law in all but two states in 1941. Competent podiatrists have the degree of doctor of surgical chiropody (D.S.C.) from recognized schools.

CHIROPRACTIC, "a system of therapeutics based upon the theory that disease is caused by interference with nerve function. Its theory is based upon the premise that all other systems and physiologic processes of the human body are controlled and coordinated by the nerve system. Its therapeutics attempts to restore normal function of the nerve system by manipulation and treatment of the structures of the human body, especially those of the spinal column." Daniel David Palmer began to formulate its theory in 1895, and established the Palmer School of Chiropractic at Davenport, Ia., in 1903. Later others were founded in different parts of the United States and, by 1941, the National Chiropractic association had extended accredited ratings to 12 colleges teaching a scientific course of four collegiate years. The practice of chiropractic has been accorded legislative recognition in 42 states, the District of Columbia, Alaska, Hawaii and several provinces of Canada. It is estimated that there are about 18,000 chiropractors practicing in the United States and Canada.

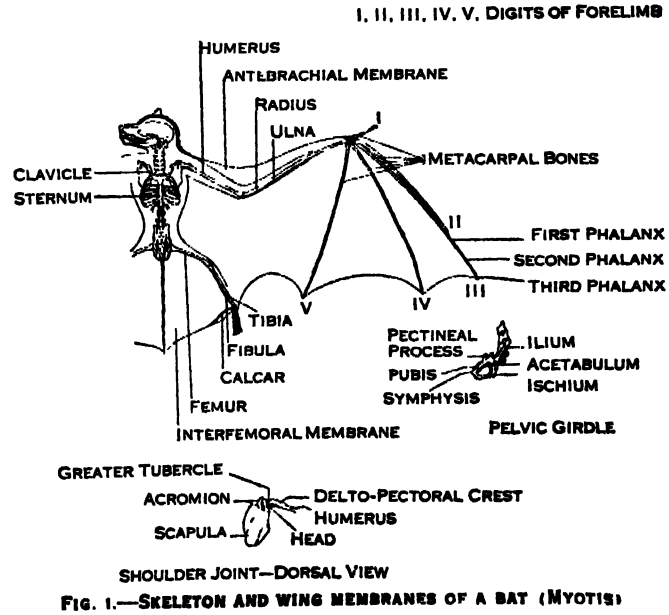
CHIROPTERA, the order of mammals containing the bats. They are the only members of this class which can truly fly and their forelimbs are modified to form wings, whence the name Chiroptera (from the Greek, meaning "hand-wings").

Bats not very different from those that still exist have been found in the early part of the Eocene period, indicating that the order is an ancient one. No animals are known that connect the bats closely with other groups of mammals, but the great resemblances between them and some of the Insectivora (*q.v.*) indicate these are probably the most closely related order. The existence of the so-called "flying lemur," *Cynocephalus*, suggests how the transformation from tree-living to flying took place. This animal possesses extensive folds of skin connecting its neck, wrists, ankles and tail, and even between the fingers and toes. These membranes enable it to glide long distances between trees and even to control its course somewhat during the glide. The ancestral bats progressed further in this direction. They developed extremely long forearm and fingers and extended the skin web between these. Their breast muscles increased in power until they were able to beat the forelimbs and wing membranes against the air and thus propel themselves through it. The side and tail membranes support bats in the air between wing beats, and the latter acts as a powerful brake when the end is brought forward under the body. The impervious nature of the wing membranes, their elasticity, and the manner in which they fold up on the fingers, somewhat as an umbrella does on its stays, tend to make the flight of bats both efficient and erratic.

Once this ability to fly was achieved, the bats underwent evolutionary diversification chiefly in minor details. Often the various stages in these modifications still persist in the various living species, and it is possible partly to reconstruct the changes. The upper armbone, or humerus, in the weaker flying bats has its usual simple ball-and-socket articulation with the shoulder blade, while the groups which fly best, the families Vespertilionidae and Molossidae, have developed a second joint between the greater tubercle of the humerus and the scapula. These swift-flying bats have a short upper arm as compared with the forearm, and the third finger is much longer than the others. The humerus has a small but well developed crest for the attachment of the deltoid and pectoral muscles; its shaft is rounded and it varies in shape from somewhat curved in the lower bats to almost straight in the higher groups. Of the two bones generally found in the forearm, the radius alone is well developed, the ulna being little more than a thread and often almost completely fused with the radius. A bone is developed in the tendon of the triceps muscle near the elbow, somewhat resembling the kneecap and with a similar function. The wristbones, six in number, are small. The metacarpal bones, except for that of the thumb, are greatly lengthened, forming the chief supports of the wing. The short thumb is separate from the rest of the wing; its claw is sharp and hooked in most bats, and it is used to grapple the surface in crawling; and some species occasionally swing from branches by the thumb. In certain bats the thumb is provided with a round adhesive disk by means of which they can rest upside down on a smooth surface, such as a banana leaf (fig. 18).

The second, or index finger, except in the fruit bats and the mouse-tailed bat, has lost its terminal joints, consisting only of the metacarpal and a poorly developed cartilage. This finger is generally closely associated with the middle, or third finger, and strengthens it. The third, fourth and fifth fingers have three joints or phalanges as a rule, but the last of these is usually cartilaginous. When bats rest, the phalanges are often bent, sometimes in zigzag fashion to fold the wing more completely.

The shoulder girdle is well developed, with a stout curved clavicle, or collarbone, and broad scapula, or shoulder blade. The coracoid process of the latter is large, usually curved outward but occasionally inward and dorsally. Its base articulates with the secondary articular process developed from the greater tubercle



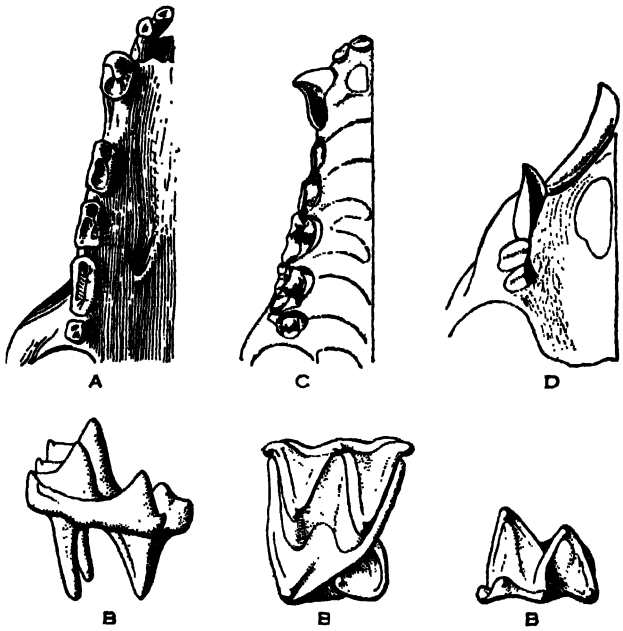


FIG. 1.—SKELETON AND WING MEMBRANES OF A BAT (MYOTIS)

of the humerus. The sternum, or breastbone, consists of three parts, the more or less T-shaped presternum or manubrium, the body of the sternum and the xiphisternum. The presternum is large, strongly keeled for the attachment of the flying muscles of the breast, while the lateral processes articulate with the clavicle and first rib. The keel continues down the body of the sternum, gradually becoming lower. The xiphisternum is short, often expanded posteriorly and partly cartilaginous.

The thorax is capacious, to accommodate the large heart and lungs, and the ribs are often flattened and close together. The first rib consists of two parts; it is usually thickened and much shorter than the others. The ventral segment frequently articulates with the clavicle. In the horseshoe and leaf-nosed bats (Rhinolophidae) the first or first two ribs are fused with both the sternum and their vertebrae to form a solid ring supporting the shoulder girdle. The pelvic girdle is weaker than the pectoral; its dorsal border is usually almost straight and almost on the same plane as the sacrum. The ilia are generally narrow but occasionally shelflike, while the pubis and ischium are generally narrow. A well developed pectineal process extends forward from the pubis and in the Hipposiderinae it unites with a process from the ilium to form a large foramen. The acetabulum or hip socket is often incomplete, dorsally or ventrally or both.

The hind limbs support the side membrane and that of the tail. The head of the femur is almost in the same axis as the shaft, so that the thigh projects almost at right angles to the body. The knee bends outward and backward rather than forward like that of terrestrial mammals. The foot is weak—the toes all about the same size and armed with sharp hooked claws by which the bat hangs, as a rule, when resting. The heel bone bears a long cartilaginous process, the calcar, rarely rudimentary or absent, which supports part of the posterior margin of the interfemoral membrane extending from the tail or hinder part of the body to the hind limbs.

The tail varies greatly in the different groups of bats; in primitive forms it is long and generally free from the membrane. Only one of the fruit bats has a long tail, as long as the hind limbs, the genus *Notopteris*, found in the southwestern Pacific. In other fruit bats the tail is either very short or absent. Most of the insectivorous bats have a well developed tail, but the mouse-tailed bat, *Rhinopoma*, has a long tail almost completely free from the interfemoral membrane. In the sheath-tailed bats (Emballonuridae) the tail is partly enclosed in the membrane but its distal end projects through the dorsal surface. In most other families the tail extends to the end of the large interfemoral membrane, as its median support.

FROM (A) MILLER IN "UNITED STATES NATIONAL MUSEUM BULLETIN"; (B) MILLER, "THE FAMILIES AND GENERA OF BATS" (SMITHSONIAN INSTITUTION); (C) H. ALLEN, "ON THE GLOSSOPHAGINAE" BY COURTESY OF THE AMERICAN PHILOSOPHICAL SOCIETY; (D) MILLER, "THE FAMILIES AND GENERA OF BATS" (U.S. NATIONAL MUSEUM)

FIG. 2.—DENTITION OF BATS

A. Upper dentition, *Pteropus*, typical fruit bat; B. Side and crown views of molars of typical insectivorous bat, showing W-pattern of main cusps. Lower molar on left; C. Modified insectivorous dentition of *Glossophaga*, a tropical American fruit-eating bat; D. Trenchant dentition of *Desmodus*, the vampire bat

The skull varies a great deal in the different groups and it is used to characterize these. There is a tendency for the facial portion to become shortened in the more progressive forms, but all extremes are found from elongate snout to a short massive one.

The teeth comprise incisors $\left(\frac{2-1}{3-0}\right)$ canines $\left(\frac{1}{1}\right)$, premolars $\left(\frac{3-1}{3-2}\right)$ and molars $\left(\frac{3-1}{3-1}\right)$, totalling from 38 to 20. The cheek teeth of fruit bats have poorly marked cusps, their squarish crowns bearing a large outer and a smaller inner cusp, which become gradually reduced toward the posterior end of the series. The pattern of these teeth of fruit bats has probably been simplified from the insectivorous pattern. In the molars of insectivorous bats the cusps on their surfaces show a W-pattern in both upper and lower teeth, the upper ones broader, with an additional shelf and "talon" cusp. They thus resemble closely the teeth of certain insectivorous mammals of similar food habits, the hedgehogs, the jumping shrews, moles and shrews. The cusps on the cheek teeth the vampires are greatly simplified, the teeth being specialized into blades for cutting. The milk teeth are quite unlike those of the permanent series, being slender and hooklike, sometimes with forked or trifid tips, and are soon shed.

FROM MILLER, "THE FAMILIES AND GENERA OF BATS" (SMITHSONIAN INSTITUTION)

FIG. 3. DECIDUOUS DENTITION OF PROMOPS, AN INSECTIVOROUS BAT

The brain is not highly developed; the cerebral hemispheres are smooth or only slightly furrowed and do not extend back over the cerebellum. However, bats have a delicate sense of touch; tactile hairs exist on the region around the mouth, on the flying membranes and ears. Each hair is provided with a nerve ending that surrounds its base. The expanded ears and noseleaves may also serve as organs of touch, although special nerves are not known. The sense of scent appears to be only moderately well developed, but hearing is keen, especially for notes higher than those heard by the human ear. This is of great importance in flight, for the bat emits high-pitched cries continuously and solid objects reflect these sounds, warning the bat of obstacles. The eyes of bats, although small, are far from blind; bats see fairly well but depend more on their hearing to find food and to avoid collisions. In no animal are the ears so developed or so variable in form; in many insectivorous species they are longer than the head, while in the Eurasian long-eared bat their length nearly equals that of the body. The "earlet," or tragus, is generally large in the insectivorous bats but is never present in the Megachiroptera nor in the insectivorous Rhinolophidae.

The stomach is of two types, corresponding to the two suborders, Megachiroptera and Microchiroptera. In the latter group the stomach is simple and almost spherical. In the fruit bats the narrow oesophagus gradually enlarges just before reaching the stomach. The stomach is enlarged transversely, with a large cardiac sac and a tapering pyloric portion which gradually passes into the intestine. The vampire bat, one of the Microchiroptera, feeds on blood; its stomach has a long tubular cardiac portion, folded on itself, but the pyloris is hardly distinguishable from the small intestine. The intestine is short in insectivorous bats, in some of which it is shorter than in any other mammal, but may be four times the body length in the fruit-eating types.

As a rule bats produce only a single young at a birth, but among the insectivorous types two or even four young may occur. These are born with closed eyes and nearly naked; they are able to climb up the mother's skin to the nipples, where they attach by the delicate hooklike deciduous teeth. The young bats remain attached to the mother for some time and she may fly about with them while hunting her prey. In many species of the northern hemisphere the mating period is in the fall; the sperm remain

inactive during the winter. Early in spring, when the bats become active again, ovulation occurs in the females and the egg cells are fertilized. The penis is pendulous; often there is a bone in its distal part. The uterus of females is primitively double; in some species the uterus consists of a rounded body with long horns, while in others the horns are greatly reduced. A simple uterus is formed in some of the Phyllostomidae. The placenta is discoidal and deciduate, as in the Primates. Bats are divisible into two suborders: the Megachiroptera and the Microchiroptera.

MEGACHIROPTERA

The first of these suborders comprises the fruit bats, generally of large size. The crowns of their cheek teeth show only poorly marked cusps which never form a W-pattern. The bony palate extends behind the last molar, narrowing slowly backward. The greater tubercle of the humerus is poorly developed and does not articulate with the scapula. The second finger is partly independent from the third and retains three phalanges, the terminal one generally with a claw. The margins of the ear unite to form a ring at the base. The tail, often absent, is free from the interfemoral membrane. This group is limited to the tropical and subtropical parts of the eastern hemisphere. All the members of this suborder are included in the single family Pteropodidae, which may be divided into four subfamilies.

REDRAWN FROM A PHOTOGRAPH, NEW YORK ZOOLOGICAL SOCIETY

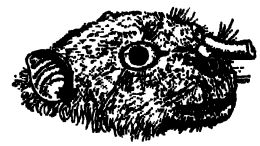

FIG. 4.—FLYING FOX (PTEROPUS)

The subfamily Pteropodinae contains a large majority of the frugivorous genera. It is characterized by having a normal tongue, blunt-crowned cheek teeth, canines which are vertically directed and the lower pair separated from each other by the incisors, and premaxillary bones which are separated or only barely united.

The Pteropodinae may be divided into three tribes. The pteropodine tribe is characterized by having the occipital part of the skull deflected (the alveolar line projected backward passes above the occipital condyle); the muzzle is long, about equal to the postorbital part of the head. The first representatives of this group, the flying foxes (*Pteropus*) are found from the Comoro Islands and Madagascar to southern Japan, Samoa and Tasmania; they have foxlike faces, two lower incisors on each side and no tail; the occiput of the skull is elongated and tubular. Most species have a brilliantly coloured mantle, although this varies from light yellowish buff or even whitish to dark brown or blackish. *Styloctenium wallacei* of Celebes resembles *Pteropus*, but the lower incisors are 1–1; its general colour is pale grayish to warm cinnamon above, with a white shoulder patch, light cinnamon under parts and a whitish or creamy mantle. The dog-faced bats (*Rousettus*), found throughout Africa and east to the Solomon Islands, have a short tail, the occiput of the skull is not tubular and the muzzle is shorter and coarser than that of *Pteropus*; in colour they are generally dark dull brown. The yellow fruit bat (*Eidolon*) occurs in Africa, from Southern Arabia and the Sudan to Namaqualand; it differs from other fruit bats in having a bony external ear tube. *Boneia bidens* of Celebes combines characters of *Pteropus* and *Rousettus*, having a tail, tubular occiput of the skull, but its incisors are $\frac{1-1}{2-2}$. The spinal-winged bat (*Dobsonia*) is found from Celebes and Bali to the Solomon Islands and Queensland; its wings are attached to the mid-line of the back rather than to the sides of the body and the index finger of the wing has no claw; in colour the various species are dark brown, usually with an olive cast, lighter on the underparts; the muzzle is heavy, shorter than in *Pteropus*, and the cheek teeth are heavy and crowded.

The epomorphorine tribe contains only African species. It is characterized by the brain case being flattened posteriorly (the alveolar line produced posteriorly passes below the occipital condyle or through its lower part); the muzzle is generally long but may be quite short; the upper cheek teeth are three or four on each side; there are whitish hair tufts before, and usually behind, the ear. *Plerotes*, known only from Angola, has narrow, weak cheek teeth, four in number above; the occiput of the skull is deflected more than typical of this group, and in coloration it is a dull fawn. The epaulet bats (*Epomophorus*) vary from small short-faced species to larger, long-faced types. They are fawn-coloured; the males have erectile whitish or yellowish shoulder pouches, from which the species received its common name. The hammer-headed bat (*Hypsignathus*) of the Congo and West Africa has an enormous muzzle, especially the adult males, swollen, pendulous lips and extensive cheek pouches; it is grayish-brown in colour. The males emit loud cries during the night, frequenting mangroves and palms along the river. *Casinycteris* of the Cameroons is a short-faced, broad-headed species, differing from all its relatives by the reduced palate, which ends shortly behind the last molar; it is fawn-coloured, with a white blaze on the face.

The short-faced fruit bats of India and the Malay region, east to the Molucca Islands, Timor and the Philippines, form the third, or cynopterine, tribe. They have the occipital region on the same plane as the upper alveolar line. *Cynopterus* occurs throughout the range of the group, including about a dozen species; a small tail is present; the lower incisors are 2–2, while the cheek teeth are $\frac{4-4}{5-5}$. *Sphaerias* of Burma is like *Cynopterus* but the calcar or spur, which usually supports the interfemoral membrane, is absent, as is also the tail. *Balionycteris* has spotted wings, the tail is absent and the cheek teeth are $\frac{5-5}{5-5}$; it occurs in Borneo. *Ptenochirus* has lower incisors 1–1, cheek teeth $\frac{4-4}{5-5}$, a short tail or none. The typical species occurs in the Philippines; related forms are found on the Malay peninsula, Borneo and Sumatra. The flying foxes and their relatives feed on many fruits, such as figs, guavas, bananas, dates and others. Flowers and their buds are frequently taken and some species have been known to gnaw bark of young trees. In the tropics some fruit or flowers are almost always available.

FROM DOBSON, "PROCEEDINGS OF THE ZOOLOGICAL SOCIETY"

FIG. 5.—TUBE-NOSED FRUIT BAT, NYCTIMENE

The subfamily Nyctimeninae includes two genera of tube-nosed fruit bats. They are short-faced, with their nostrils drawn out into tubes; their lower canines are in contact, the lower incisors being absent; and in the skull the premaxillary bones are strongly united. The tail is about as long as the lower leg. The wings and ears are usually yellowish spotted. *Paranyctimene* has sharp-cusped cheek teeth, while those teeth in *Nyctimene* are almost as blunt as in most fruit bats. Both of these may feed on insects rather extensively, in addition to fruit.

The subfamily Harpyionycterinae contains only a single genus, *Harpyionycteris*. Like *Nyctimene*, it has the premaxillary bones broadly fused; the canines slant forward, crossing when the jaws are closed, the lower incisors are usually absent. The cheek teeth each show five or six sharp cusps. The skull is like that of the pteropodine fruit bats, with a long face. The harpy fruit bat is chocolate brown in colour, small in size and the tail is absent. It is known only from the Philippine Islands and Celebes.

The subfamily Macroglossinae includes a number of small, long-faced fruit bats, generally less than 5 in. in head and body length. The long, narrow tongue is free for its anterior two-thirds, protrusile and armed with recurved filiform papillae. Their cheek teeth are narrow, incisors greatly reduced in size, the mandibular symphysis is long and the brain case strongly deflected. They feed on soft fruits, the nectar and pollen of flowers, probably also on insects found in them. Bats of this group are found from India to the Fiji Islands and Australia, while one

form occurs in West Africa. Two sections of Macroglossinae have been distinguished. The macroglossine tribe, with a narrow ascending process of the premaxillary bone, contains three genera. *Eonycteris*, characterized by relatively large cheek teeth ($\frac{5}{6}$ or $\frac{5}{5}$ on either side), a short tail and the index finger without a claw, is found from Burma to the Philippines and Celebes. *Megaloglossus*, characterized by bilobed lower incisors, no tail, and males with pale neck-ruffs, has an African distribution from Liberia to the Belgian Congo. *Macroglossus* occurs from India to the Solomon Islands and northern Australia; cranially the brain case is strongly deflected, the infraorbital canal generally long; the index finger is clawed and there is no tail. The notopterine tribe, the skull with the ascending process of the premaxilla broad, contains three genera. *Melonycteris* of New Guinea and the Bismarck archipelago is golden brown in colour above, with dark under parts and small white epaulettes in males; the index finger bears a claw; the tail is absent; the skull is almost semicircular in dorsal outline and the infraorbital canal is long. *Nesonycteris* of the Solomon Islands has under parts paler and duller than the russet-brown back; the index finger is clawless; there is one minute lower incisor on either side instead of two. The long-tailed flower bat (*Notopteris*), of New Caledonia, the Carolines, the New Hebrides and Fiji Islands, is the only fruit bat with a tail reaching to the heel; the wings take origin from the middle of the back; cranially it resembles *Melonycteris* and *Nesonycteris* but has only one upper and one lower incisor on each side.

MICROCHIROPTERA

The second and larger suborder contains the insectivorous bats, most of which are of relatively small size. Their teeth are usually adapted for cutting up hard-bodied insects, the sharp cusps being arranged in W-pattern (fig. 2 B). The rim of the ear does not form a ring, as in the fruit bats. The angular process of the mandible is long and slender. The greater and lesser tubercles of the humerus are well developed and the former usually articulates with the scapula. The index finger never bears a claw and, except in a few species, lacks bony phalanges. As the suborder contains 600 or more different forms, it will be possible only to outline the various families and subfamilies, with special mention of some of the more important types.

The Microchiroptera may be divided into four superfamily groups, including 15 recent families.

(1) Superfamily Emballonuroidea is characterized by the premaxillaries being generally free, the ascending process the most important part. The greater tubercle of the humerus is small; only in the Noctilionidae does it articulate to a small degree with the scapula. The third digit bears two well developed phalanges. The teeth are normal.

Family Rhinopomidae includes only the genus *Rhinopoma*, the mouse-tailed bat, found from Egypt to Burma and Sumatra. The interfemoral membrane is small, while the tail is slender and extremely long. The muzzle is broad, with a poorly developed nose-leaf; the ears are long and the index finger has two bony joints. The skull has a short rostrum, the dorsal surface of which exhibits a depression; there are no postorbital processes.

F NATURAL
TIN OF THE
HISTORY"

FIG. 6.—TAIL OF THE MOUSE-TAILED BAT (RHINOPOMA)

Family Emballonuridae, the sheath-tailed bats. The tail projects through the interfemoral membrane on the upper side. The basal phalanx of the third finger folds back on the upper side of the metacarpal bone when the wing is folded. The face is pointed, the nostrils project in front of the lips and there is no nose-leaf. The skull shows postorbital processes and the premaxillary bones are independent, without palatal processes. In subfamily Emballonurinae the postorbital processes are long and curved, the clavicle or collarbone is normal (its greatest breadth less than a quarter of its length). Bats of this group in the old world: *Emballonura*, with incisors $\frac{2-2}{3-3}$ and of small size, is found in Madagascar, the Malay region and eastward to Samoa; *Taphozous*, the tomb bats, has incisors $\frac{1-1}{2-2}$, a deep depression in the forehead of the skull, often a glandular throat-sac—bats of this genus are medium-sized or large and occur from Africa and southern Asia to the Philippines and Australia; *Coleura*, of eastern Africa and the Seychelle Islands, resembles *Emballonura* but has one upper incisor on each side. The sheath-tailed bats of the new world tropics (*Saccopteryx* and allies) have antebrachial pouches on the wings, the upper incisors are 1–1 or absent, and they are small or medium-sized species. *Rhynchiscus* of the same region lacks the wing pouch and has a long muzzle, although the rostrum of the skull is short. Subfamily Diclidurinae is characterized by the short and straight postorbital processes of the skull and a greatly expanded collar-bone (its breadth more than one-third of the length). The interfemoral membrane is glandular. *Diclidurus*, the white bat, is widely distributed in tropical America. *Drepanonycteris* has whitish head, shoulders and underparts, but the back becomes brownish.

FROM ALLEN, LANG AND CHAPIN IN "BULLETIN OF THE AMERICAN MUSEUM OF NATURAL HISTORY"

FIG 7.—A. HEAD OF SHEATH-TAILED BAT (TAPHOZOUS); B. TAIL AND INTERFEMORAL MEMBRANE

Family Noctilionidae, the hare-lipped bats of tropical America and the West Indies, have a curiously folded upper lip, the middle forming an inverted V. The second finger has a rudimentary phalanx and the terminal phalanges of the third and fourth fingers fold under when at rest. The hind feet and claws are large and the ears long and pointed. There are cheek pouches but no nose-leaf. The incisors are $\frac{2-2}{1-1}$; both nasal and palatal processes of the premaxillaries are developed and these bones unite with the maxillaries in adults. The shoulder joint is strengthened by a small articulation of the greater tubercle of the humerus with the scapula. The hip-bones are solidly attached to the spinal column, the ischia fused together and with the under side of the sacrum, and the symphysis pubis is absent in females. These large or medium-sized bats feed chiefly on fish, which they catch with their long feet. Two genera, *Noctilio* and *Dirias*, are distinguished, the latter by minor dental characters and shorter legs and feet.

FIG. 8.—HARE-LIPPED BAT (NOCTILIO)

FIG. 9.—SLIT-FACED BAT (NYCTERIS)

(2) Superfamily Rhinolophoidea contains bats characterized by degenerate premaxillary bones, without nasal processes, and often partly or wholly cartilaginous. The nostrils open in a complicated nose-leaf or margined by cutaneous outgrowths forming a deep longitudinal groove. The ears are large and the third finger bears only two phalanges.

Family Nycteridae, the slit-faced bats, are so called from a deep slit down the front of the face, into which the nostrils open. The edges of this are swollen but do not form a nose-leaf. The

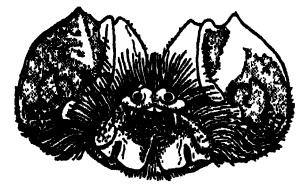
tail is long, included in the interfemoral membrane to the tip. The ear is large, with a simple tragus. The skull has poorly developed postorbital processes on the sides of an extensive frontal basin; the premaxillaries are represented only by their palatal portions. The humerus exhibits a poorly developed greater tubercle which does not articulate with the scapula. Only the single genus *Nycteris* is extant, found throughout Africa except for the northwest, and from Borneo and Java to Celebes and Timor.

TIN OF TH AMERICAN MUSEUM OF NATURAL HISTORY"

FIG 10.—FALSE VAMPIRE (LAVIA FRONS)

Family Megadermidae, the false vampires, are distributed from India and southern China to the Philippine Islands and Java, and in Australia and tropical Africa. The muzzle bears a nose-leaf; the tragus of the ear is large and bifid and the tail is short. The premaxillaries are almost completely cartilaginous and there are no upper incisors. *Megaderma* (including *Lyroderma* of many authors) ranges from southern Asia to Java and the Philippines; it is distinguished by having $\frac{5-5}{5-5}$ cheek teeth and only slightly concave frontal region. *Macroderma*, the Australian false vampire, is one of the largest of the insectivorous bats, the head and body length 4.92–5.11 in. It is pale grayish green, almost whitish in colour and has 4–4 upper cheek teeth and conspicuously concave frontal part of the skull. *Lavia* (including *Cardioderma* of some authors) of the savanna country of Africa, agrees with *Macroderma* in dental formula and cranially. In colour these bats are bright greenish gray.

FIG. 11.—HORSESHOE BAT (RHINOLOPHUS)



Family Rhinolophidae, the horseshoe and leaf-nosed bats, inhabits the tropical and temperate parts of the old world. The ears are large and lack a tragus and a complicated nose-leaf is developed. The tail is generally shorter than the hind legs. The rostrum of the skull is short, the nasal cavities inflated, and the premaxillaries are partly cartilaginous, the only ossified parts being a palatal strap bearing the small incisors. The greater tubercle of the humerus is large, articulating with the shoulder blade, and the first ribs, last cervical and first thoracic vertebrae tend to fuse with each other and the presternum to form a broad bony ring. The pelvic girdle is weak, the dorsal and ventral margins of the hipbone are almost parallel, the obturator foramen small. Two subfamilies may be recognized: the Rhinolophinae, with three joints in the second to fifth toes, the nose-leaf pointed above and broad below; the Hipposiderinae, with squarish nose-leaf, the toes with only two phalanges, the basal joint and the one bearing a claw. Subfamily Rhinolophinae, the horseshoe bats, contains only two genera. *Rhinolophus* is found throughout the tropical and temperate regions of the old world, from England and Japan to South Africa and Australia. Almost 100 species are recognized, ranging from small to medium in size (up to about 3.34 in. head and body length). *Chilophyla*, found only in the Philippines, has a broad, poorly differentiated horseshoe, the ears large and rounded. The thumb has a long metacarpal included in the antebrachial membrane, which forms a pouch. This rare

FROM ALLEN, LANG AND CHAPIN, "BULLETIN OF THE AMERICAN MUSEUM OF NATURAL HISTORY"

FIG. 12.—LEAF-NOSED BAT (HIPPOSIDEROS CYCLOPS)

bat is dull fawn colour, with long soft hair. Subfamily Hipposiderinae, the leaf-nosed bats, restricted to the tropics or warmer regions, are found throughout Africa and southern Asia, east to Australia and the Solomons. In addition to the characters given above, the thoracic ring is more extensive than in the Rhinolophinae, the hipbone contains a secondary pre-acetabular foramen and the lumbar vertebrae tend to fuse. The typical genus, *Hipposideros*, has a range coextensive with that of the subfamily. Some species are large, *H. gigas* being as much as 4.92 in., while others vary from 1.57 in. to 3.46 in. head and body length. Many species are represented by bright red varieties. One grizzled brown species of Africa, *H. cyclops*, has a curious eversible pouch on the forehead, containing stiff whitish hairs. Other genera differ in precise dental formula and minor cranial characters. *Anthops* of the Solomon Islands has an extremely short tail and a rosette-like nose-leaf covering the face; at the top of this there are three hemispherical bodies, the rounded surfaces directed forward.

FROM DOBSON, "CATALOGUE OF THE CHIROPTERA" (BRITISH MUSEUM)

FIG. 13.—CHIN-LEAF BAT, MORMOOPS BLAINVILLII

(3) Superfamily Phyllostomatoidea is characterized by complete premaxillary bones in the skull, fused with each other and the maxillaries, and there is no postorbital process. The ears are moderately large, with a tragus. The third finger has three bony joints beyond the metacarpal, while the index finger has one phalanx. Many species have a nose-leaf. The shoulder joint includes both the head of the humerus and the greater tubercle (except in the Chilonycterinae).

FIG. 14.—JAVELIN BAT (PHYLLOSTOMUS)

Family Phyllostomatidae have well developed molar teeth, adapted for crushing insects or fruit. It is restricted to tropical and subtropical America. Subfamily Chilonycterinae contains three genera, differing from their relatives in having a primitive shoulder joint in which the humerus takes no part. The muzzle does not bear a nose-leaf but the lower lip is decorated with platelike outgrowths of skin. The tail membrane is large, supported in part by a long calcar or "spur." Two genera are noteworthy: *Pteronotus*, with wings attached along the mid-dorsal line, and *Mormoops*, with extremely shortened head, highly elevated brain case and extraordinary development of the cutaneous outgrowths on the chin (fig. 13). Subfamily Phyllostomatinae contains bats with a nose-leaf, usually shaped like a spearhead, on the muzzle. The greater tubercle of the humerus forms a secondary shoulder joint as it does in the following groups of this family. The molars have cusps arranged in the normal W-pattern. The best known genera are: *Phyllostomus*, the spear-nosed bat, represented by several species, 2.95 in. to 4.33 in. in head-body length and heavily built, with a well developed nose-leaf (fig. 14), short tail and incisors $\frac{2-2}{2-2}$; *Vampyrus*, the largest American bat, has a wing spread of about 27.55 in. and a head-body length of about 5.51 in., and *Macrotus* with large oval ears, head and body about 3.93 in. in length, is found as far north as California. The first two feed on other bats, small mammals and birds, in addition to fruit and insects, and are confined to tropical America and the West Indies. Subfamily Glossophaginae includes the long-nosed flower bats, adapted for feeding on nectar and pollen by their long brush-tipped tongue. In the skull, the zygomatic arch is slender or incomplete. The cheek teeth are long and narrow but show the W-pattern indistinctly, and the lower incisors are rudimentary. The nose-leaf is well developed though simple, and the ears small and separate. Subfamily Carolliinae is characterized cranially by incomplete zygomatic arch and cheek teeth simplified from the normal W-pattern to form cutting blades, the third molar patternless or with two low cusps. These bats feed on fruit, especially bananas, and are often very common. Subfamily Sturnirinae contains a single tailless, fruit-eating species, *Sturnira lilium*, with broad cheek teeth, the crowns of which have a longitudinal groove or valley laterally margined by two cusps. The muzzle is broad, with a normal nose-leaf. The males of this species have tufts of deep red stiff hair on the shoulders. Subfamily Stenoderminae includes a number of genera, short-faced and with a high brain case for the most part, the nose-leaf usually present, although sometimes rudimentary or absent; the tail is generally missing. The molar teeth are broad and short, the lateral cusps well developed, forming a cutting edge, a smaller medial cusp separated from these by a wide concavity, the enamel of which is often wrinkled. One of the best known genera is *Artibeus*, one form of which rarely reaches southern Florida. These bats are often large (up to 4.13 in. head and body length), marked by white lines on the head. *Uroderma* has similar head markings but in addition has a

FROM DOBSON, "CATALOGUE OF THE CHIROPTERA" (BRITISH MUSEUM)

FIG. 15.—LONG-TONGUED FLOWER BAT (CHOERONYCTERIS)

white stripe extending from the shoulders to the hind quarters. *Centurio*, the centurion bat, lacks a nose-leaf but the skin of the entire face is folded in grotesque fashion. Subfamily Phyllonycterinae resembles the Glossophaginae externally, with long rostrum, extensile tongue, armed with bristle-like papillae at the tip. The zygomatic arch is likewise incomplete. The upper molars, however, are triangular in crown view, without distinct cusps, most of the crown surface occupied by a groove. Such teeth could be best derived from the stenodermine or sturnirine pattern. The habits of this group are undoubtedly like those of the Glossophaginae. They are confined to the Bahama Islands and Greater Antilles.

BY COURTESY OF ANTHONY, "NATURAL HISTORY"

FIG. 16.—VAMPIRE BAT (DESMODUS)

Family Desmodontidae, the vampire bats, is restricted to the warmer regions of America north to southern Mexico. They agree with the Phyllostomatidae in most characters of the wing and limb girdles. The skin around the nostrils is folded, forming a poorly developed nose-leaf. The fibula is large, reaching the head of the tibia, and the teeth are specialized for cutting, being narrow blades without any crushing surface. The cheek teeth are reduced and of little function. The stomach is reduced to a long slender tube, folded upon itself. Three genera are recognized, of which *Desmodus* is the best known, *Diaemus* and *Diphylla* being extremely rare. These bats feed on blood, apparently being unable to take any other food. (*See* VAMPIRE.)

(4) Superfamily Vespertilionoidea includes the typical bats, the free-tailed bats and several small families. In this group the premaxillaries are complete, although often separated by a gap, and are fused with the surrounding bones. The greater tubercle of the humerus articulates in a secondary joint with the scapula. The ears are provided with a tragus, although it may be small. Except for the Australian long-cared bat, *Nyctophilus*, the muzzle does not bear a nose-leaf. The molars show a well-marked W-pattern.

FROM DOBSON, "CATALOGUE OF THE CHIROPTERA," COURTESY OF THE BRITISH MUSEUM

FIG. 17.—LONG-LEGGED BAT (CHILONATALUS)

Family Natalidae, the long-legged bats, includes several delicately built genera from the American tropics and subtropics. In all but one genus (*Nyctiellus*) the ears are funnel-shaped. The muzzle is long and relatively broad. The lumbar vertebrae are fused together, except for the last two, the presternum large and strong, with a well developed backward slanting keel. The third finger has two phalanges. The brain case is domelike, rising high above the rostrum.

A B C

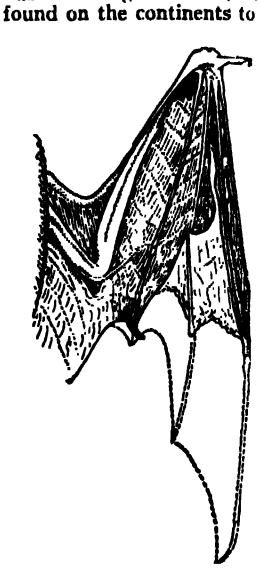
COUNCIL

FIG. 18.—SUCTIONAL DISKS IN THYROPTERA
(A) Side, (B) concave surface of thumb disk, (C) foot, with disk and calcar

Family Furipteridae is restricted to the tropical parts of South America. The bats of this group resemble the preceding but the thumb is vestigial, included in the wing membrane to the base of the functionless claw. The premaxillary bones have a poorly developed palatal branch and are widely separated from each other. The two genera recognized, *Furipterus* and *Amorphochilus*, both have high-crowned skulls.

Family Thyropteridae, containing only a single genus, is restricted to tropical America, north as far as Honduras. The thumb and the sole of the foot (fig. 18) bear sucking-disks and the former has also a well developed claw. The lumbar vertebrae are independent. The dental formula on either side agrees with the Natalidae (incisors $\frac{2}{3}$, canines $\frac{1}{1}$, premolars $\frac{3}{3}$, molars $\frac{3}{3}=38$) and contains one more upper premolar than in the Furipteridae.

Family Myzapodidae contains only the sucker-footed bat of Madagascar related to the Natalidae and Thyropteridae. The index finger has a cartilaginous rod in addition to the metacarpal, probably representing the phalanges, while the third finger exhibits three bony phalanges. The thumb and sole of the foot bear adhesive disks; the toes have only two phalanges. The tragus is fused with the ear conch on the anterior side, and the ear opening is partly closed by a mushroomlike process. Cranially the premaxillary bones are complete, surrounding the incisive foramen. The teeth number 38, including incisors $\frac{2}{3}$, canines $\frac{1}{1}$, premolars $\frac{3}{3}$ and molars $\frac{3}{3}$ on each side.



ITY PRESS)

FIG. 19.—MOUSE-EARED BAT (MYOTIS LUCIFUGUS) IN FLIGHT

Family Vespertilionidae contains the typical insectivorous bats and is almost world-wide in distribution. The muzzle and lips are simple; except for one subfamily (Nyctophilinae) there is no nose-leaf and the ears are separate. The long tail extends to the edge of the broad interfemoral membrane and rarely projects more than one vertebral joint beyond it. The two incisors on each side of the upper jaw are separated by a considerable gap. The secondary shoulder joint is well developed, the greater tubercle projecting well above the head and articulating with a large facet on the shoulder blade. The ulna is usually fused with the proximal end of the radius, the shaft of the ulna reduced to a poorly ossified thread. The family is divided into six subfamily groups.

Subfamily Vespertilioninae contains about 20 genera and is as widely distributed as the family, being found on the continents to the limits of tree growth and on all but a few mid-oceanic islands. The best known genera are: the mouse-eared bats (*Myotis*), with about 75 species, found on all the continents, characterized by $\frac{6-6}{6-6}$ cheek teeth; the pipistrelles (*Pipistrellus*), with nearly as wide a range and almost as many species, have cheek teeth $\frac{5-5}{5-5}$, incisors $\frac{2-2}{3-3}$, and are usually smaller, only rarely more than 2.75 in. head and body length; the serotines and brown bats (*Eptesicus*), also widely distributed and represented by numerous species, have $\frac{4-4}{5-5}$ cheek teeth; the long-cared bats (*Plecotus*) are widely distributed in the northern hemisphere and have ears almost as long as their bodies. Numerous other bats belong here.

TIN OF T HISTORY"

FIG. 20.—WING OF BENT-WINGE BAT (MINIOPTERUS)

Subfamily Miniopterinae. The bent-winged or long-fingered bats, represented by a single genus (*Miniopterus*), occur in southern Europe, Africa, Asia and the Pacific islands east to the Loyalties. The first phalanx of the third finger is short, only about a third as long as the second phalanx; this second phalanx and the equivalent joint of the fourth finger are folded back on the under side of the metacarpa when the bat rests. The crown of the skull is domelike and high an the cheek teeth are $\frac{5-5}{6-6}$. Long-fingered bats are usually small, wit large wings.

TIN OF THE AMERICAN MUSEUM OF NATURAL HISTORY"

FIG. 21.—FREE-TAILED BAT (TADARIDA)

Subfamily Murininae. The tub nosed insectivorous bats are four in southern Asia and the Malaysia islands, east to Java and north Japan. The nostrils form elonga tubes much like those of the fru bat *Nyctimene*. The first upp premolar is not very different fro the second in pattern, althou smaller. Two genera are includ here, one (*Harpiocephalus*) chara terized by the V-pattern of the fi two upper molars, unlike the no normal W-pattern of *Murina*.

Subfamily Kerivoulinae. T trumpet-eared bats are confined the tropical and subtropical regions of the old world, east as far the Solomon Islands. The well developed ears are funnel-shap with long slender tragi. The sternum differs from that of other b by its shortness, less than twice as long as the breadth of the p sternum, and only four or five ribs articulate with it. The skull

high-crowned and the teeth number 38 (incisors $\frac{2}{3}$, canines $\frac{1}{1}$, premolars $\frac{3}{3}$, molars $\frac{3}{3}$). Three genera are known: one (*Anamygdon*) is confined to the Solomons; *Phoniscus*, with four-lobed lower incisors, occurs from the Malay peninsula and Sumatra to New Guinea; *Arivoula*, with three-cusped lower incisors, is widely distributed in the warmer parts of the old world.

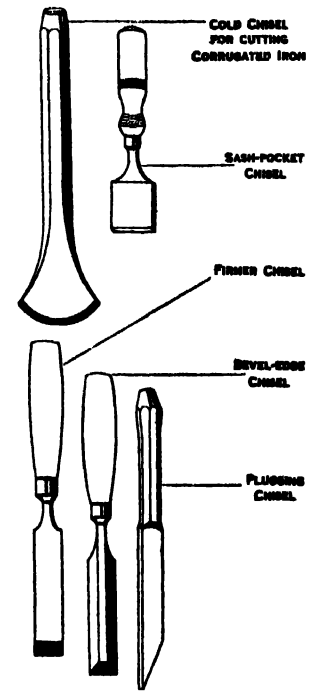
Subfamily Nyctophilinae contains two genera confined to Australia and New Guinea, and one found in North America. The muzzle is truncate, the nostrils opening beneath a horseshoelike ridge or small nose-leaf. *Antrozous*, of western North America from Texas to the Pacific and from Oregon to central Mexico, has long ears and incisors $\frac{1-1}{2-2}$. *Nyctophilus*, the long-eared bat of Australia and New Guinea, has incisors $\frac{1-1}{3-3}$, and there is a small nose-leaf.

Subfamily Tomopeatinae includes only a single genus, *Tomopeas*, found in Peru. The ear resembles that of the Molossidae, without anterior basal lobe and the tragus short and blunt. The upper lip is widely spreading but not heavily wrinkled. The seventh cervical vertebra is fused with the first dorsal, as in the free-tailed bats. Externally *Tomopeas* resembles a small pipistrelle.

Family Mystacinidae includes only the New Zealand bat, one of two species found in New Zealand. The feet are short and broad, the claws bearing accessory talons at the base. The fibula is complete and relatively large, forming with the tibia a stout lower leg. The tail projects from near the middle of the upper surface of the interfemoral membrane. The third finger bears three bony phalanges, the first of which is bent back on the upper surface of the metacarpal when at rest. In the vespertilionine skull, the premaxillary bones are complete, isolating two small incisive foramina.

Family Molossidae contains the mastiff, or free-tailed bats. The group is found in the warmer parts of both hemispheres, north to southern Europe and Asia, east to New Guinea, Australia and Norfolk Island; in America, north to the central United States and throughout the West Indies. In these bats the double articulation of the shoulder joint is perfected. The wing is long and narrow, the fifth finger much shortened, and the membranes thick and leathery. The tail projects beyond the interfemoral membrane, which can be contracted or expanded along the tail, somewhat like an awning. The ears are frequently joined across the forehead, the tragus much reduced. The muzzle is obliquely truncate, the upper lip broad and wrinkled, usually sprinkled with short spoon-tipped hairs. The lower leg is stout and contains a complete fibula, relatively strong and bowed out. Cranially, the premaxillaries are either united medially, enclosing the small incisive foramina, or are separated by a narrow space. About 12 genera are recognized. *Cheiromeles*, containing a single species, *C. torquatus*, from the Malay peninsula and the islands, east to Java and north to Palawan, is one of the strangest appearing bats, with long pig-like snout, widely separated ears, almost naked, wrinkled skin and large opposable first toe. A large pouch under each wing may serve to carry the young. This bat is one of the largest of the insectivorous group (head and body 5 31 in., tail 1.77 in. and forearm about 3.34 in. *Tadarida* has a range coextensive with that of the family, being found in the tropics and warm parts of the old and new world. The ears are large and rounded, arising from the middle of the head or joined by a narrow ridge. The fur covering the body is extremely fine and oily and males of many species have erectile crests on the forehead. Most species have the premaxillaries incomplete, the upper incisors separated by a space, but all gradations exist between this condition and complete premaxillae, with the upper incisors almost in contact. The upper cheek-teeth are 5-5 in number, the last molar often narrow, with a simplified V-pattern. Several species found in Malaysia, central Africa and the West Indies have elongate skulls and very large ears. *Myopterus*, an African genus, has transparent flesh-coloured wings and creamy white under parts. The ears in this bat are pointed and more erect than is usually the case in the Molossidae. The upper lip is not wrinkled; in front it is covered with relatively large "spoon-hairs." The upper incisor teeth are strongly in contact with each other and with the canine; the cheek-teeth are $\frac{4}{5}$ on each side. The skull is long and low, with sagittal crest poorly marked. *Molossops*, represented by several South American species, has procumbent upper incisors and broad low skull with large antorbital ridge but weak sagittal crest. The premaxillaries are complete, enclosing the small incisive foramina. The ears are rounded and short. *Eumops*, with numerous species, is found from southwestern United States to Argentina. They vary in size from large (4.43 in. head and body length) to medium (3.54 in.). The upper incisors are large, closely pressed together and procumbent, the skull is long and low with poorly developed sagittal crest. The cheek-teeth are generally $\frac{5}{5}$ on each side but the first upper premolar is sometimes absent. The ears are large, joined across the forehead, rounded or somewhat squarish and extending beyond the muzzle. *Molossus* is generally small, with short, rounded skull in which the sagittal crest is well developed. The first upper premolar is absent or a mere vestige, and the last upper molar is narrow, with a V-shaped crest. The other cheek-teeth are massive.

EXTINCT BATS



The frail skeletons of bats are rarely preserved as fossils but several deposits have yielded extremely fine specimens. The oldest forms come from the Eocene and even then showed most of their present-day structure; some were sufficiently different to be referred to separate families. Others were members of the Rhinolophidae. In a little later deposit representatives of the Megadermidae, Emballonuridae, Vespertilionidae and Molossidae were found. The first known pteropodid comes from the Oligocene of Italy. By the Pliocene most bat fossils can be referred to existing genera but even late Pleistocene deposits contain a few extinct genera and numerous extinct species.

(J. F. HL.)

CHIRU, a graceful Tibetan antelope (*Pantholops hodgsoni*), of which the bucks are armed with long, slender and heavily ridged horns of a peculiar type. Chiru are very wary and difficult to approach; they are generally found in small parties. They inhabit the desolate plateau of Tibet, at elevations of between 13,000 and 18,000 ft., and have a thick coat, formed of close woolly hair of a gray-fawn colour. The most peculiar feature about the chiru is its swollen, puffy nose, probably connected with breathing a rarefied atmosphere. The chiru is allied to the saiga (*q.v.*).

CHIRURGEON, one whose profession it is to cure disease by operating with the hand. The word in its original form is now obsolete. It derives from the Mid. Eng. *cirurgien* or *sirurgien*, through the Fr. from the Gr. words meaning *hand* and *work*; from the early form is derived the modern word "surgeon." "Chirurgeon" is a 16th century reversion to the Greek origin. (*See* SURGERY.)

CHISELS IN COMMON USE FOR CUTTING METAL, STONE OR WOOD USED IN CARPENTRY AND OTHER TRADES

CHISEL, a sharp-edged tool for cutting metal, wood or stone. There are numerous varieties of chisels used in different trades; the carpenter's chisel is wooden-handled with a straight edge, transverse to the axis and bevelled on one side; stone masons' chisels are bevelled on both sides, and others have oblique concave or convex edges. A chisel with a semicircular blade is called a "gouge." The tool is worked either by hand-pressure or by blows from a hammer or mallet. The "cold chisel" has a steel edge, highly tempered to cut unheated metal. The derivation is from O.Fr. *cisel*, modern *ciseau*, late Lat. *cisellum*, a cutting tool, from *caedere*, to cut. (*See* TOOL.)

CHISHOLM, HUGH (1866–1924), editor of the *Encyclopædia Britannica*, was born in London on Feb. 22, 1866. He was of Scottish descent, the son of Henry Chisholm, who became warden of the standards in the Board of Trade. Educated at Felsted school and Corpus Christi college, Oxford, of which he was a scholar, he graduated in 1888 with a first class in *literae humaniores*. He then read for the bar, being called at the Middle Temple in 1892, but occupied himself also with occasional journalism and finally adopted that profession. From 1892 to 1897 he was assistant editor, and from 1897 to the end of 1899 editor, of the *St. James's Gazette*, and during these years he also contributed numerous articles on political, financial and literary subjects to the weekly journals and monthly reviews, becoming known as a literary critic and Conservative publicist.

On resigning the editorship of the *St. James's*, he became a

leader writer for *The Standard,* and later, in 1900, was invited to join *The Times,* under whose management he acted as the responsible co-editor, with Sir Donald Mackenzie Wallace and President A. T. Hadley of Yale university, of the new volumes, constituting the tenth edition (1902), of the *Encyclopædia Britannica,* becoming in 1903 editor-in-chief of the 11th edition.

Rejoining *The Times* in 1913 as day editor, he became financial editor at the end of that year, and occupied this responsible position all through the momentous period of World War I, resigning his connection with *The Times* in March 1920, in order to reassume the editorship of the *Encyclopædia Britannica* and to organize the publication of the new volumes constituting the 12th edition. In 1893 Chisholm married E. Beatrix Harrison, of Ardkeen, County Down, Ireland, and had three sons. He died in London on Sept. 29, 1924.

CHISHOLM, a mining village of St. Louis county, Minn., U.S., on the Mesabi iron range, 75 mi. N.W. of Duluth. It is on federal highway 169 and is served by the Duluth, Missabe and Iron Range and the Great Northern railways. The population was 6,854 in 1950 and was 7,487 in 1940 by the federal census. The village was settled about 1901.

CHISLEHURST, a parish and, with Sidcup, an urban district of Kent, England, 11¼ mi. S.E. of London, by the S.R. Pop. (est. 1938) 61,750. Area 14 sq.mi. It is 300 ft. above sea level in the midst of a common of furze and heather. The church of St. Nicholas is Perpendicular with Early English portions, though much restored. The mortuary chapel attached to the Roman Catholic church of St. Mary was built to receive the body of Napoleon III, who died at Camden Place in 1873. This house was built by William Camden, the antiquary, in 1609. It was the residence of Napoleon III, of the empress Eugénie and of the prince imperial. In 1927 the National Trust secured 88 ac. of Pettswood as a memorial to William Willett, founder of "summer time."

CHISWICK: *see* BRENTFORD AND CHISWICK.

CHITA, a region, town and river in the Far Eastern area of the Russian Soviet Federated Socialist Republic. The area of the region is 277,992 sq.mi. and its population (1939) 1,159,478, urban 510,900 and rural 648,578. It consists of the southwestern tongue of the Far Eastern area lying between Mongolia and the Buriat Mongol A.S.S.R., and is thus a plateau area, with the southwestern portion of the Yablonoi mountains rising above the plateau. An island of territory on the southeastern slopes of the Yablonoi mountains, extending to the left bank of the Onon river, and crossed by the railway from Chita to Manchuria, belongs to the Buriat Mongol A.S.S.R. The subalpine conditions and the extreme continental character of the climate are unfavourable to agriculture except along the valleys of the Shilka and its tributaries, the Ingoda and Onon. Rye is the main crop, though oats, wheat, buckwheat, barley, grass and potatoes are also grown. Herding of horses, cattle, sheep and goats is, however, more important than cultivation, and only .9% of the region is ploughed land. But the essential wealth of the region is in its forests and minerals. Timber and fur (especially fox and squirrel) are exported, the latter being sent to the Irbit and Gorky fairs. The mineral wealth of the region is very great, gold is produced in quantity. Brown coal is mined, and used mainly for the railway and for the town of Chita, and iron ore is mined in quantity. It is almost the only area in U.S.S.R. where wolfram, bismuth and molybdenum are found. There are tin mines near the Onon river and precious stones, *e.g.,* crystal, topaz, aquamarine, amethyst, tourmaline and beryls occur. Mining in the area ceased during the civil war following the 1917 revolution, but most of the mines were working again after 1925. Much of the rolling stock of the railway was destroyed in this period and great damage done to the permanent way, and this hampered the reorganization of the mining industry. Manufactures are little developed, the chief being metal goods and leather. A few electric stations exist. The district is noted for contraband trade with Manchuria and Mongolia.

The town of Chita, lat. 52° N., long. 113° 25′ E. pop. (1939) 102,555, is on the Chita river above its confluence with the Ingoda. With the coming of the Trans-Siberian railway and the increasing exploitation of the mineral, timber and fur wealth of the region, the population and importance of the town developed. Its industries include iron founding, fur and leather dressing, soap boiling, chemical works and boxmaking. The Russian Geographical society has a museum in the town. The Dekabrists, exiled after the Dec. 1825 plot, by their improvements in draining and levelling, converted Chita from a village to a prosperous settlement.

CHITALDROOG, a district and town in the native state of Mysore, India. The district has an area of 4,022 sq.mi. and a population (1931) of 656,569. The rainfall is low, and the Vedavati or Hagari river, in whose valley the town lies, is mostly dry in the hot season. Several parallel chains of hills, reaching an extreme height of 3,800 ft., cross the district; otherwise it is a plain. The chief crops are cotton and rice, and manganese is worked. The west of the district is served by the Madras and Southern Mahratta railway. The largest town in the district is Davangere with cotton factories and a trade in cotton and grain. The town of Chitaldroog, which is the district headquarters (pop. 1941, 14,528) has a considerable trade in cotton. It possesses massive fortifications erected under Hyder Ali and Tippoo Sahib toward the close of the 18th century; and near it on the west are remains of a city of the 2nd century A.D. It is the terminus of a railway from Chikjajur.

CHITARRONE: *see* LUTE; THEORBO.

CHITIMACHA, a tribe of American Indians living on the shores of Grand lake and the banks of Grand river in Louisiana at the time the French settled that region. The Chitimachan linguistic group included three tribes: the Chitimacha, Washa and Chawasha. The name comes from the Choctaw: *chuti,* cooking pot, *masha,* they possess (they have cooking vessels). They called themselves *Pantchpinunukansh,* "men altogether red," a designation apparently made after the coming of the whites. War with the French over the murder of the missionary St. Cosme in 1706 was concluded by presentation of the head of the murderer. They were strict monogamists, and women evidently had authority in their government. What remains of the tribe is scattered.

CHITON, a genus of Amphineura (*q.v.*). (*See* also MOLLUSCA.)

CHITRAL, a native state in the North-West Frontier Province of India. The State of Chitral (*see* also HINDU KUSH) is somewhat larger than Wales, and supports a population of about 35,000 rough, hardy hillmen. Both the state and its capital are called Chitral, the latter being situated about 47 mi. from the main watershed of the range of the Hindu Kush, which divides the waters flowing down to India from those which take their way into the Oxus. The state is important because of its situation at the extremity of the country over which the government of India exerts its influence, and for some years before 1895 it had been the object of the policy of the government of India to secure an effective guardianship over its northern passes. This policy resulted in a British agency being established at Gilgit (Kashmir territory). Chitral can be reached either by the long circuitous route from Gilgit, involving 200 mi. of hill roads and the passage of the Shandur pass (12,250 ft.), or (more directly) from the Peshawar frontier at Malakand by 100 mi. of route through the independent territories of Swat and Bajour, involving the passage of the Lowarai (10,450 ft.). It is held by a small force as a British outpost.

The district of Chitral is called Kashgar by the people of the country. It was under Chinese domination in the middle of the 18th century, and was a Buddhist centre of some importance in the early centuries of our era. The aboriginal population is probably to be recognized in the people called Kho (speaking a language called Khowar), who form the majority of its inhabitants. Upon the Kho a people called Ronas, who form the chief caste and fighting race of the Chitral districts, have been superimposed; they came originally from the north, but have adopted the language and fashions of the conquered Chitrali. (X.)

The Siege of Chitral.—The town of Chitral is chiefly famous for a siege which it sustained in the spring of 1895. Owing to complications arising from the demarcation of the boundary of Afghanistan which was being carried out at that time, and the ambitious projects of Umra Khan, chief of Jandol, who was

tool in the hands of Sher Afzul, a political refugee from Chitral supported by the amir at Kabul, the mehtar (or ruler) of Chitral was murdered, and a small British and Sikh garrison subsequently besieged in the fort. A large force of Afghan troops was at that time in the Chitral river valley to the south of Chitral, nominally holding the Kafirs in check during the progress of boundary demarcation. It is considered probable that some of them assisted the Chitralis in the siege. The position of the political agent Dr. Robertson (afterward Sir George Robertson) and his military force of 543 men (of whom 137 were noncombatants) was at one time critical. Two forces were organized for the relief. One was under Sir R. Low, with 15,000 men, who advanced by way of the Malakand pass, the Swat river and Dir. The other, which was the first to reach Chitral, was under Colonel Kelly, commanding the 32nd Pioneers, who was placed in command of all the troops in the Gilgit district, numbering about 600 all told, with two guns, and instructed to advance by the Shandur pass and Mastuj. This force encountered great difficulties owing to the deep snow on the pass (12,230 ft. high), but it defeated the Chitrali force opposed to it and relieved Chitral on April 20, the siege having begun on March 4. Sher Afzul, who had joined Umra Khan, surrendered, and eventually Chitral was restored to British political control as a dependency of Kashmir. (T. H. H.)

CHITTAGONG, town and port of British India, giving its name to a district and division of Bengal. It is situated on the right bank of the Karnaphuli river, about 12 mi. from its mouth. It is the terminus of the Assam-Bengal railway and a port of call for the Clan line of steamers. The municipal area covers about 9 sq mi.; pop. (1941) 92,301. Tea is brought from Assam for export to Europe; mineral oil comes in bulk from Burma, is put into tins here and distributed by rail; other exports are jute, raw cotton, rice and hides.

The district of Chittagong occupies a strip of coast and hills between the Bay of Bengal and the mountains. Its area is 2,869 sq.mi.; in 1941 the population was 2,153,296. A few unimportant ranges rise within the northeastern portion, the highest hill being the sacred Sitakund, 1,155 ft. high. The principal rivers are the Karnaphuli, on which Chittagong town is situated, navigable by sea-going ships as far as Chittagong port, the Halda and the Sangu. The wild animals include tigers, elephants, leopards and deer. The northern portion of the district is traversed by the Assam-Bengal railway. Tea cultivation is moderately successful; there were 21 gardens with an output of 1,250,000 lb. in 1921. Chittagong was a famous seaport known to the Portuguese as Porto Grande, and described by de Barros in 1552 as "the most famous and wealthy city of the kingdom of Bengal"; it has been generally identified with the City of Bengala mentioned by Portuguese and other writers. Conquered by the Mohammedans in the 14th century, it passed under the rule of the Arakanese in the next century. The piratical raids of the Arakanese and their Portuguese mercenaries led to the despatch of a strong force by Shaista Khan, the Mughal Nawab of Bengal, which in 1666 captured the town and occupied the district. The Portuguese also had a settlement at Dianga, where 600 of them were massacred by the Arakanese in 1607. Chittagong was ceded to the East India company by Nawab Mir Kasim Ali in 1760.

The Chittagong Hill Tracts is an independent district occupying the hill country between Chittagong proper and the Lushai hills. The highest point is 4,034 ft. above sea level. Its area covers 5,007 sq.mi.; pop. (1941) 247,053. The inhabitants are either descendants of Arakanese or aboriginal tribes, such as Maghs, Tipperas and Chakmas: seven-tenths are Buddhists. The Hill Tracts are grouped in three circles, each under a chief, who is responsible for the collection of revenue and the internal management of the villages. The headquarters are at Rangamati, which was wrecked by a cyclone in Oct. 1897.

The division of Chittagong lies at the northeast corner of the Bay of Bengal, extending northward along the left bank of the Meghna. It consists of the districts of Chittagong, the Hill Tracts, Noakhali and Tippera. Its area covers 11,765 sq.mi.; the population in 1941 was 8,477,890.

CHITTOOR, a town and district of the Madras Presidency, British India. The district, which has an area of 5,951 sq.mi. and a population (1941) of 1,632,395, was formed in recent years from the northern part of North Arcot. It is in great part hilly, being traversed by spurs of the Eastern Ghats radiating east and south. The surface in the hill-country is rocky, save for patches of stunted jungle, but the narrow valleys between the hills are fertile, and the hills themselves are highly mineralized, showing copper and iron especially. The chief crops are rice, millet and oil-seeds. Chittoor (pop. 1941, 27,835) is the chief town, with a station on the Madras and South Mahratta railway, 100 mi. by road from Madras. It contains a native college, mission training school, a hospital and a sanatorium. There is a trade in granite, a distillery and a tannery, but Chittoor is not an important centre. Hyder Ali died here in 1782.

CHITTY, SIR JOSEPH WILLIAM (1828–1899), English judge, was born in London. He was the second son of Thomas Chitty, a celebrated special pleader and writer of legal text-books. Joseph Chitty was educated at Eton and Balliol college, Oxford, and elected to a fellowship at Exeter college. He became a member of Lincoln's Inn in 1851, was called to the bar in 1856, and made a queen's counsel in 1874, electing to practise in the court of the Master of the Rolls, Sir George Jessel, before whom he was very successful. In 1880 he entered the house of commons as Liberal member for Oxford (city); in 1881, however, he was selected to fill the vacancy in the chancery division caused by the elevation of the master of the rolls to the court of appeal by the Judicature Act. In 1897 he was promoted to the court of appeal.

See E. Manson, *Builders of our Law* (1904).

CHIUSI, a town of Tuscany, Italy, province of Siena, 55 mi. S.E. by rail from the town of Siena, and 26 mi. N.N.W. of Orvieto by the main line from Rome to Florence. Pop. (1936) 2,534 (town), 8,043 (commune). The ancient name was Clusium (*q.v.*). It is on a hill 1,305 ft. above sea level, and is surrounded by mediaeval walls, in which, in places, fragments of the Etruscan wall are incorporated. The cathedral of S. Secondiano is a basilica with eighteen ancient marble columns. It has fine choir books from Monte Oliveto Maggiore (*see* ASCIANO). Chiusi was devastated by malaria in the middle ages (*see* CHIANA). Nine miles by road to the northwest are the baths of Chianciano.

CHIVALRY, the knightly class of feudal times. (*See* KNIGHTHOOD AND CHIVALRY.) The primary sense in the middle ages is "knights" or "fully armed and mounted fighting men." Thence the term came to mean that gallantry and honour expected of knights. Lastly, the word came to be used in its general sense of "courtesy." In English law chivalry meant the tenure of land by knights' service. The *Court of Chivalry* was a court instituted by Edward III, of which the lord high constable and earl marshal of England were joint judges, having summary criminal jurisdiction as regards all offences of knights, and generally as to military matters. When the earl marshal alone presided it was a court of honour deciding as to precedence, coats of arms, etc. This court sat for the last time in 1737. The heraldic side of its duties is now vested in the earl marshal as head of the Heralds' college.

CHIVASSO, a town and episcopal see of Piedmont, Italy, province of Turin, 18 mi. N.E. by rail from that town, 600 ft. above sea level. Pop. (1936) 6,002 (town); 11,590 (commune). It is on the left bank of the Po, near the influx of the Orco. The cathedral (15th century) has a fine façade, with statues in terracotta. A tower remains of the old castle of the marquesses of Monferrato, who possessed the town from 1164 to 1435. It was an important fortress in the middle ages and until the French dismantled it (1804). Chivasso is the junction of branches for Aosta, Asti, and Casale Monferrato.

CHIVES (*Allium Schoenoprasum*), hardy perennial plant, with small narrow bulbs tufted on short root-stocks and long cylindrical hollow leaves. It is found in the north of England and in Cornwall, growing in rocky pastures throughout temperate and northern and in the mountain districts of southern Europe and in Asiatic Russia. It is cultivated for its leaves, which are used in salads and soups as a substitute for young onions; it will grow in any good soil.

CHLOPICKI, GREGORZ JOZEF (1772–1854), Polish general, was born in Podolia. In 1787 he enlisted in the Polish army and fought in the campaigns of 1792–94. He served with the new Italian legion at the storming of Peschiera, at Modena, Busano, Casabianca and Ponto, and in 1807 commanded the first Vistula regiment. In Spain he obtained the Legion of Honour for his heroism at Epila and the storming of Saragossa. Chlopicki accompanied the Grande Armée into Russia (1812). On the reconstruction of the Polish army in 1813 he was made a general of a division, afterward joining the Russian army with the rank of general officer.

He held aloof at first from the Polish national rising of 1830, but at the request of his countrymen he accepted the dictatorship on Dec. 5, 1830. Lacking faith in the success of the movement, he clung to the hope of negotiation with Russia and acted purely on the defensive. On Jan. 17, 1831, he resigned and became a private, until he was forced to retire into private life owing to serious wounds received at Olszyna.

See Josef Maczynski, *Life and Death of Joseph Chlopicki* (Pol.) (Cracow, 1858); Ignacy Pradzynski, *The Four Last Polish Commanders* (Pol.) (Posen, 1865).

CHLORAL or TRICHLOROACETALDEHYDE, first prepared by J. von Liebig in 1832, is a heavy, oily and colourless liquid, of specific gravity 1.541 at 0° C., boiling point 97.7° C., and the formula $CCl_3.CHO$. It has a greasy, somewhat bitter taste and gives off a vapour at ordinary temperature which has a pungent odour and an irritating effect on the eyes. The word "chloral" is derived from the first syllables of "chlorine" and "alcohol," the names of the substances employed for its preparation. Chloral is soluble in alcohol and ether, in less than its own weight of water and in four times its weight of chloroform. It deliquesces in the air and is converted by water into a hydrate, with evolution of heat; it combines with alcohols and mercaptans. With an alkali, chloral gives chloroform (*q.v.*) and a formate; oxidizing agents give trichloroacetic acid, $CCl_3.CO_2H$. When kept for several days, as also when placed in contact with sulphuric acid or a very small quantity of water, chloral undergoes spontaneous change into the polymeride metachloral $(C_2HCl_3O)_x$ of uncertain molecular weight and structure, a white substance slowly volatile in the air and reconverted into chloral without melting at 180° C. Two different, and presumably stereoisomeric parachlorals, $(C_2HCl_3O)_3$, having also been reported to be formed by the action of sulphuric acid upon chloral.

Chloral is prepared by passing dry chlorine into cooled absolute alcohol; toward the end of the operation the liquid is heated nearly to boiling. The alcohol is converted finally into a syrupy fluid, from which chloral is procured by treatment with sulphuric acid (P. Fritsch, 1894). The crude chloral is distilled over lime and is purified by further treatment with sulphuric acid and by redistillation. A mixture of starch or sugar with manganese peroxide and hydrochloric acid may be employed instead of alcohol and chlorine (A. Staedeler, 1847).

Chloral hydrate, $CCl_3.CH(OH)_2$, forms oblique rhombic prisms, perfectly transparent and only slightly odorous. The melting point of pure chloral hydrate is 57°, the boiling point 96°—98° C. When heated with sulphuric acid it is converted into anhydrous chloral and chloralide, $C_5H_2Cl_6O_3$. When mixed with water, chloral hydrate causes a considerable degree of cold; and, as with camphor, small fragments of it placed on the surface of water exhibit gyratory movements. Chloral hydrate does not restore the colour to a solution of fuchsine decolorized by sulphurous acid; this absence of aldehydic property indicates that the water present is combined in the molecular condition. Chloral may be estimated by distilling the hydrate with aqueous calcium hydroxide and measuring the volume of chloroform produced, or by hydrolysis with a known volume of standard alkali and back titration with standard acid. Chloral hydrate has the property of checking the decomposition of many albuminous substances, such as milk and meat; and a mixture with glycerin, according to J. Personne, is suitable for the preservation of anatomical preparations.

Pharmacology and Therapeutics.—The alkaline hydrolysis of chloral hydrate, with production of chloroform and formates, led O. Liebreich to the conjecture that a similar decomposition might be produced in the blood, and he introduced the drug in 1869 as an anaesthetic and hypnotic. It later became known, however, that the drug circulates in the blood unchanged and is excreted as urochloralic acid. In large doses chloral hydrate is a depressant to the circulation and the respiration, and also lowers the temperature. In therapeutic dosage the drug is a powerful and safe hypnotic, acting directly on the brain and producing no preliminary stage of excitement. About 20 minutes after taking such a dose, the patient falls into a refreshing sleep which, lasting several hours, is not distinguishable from natural sleep and is without disagreeable after-symptoms. Chloral hydrate rapidly induces a depression of the anterior horns of gray matter in the spinal cord, and, as strychnine poisoning is accompanied by violent stimulation of these areas, chloral hydrate is a valuable antidote in such cases. It should not be hypodermically injected since it is irritating to the tissues. It can be applied locally as a rubefacient. Its action on the spinal cord has been employed with success in cases of tetanus, whooping cough, urinary incontinence and strychnine poisoning. It is used by doctors to allay spasms in infancy and childhood and also in certain complications of pregnancy and labour.

Toxicology.—In cases of acute poisoning by chloral hydrate, the symptoms may be summarized as those of profound coma. The treatment is to give gastric lavage, to keep up the temperature by hot bottles, etc., and to use artificial respiration in extreme cases. Strychnine injections are much less likely to save life after poisoning by chloral hydrate than chloral hydrate is to save life in poisoning by strychnine. Metrazol and ephedrine may be useful.

Habitual use of chloral as a drug results in chronic poisoning. The victim is usually excited, loquacious, easily fatigued and suffers from attacks of readily induced syncope. The patient may succumb to a dose only slightly larger than usual. There is no specific remedy; the patient must be persuaded to put himself under restraint, and the drug must be stopped at once and entirely.

CHLORATES: *see* CHLORINE.

CHLORINE, a chemical element of the halogen (*q.v.*) family. This strong-smelling, greenish-yellow gas was first prepared in 1774 by K. W. Scheele from muriatic (hydrochloric) acid (HCl) and pyrolusite (MnO_2); it was then known as dephlogisticated muriatic acid. C. L. Berthellot, believing that the muriatic acid had combined with the oxygen from the pyrolusite, called it oxymuriatic acid. Because he was unable to decompose it, H. Davy (1810) contended that the so-called oxymuriatic acid was an element and showed further that muriatic acid itself contains only hydrogen and the new element, chlorine. Hence in its reaction with pyrolusite, muriatic acid loses hydrogen rather than gains oxygen. Davy's views eventually prevailed, chlorine was accepted as an element, and Antoine Lavoisier's theory that all acids contain oxygen was discarded. The name "chlorine" is taken from the greenish-yellow (Greek χλωρός) colour of the gas.

Chlorine is never found uncombined in nature. Estimated to account for 0.15% of the earth's crust, it occurs most abundantly in soluble chlorides, such as sodium chloride in salt water and rock salt, and in smaller quantities in such insoluble materials as horn silver (AgCl). Chlorine as chloride is an essential constituent of animal life.

Preparation.—The element may be prepared on a laboratory scale by treatment of hydrochloric acid, or any soluble chloride in acid solution, with strong oxidizing agents such as manganese dioxide, potassium permanganate or potassium dichromate. Concentrated sulphuric acid, however, will not liberate chlorine. The essential change in the preparation of the element from chloride is the removal of an electron from the chloride ion, $2\bar{C}l \rightarrow Cl_2 + 2e$. Chlorine may also be prepared by the reaction of a hypochlorite with an acid. Since chlorine is readily available in cylinders of various sizes, preparation in the laboratory is of little practical importance. (For the preparation of chlorine on a large scale, *see* section *In Industry*, below.)

Physical Properties.—Chlorine, having an atomic weight of 35.457, is a mixture of two isotopes of weights 35 and 37, 24.6% of its atoms being the heavier isotope. The radioactive isotopes Cl_{33},

half life 2.4 sec.; Cl^{34}, half life 33 min.; Cl^{36}, half life $>10^8$ years; and Cl^{38}, half life 37 min., have been made artificially. All atoms have the electron configuration: $1s^2$, $2s^2$, $2p^6$, $3s^2$, $3p^5$. The atom has a high affinity, 3.75 ev, for an additional electron, the acquisition of which gives it a complete external octet and a charge of -1 as chloride ion. The chloride ion in crystals has a radius of 1.81 Å. Elementary chlorine in the vapour state consists of diatomic molecules, of molecular weight 70.91. The density of the gas at 0° C. and 1 atm. is 3.214 g. per litre, 1.6% greater than the density corresponding to a molecular weight of 70.91. At 1,000° C. less than 0.01% of the molecules dissociate. Chlorine boils at −34.7° C. at 1 atm., freezes at −102° C., its critical temperature is 184° C., critical pressure 76.1 atm. and critical density 0.573 g./ml. The vapour pressure of liquid chlorine in atmosphere at T° Kelvin is $\log P = -1{,}499.5/T - 4.022 \log T + 15.844$. The heat of fusion of chlorine is 22.9 cal./g., the heat of vaporization 62.2 cal./g. The heat capacity of chlorine gas at constant pressure is 0.226 cal./g. at room temperature. $8.28 + 0.56 \times 10^{-3} T$ cal./mol. at T° K. and of liquid chlorine 16 cal./mol. The entropy at 298.1° K. is 53.31 cal./mol./degree. The gas is moderately soluble in water, at 20° C. to the extent of 0.09 mol./litre at 1 atm.

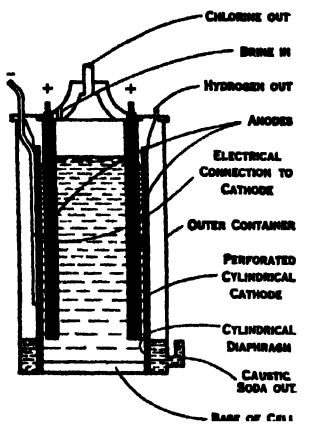

FIG. 1.—CYLINDRICAL DIAPHRAGM CELL

Hydrogen is set free at the perforated cathode as the brine percolates through it, leaving caustic soda in solution. The chlorine is set free at the carbon anodes

Chemical Properties.—Chlorine is a member of Group VII of the periodic system. While it is essentially an electronegative element, tending to go to the chloride ion of oxidation state −1, chlorine is also known in the +1, +3, +4, +5 and +7 states of oxidation. Chlorine combines directly with all but a few elements; oxygen, fluorine, nitrogen, carbon and the inert gases being exceptions. The binary compounds thus formed are called chlorides (*see* HYDROCHLORIC ACID AND HYDROGEN CHLORIDE). Many of these reactions occur at room temperature; *e.g.*, with powdered antimony $2Sb + 3Cl_2 = 2SbCl_3$. If free from moisture, chlorine is much less reactive, and higher temperatures are required for reaction, thus permitting the storage of dry liquid chlorine in steel cylinders. Chlorine reacts at high temperatures with certain oxides in the presence of carbon to form chlorides; *e.g.*,

$$Al_2O_3 + 3Cl_2 + 3C = 2AlCl_3 + 3CO.$$

With water at 0° C., chlorine forms a crystalline hydrate, $Cl_2.8H_2O$, which decomposes on warming. This compound is of historical interest for, while experimenting with the hydrate, Michael Faraday in 1823 discovered that chlorine became liquid under pressure at low temperatures and later succeeded in liquefying a number of other substances which were previously known only in the gaseous state. A solution of chlorine in water contains a small amount of hydrochloric and hypochlorous acid because of the reversible reaction,

$$Cl_2 + H_2O = H^+ + \bar{Cl} + HOCl,$$

$K = 4.8 \times 10^{-4}$ at 25° C. Since the hypochlorous acid slowly loses its oxygen, the solution of chlorine in water is unstable, the chlorine eventually being all transformed to hydrochloric acid. Chlorine is readily absorbed in basic solutions, for the neutralization of the hydrochloric and hypochlorous acids prevents equilibrium being established. The reaction at room temperatures may be represented by

$$Cl_2 + 2O\bar{H} = \bar{Cl} + O\bar{Cl} + H_2O,$$

thus producing a mixture of chloride and hypochlorite (*see* BLEACHING POWDER). In hot concentrated alkali, chlorine forms chloride and chlorate,

$$3Cl_2 + 6O\bar{H} = 5\bar{Cl} + \bar{ClO_3} + 3H_2O.$$

Chlorine is a strong oxidizing agent. In aqueous solution the electrode potential

$$\tfrac{1}{2}Cl_2(g) + e = \bar{Cl}$$

is 1.358 v. at 25° C. Hence chlorine displaces bromine and iodine, which have lower potentials, from bromides and iodides. In aqueous solution chlorine oxidizes and is itself reduced to chloride by such ions as sulphide, thiosulphate, sulphite, ferrous and stannous. Chlorine combines with carbon monoxide to form carbonyl chloride (phosgene), $COCl_2$; with sulphur dioxide to form sulphuryl chloride, SO_2Cl_2; and with nitric oxide to form nitrosyl chloride, NOCl. Many organic compounds are chlorinated by chlorine. Hydrocarbons react with chlorine, by addition of chlorine to double bonds, or substitution of hydrogen by chlorine. In some cases, as with turpentine, the reaction is violent, all the hydrogen is removed as hydrogen chloride, and a residue of carbon is left.

Chlorine is an active poison and was the first gas used in chemical warfare in World War I. It causes suffocation, constriction in the chest, tightness in the throat and oedema of the lungs after severe exposure. As little as 2.5 mg. per litre in the atmosphere causes death in a few minutes, but less than 0.0001% by volume may be tolerated for several hours. Its strong odour, however, gives warning of its presence at much lower concentrations than are dangerous.

Oxides of Chlorine.—Four oxides, chlorine monoxide (Cl_2O), chlorine dioxide (ClO_2), chlorine hexoxide (Cl_2O_6) and chlorine heptoxide (Cl_2O_7), are known. ClO_4 or Cl_2O_8 has been made in solution by the reaction of iodine with silver perchlorate dissolved in benzene. All the oxides are unstable and reactive and cannot be produced by direct synthesis. Chlorine monoxide is made by the reaction of chlorine with mercuric oxide,

$$HgO + 2Cl_2 = HgCl_2 + Cl_2O.$$

In an industrial process chlorine monoxide is formed by the reaction of chlorine on solid sodium bicarbonate,

$$2Cl_2 + 2NaHCO_3 = Cl_2O + 2NaCl + 2CO_2 + H_2O.$$

It is slightly darker yellow than chlorine, condensing to a liquid at 2° C. and solidifying at −116° C. Chlorine monoxide is the anhydride of hypochlorous acid, readily dissolving in water to form the acid,

$$Cl_2O + H_2O = 2HClO.$$

Chlorine dioxide is formed by the action of strong acids on chlorates, best with oxalic acid,

$$2KClO_3 + 3H_2C_2O_4 = 2ClO_2 + 2H_2O + 2CO_2 + 2KHC_2O_4.$$

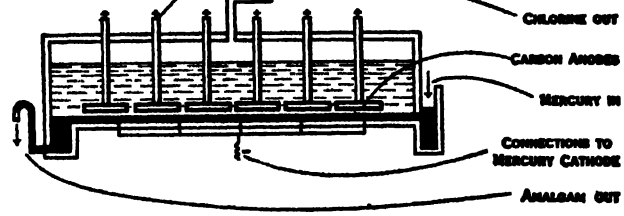

FIG. 2.—PRINCIPLES OF A MERCURY CELL

Mercury enters the cell at one end, propelled by a mechanical device. Brine flows through the cell in the same direction as the mercury (entrance and exit not shown). The mercury-sodium amalgam formed by the electrolysis leaves the cell and travels to a separate chamber in which it is brought into contact with water. After extraction of the sodium, the mercury returns to the cell and repeats the cycle

In the industrial preparation of sodium chlorite, chlorine dioxide is first formed by the reaction of hydrochloric acid on calcium chlorate,

$$Ca(ClO_3)_2 + 4HCl = CaCl_2 + 2Cl\bar{O}_2 + Cl_2 + 2H_2O,$$

the accompanying chlorine being removed by absorption on lime.

Chlorine dioxide decomposes explosively to Cl_2+O_2. It is a gas with a much stronger yellow colour than chlorine, liquefying at 10° C. and solidifying at −76° C. It is not an acid anhydride, hardly reacting with water and but slowly with alkalies to give a mixture of chlorite and chlorate. Chlorine hexoxide, formed by the action of light or ozone on chlorine dioxide, is a red oil, freezing at −1° C., decomposing slowly at higher temperatures. Chlorine heptoxide, the anhydride of perchloric acid, is formed by removal of water from that acid by phosphorus pentoxide. It is a colourless liquid boiling at 80° C. and freezing at −91.5° C. It explodes with shock.

Hypochlorous Acid and Hypochlorites.—In these compounds chlorine exists in the +1 state of oxidation. Hypochlorous acid, HOCl, is quite weak, $K=4\times10^{-8}$ at 25° C., and unstable, decomposing to hydrochloric acid and oxygen. The hypochlorite ion is stable in alkaline solution. Hypochlorites are formed in solution by the neutralization of hypochlorous acid or by the absorption of chlorine monoxide or chlorine by alkaline solutions. If chlorine is employed an equivalent amount of chloride is formed along with the hypochlorite. Because of the weakness of hypochlorous acid, hypochlorites are considerably hydrolyzed and preparation of the pure salts is difficult. Only a hydrated calcium hypochlorite, $Ca(OCl)_2.2H_2O$, is available in solid form, although solid sodium hypochlorite has been prepared. Sodium and calcium hypochlorite are widely used in bleaching and disinfecting, their effectiveness being attributed to their oxidizing powers. They are also effective oxidizing agents in preparative chemistry, lead dioxide for example being formed from lead acetate by the action of sodium or calcium hypochlorite in basic solution.

Chlorous Acid and Chlorites.—Salts of chlorous acid, $HClO_2$, are called chlorites and contain the ion $\overline{ClO}_2$, in which chlorine is in the +3 oxidation state. Sodium chlorite is made by passing chlorine dioxide into alkaline solution containing carboniferous material,

$$4ClO_2+4NaOH+Ca(OH)_2+C=4NaClO_2+CaCO_3+3H_2O.$$

Chlorites are generally soluble and stable in alkaline solution. Chlorous acid, although somewhat stronger than hypochlorous acid, is much less stable, and on acidifying a solution containing a chlorite, decomposition to ClO_2 occurs rapidly. Sodium chlorite is employed in bleaching.

Chlorates and Chloric Acid.—Chlorine in the +5 oxidation state occurs in chloric acid and its salts the chlorates. Chlorates

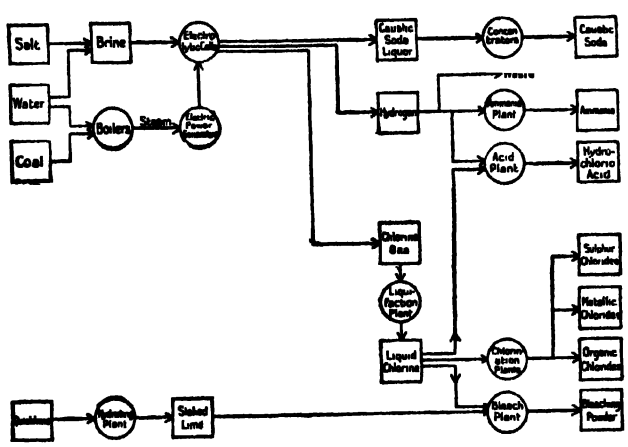

FIG. 3.—THE MANUFACTURE OF CHLORINE AND ITS DERIVATIVES

The diagram shows, from left to right the manufacture of chlorine from salt, water and coal, the principal industrial compounds formed and the commercial utilization of the by-products

are formed in solution by the reaction of chlorine with hot alkalies, or on mixing, at the proper temperature, the anode and cathode solutions resulting from electrolysis of sodium chloride solution. The chlorate is generally separated from the accompanying chloride by crystallization of the potassium salt which is only moderately soluble, but other chlorates may be made by either of these methods. A solution of chloric acid ($HClO_3$) may be prepared by adding sulphuric acid to a solution of barium chlorate and filtering to remove the precipitated barium sulphate. By evacuating at room temperature the solution may be concentrated to about 50% $HClO_3$, but in more concentrated solution decomposition is rapid. Chloric acid is a strong acid, hence chlorates are not hydrolyzed in solution. Chlorate ion is stable in neutral or basic solution, but in acid solution chlorates are readily reduced to chloride by such reagents as sulphur dioxide. Potassium chlorate, a white crystalline material melting at 350° C., is unstable with respect to the decomposition $2KClO_3=2KCl+3O_2$, and other chlorates decompose similarly. This reaction is highly exothermic and irreversible, but the decomposition is relatively slow below 400° C. It is markedly susceptible to catalysts; a mixture of potassium chlorate and manganese dioxide decomposes smoothly at moderate temperatures and serves as a source of small amounts of oxygen in the laboratory. A mixture of potassium chlorate and a reducing material such as charcoal or sulphur is dangerously explosive. Because they serve as a concentrated source of oxygen, chlorates are employed in fireworks, matches, etc. Potassium chlorate is claimed to be an effective antiseptic in the treatment of ulcers of the mouth, but in larger quantities is definitely poisonous. Sodium chlorate is sold commercially for use as a weed killer.

Perchlorates and Perchloric Acid.—In these compounds chlorine is in its highest oxidation state, +7. Potassium perchlorate may be made by carefully heating the chlorate,

$$4KClO_3=3KClO_4+KCl,$$

and separating the perchlorate, which is less soluble than either the chloride or chlorate, by crystallization. Commercially, however, it is made by electrolysis of chlorate solutions at high current density. The perchlorates in general are soluble, their solutions are stable, and even in strongly acid solution are reduced with difficulty. A perchlorate may be distinguished from a chlorate by treating in acid solution with sulphur dioxide, which reduces the latter readily but does not affect the perchlorate. Barium and magnesium perchlorates form stable hydrates and are employed as drying agents to remove moisture from gases. Perchloric acid is made by treatment of potassium perchlorate with sulphuric acid and separation of the perchloric acid by vacuum distillation. While perchloric acid is much more stable than chloric acid, the pure acid decomposes slowly at 92° C. At ordinary temperatures perchloric acid is a liquid with a strong affinity for water. It forms a stable hydrate, $HClO_4.H_2O$, which is a solid below 50° C. although the anhydrous acid only freezes at −112° C. It is commonly sold in 60% solution and finds application in analytical chemistry. It is one of the strongest acids. The concentrated acid is a powerful oxidizing agent and in contact with reducing materials violently explosive, as are the solid perchlorates at higher temperatures. Solid perchlorates lose oxygen on heating as do the chlorates but are somewhat more stable. They may be used in place of chlorates in explosives and fireworks, as they are considered safer to handle.

IN INDUSTRY

Almost since its discovery chlorine has been produced on a large scale for use in industry. The long-obsolete Weldon process was first employed, making use of the reaction of hydrochloric acid with manganese dioxide,

$$MnO_2+4HCl=Cl_2+MnCl_2+2H_2O,$$

by which K. W. Scheele first discovered chlorine. At best, only about one-third of the hydrochloric acid is transformed to chlorine in the process, and the lack of materials in which these corrosive substances could be handled made the Weldon process difficult and expensive. About 1868 Henry Deacon developed a process by which chlorine was made by the reaction of hydrogen chloride gas and atmospheric oxygen. The reaction employed,

$$4HCl+O_2=2Cl_2+2H_2O,$$

is reversible and incomplete. The rate of reaction was found to be satisfactory when the gases were passed over pumice in contact with cupric chloride, a catalyst, at about 430° C. Under these

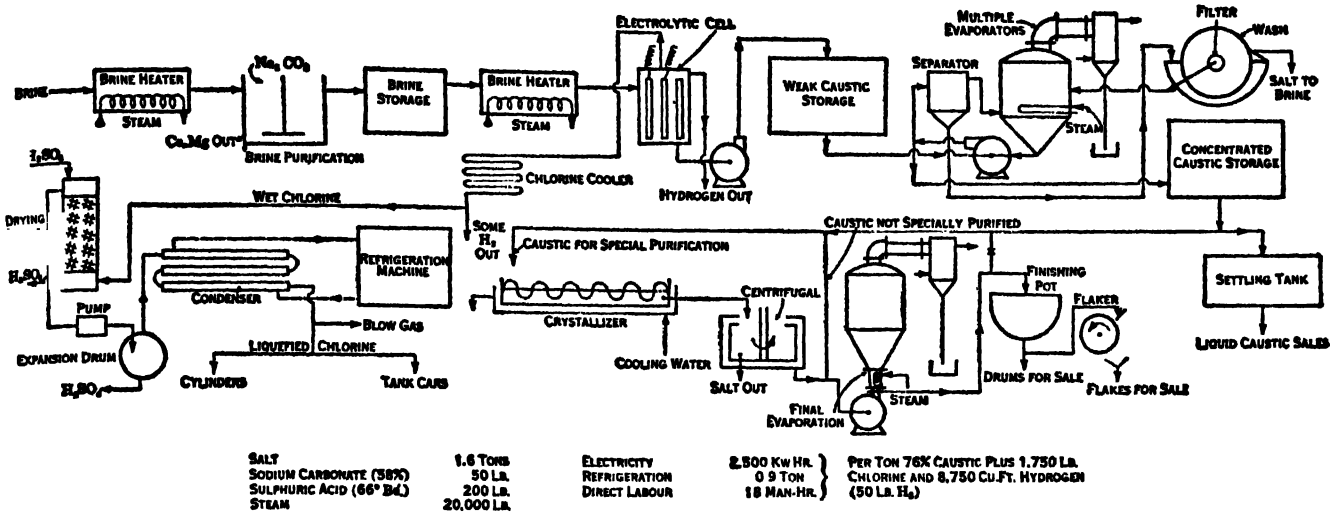

FIG. 4.—ELECTROLYTIC CAUSTIC SODA AND CHLORINE
Flow sheet showing the several stages from brine, the raw material, to caustic soda and chlorine, the products

conditions about 70% of the hydrogen chloride could be converted to chlorine. The hydrogen chloride required in the Deacon process was largely a by-product of the LeBlanc soda process (*see* ALKALI MANUFACTURE). With the decline of the latter, the Deacon process was abandoned, and electrolytic methods became the sole source of industrial chlorine.

Electrolytic chlorine was first produced successfully on a commercial scale about 1890. The following half century saw an enormous increase in the amount of chlorine produced. Technical improvements greatly increased the efficiency of production, but the process remained basically unchanged. The raw materials are salt (NaCl) and water; the products chlorine, sodium hydroxide (alkali or caustic soda) and hydrogen. The change which is brought about by electrical energy may be represented by

$$2NaCl + 2H_2O = Cl_2 + 2NaOH + H_2$$

salt water chlorine sodium hydroxide hydrogen

Although the electrolysis of salt produces equivalent amounts of both chlorine and caustic soda, the chlorine is regarded as the primary product and the caustic soda a by-product because, without a market for chlorine, the caustic soda so produced cannot compete economically with caustic from the ammonia-soda process.

Two distinct types of cell are employed, the diaphragm cell (fig. 1) and the mercury cell (fig. 2). In both, the electrolyte is a strong solution of salt (brine). Calcium and magnesium ions are precipitated from the brine before it enters the cell by addition of sodium carbonate, since these ions would otherwise precipitate in the cell and interfere with its operation. Both types employ graphite anodes but differ in the cathode material. Iron cathodes are generally used with the diaphragm-type cell, while a mercury cathode is the distinct feature of the mercury-type cell. In electrolysis of sodium chloride solution, the reaction at a graphite anode is the liberation of chlorine gas,

$$2\bar{C}l = Cl_2 + 2e.$$

Small amounts of oxygen usually accompany the chlorine, thus reducing the efficiency of operation (*see* ELECTROCHEMISTRY). At an iron cathode, hydrogen is discharged. Discharge of sodium does not occur in the presence of water, for the potential required to discharge sodium is much greater than that at which hydrogen is set free. The hydrogen comes from the water, leaving hydroxyl ion in solution,

$$H_2O + 2e = H_2 + 2\bar{O}H.$$

The cathode and anode solutions must be kept separate for, with chlorine formed at the anode and sodium hydroxide at the cathode, mixing of the solutions would result in the formation of hypochlorite instead of evolution of chlorine. The diaphragm, commonly made of asbestos paper, serves this purpose. The diaphragm is adjacent to, and supported by, the cathode. Later practice favoured the nonsubmerged diaphragm, where the brine seeps through the diaphragm and is electrolyzed, and the alkaline solution trickles to the bottom of the cell. The cathode liquors average 110 to 120 g. NaOH per litre and 140 to 170 g. NaCl per litre. An outlet above the cathode allows the hydrogen to escape or to be collected. The anode section generally has a concrete cover with an opening for collection of the chlorine. Some of the diaphragm-type cells in common use at mid-20th century were the rectangular Allen-Moore and Hooker type S (U.S.), the Hargreaves-Bird (British), Krebs (French), Billiter (German) and the cylindrical Vorce (U.S.). The bell jar cell, without diaphragm and with a slowly streaming electrolyte, has been employed in Europe.

Factors influencing the design of cells are the initial cost, life period, purity of product and efficiency with which electrical energy is utilized. Theoretically, the decomposition of aqueous sodium chloride solution requires about 2.2 v., but in operation the voltage drop per cell is found to be from 3.3 to 4.5 v. Hence, although the current efficiency in the modern cell is more than 90%, the energy efficiency is only 50%–60%. The excess voltage required results from energy lost as heat because of the resistance of the electrolyte, which may be minimized by having large electrodes close together, and to overvoltage effects at the electrodes. The overvoltage is largely a property of the electrode material, in the choice of which resistance to chemical action and cost must be considered. The commoner types of cell operate at 1,000–5,000 amp., but the current density in amperes per square inch of electrode surface is only 0.12–0.50. An average yield per kilowatt hour is about two-thirds pound of chlorine and the same weight of sodium hydroxide. The different types of cell vary considerably in size, from the cylindrical Vorce cell, only 26 in. in diameter, to the Billiter cell, 18 ft. long, 10 in. wide and 2 ft. deep.

The operation of the diaphragm-type cell is accompanied by decreased efficiency because of the clogging of the diaphragm, which must be renewed at intervals of from one month to a year, varying with the different types of cell. In the Hargreaves-Bird cell, steam and carbon dioxide enter the cathode compartment, changing the sodium hydroxide to sodium carbonate. The diaphragm in this cell has a long life which is attributed to the action of the steam.

In the mercury-type cell sodium is discharged into the mercury cathode at the bottom of the cell, and no hydrogen is evolved. Mechanical agitation moves the amalgamated mercury to a separate compartment of the cell where it is made the anode, causing the sodium to go back into solution as sodium hydroxide, while hydrogen is discharged from an ion cathode above. The over-all reaction is the same as with the ion cathode-type cell. The advantage of the mercury-type cell is that the caustic soda solution is free from

chloride and may be produced at as high as 50% concentrate in the cell, while in the other cells the caustic soda is more dilute and considerable chloride must be separated to prepare the sodium hydroxide for sale. The disadvantage of the mercury-type cell is the high cost of the mercury. The efficiencies reported are about the same as for the diaphragm-type cell. The cells are operated with much greater currents, however, up to 15,000 amp. The original mercury-type cells were developed by H. Y. Kastner (U.S.) and C. Kellner (Austria). Modern versions are the Sorenson and Krebs cells.

A 1945 report from Germany stated that all new installations since 1936 had been of mercury-type cells, presumably because of lower power costs and a plentiful supply of mercury from Spain. The new-type cells are steel tanks from 20 to 40 ft. long, 25 in. wide and 8 in. deep. The sides are coated with rubber, and a thin layer of mercury on the bare steel bottom serves as cathode. The tank slopes to give a mercury flow such that 0.2% of sodium is accumulated at 15,000 amp. The sodium is stripped from the mercury by the action of water, without electrolysis, in an adjoining compartment. Brine, entering with 310 g. of NaCl per litre, is electrolyzed at from 70° to 90° C. and leaves the cell with 220–270 g. of salt per litre. The loss of mercury is reported to be from 1% to 7% per year.

Chlorine from the cells is freed from moisture by the action of concentrated sulphuric acid, cooled and liquefied by compression. The liquefied chlorine is sold in steel cylinders and tank cars. The large chlorine-caustic soda plants are generally located at points where both salt and electrical power are cheapest. However, some paper mills and rayon manufacturers, which are large users of both chlorine and caustic soda, run their own electrolytic plants. In this case the chlorine need not be liquefied and may be piped directly to the point of use. Chlorine produced as a by-product of the preparation of metallic sodium by the electrolysis of fused sodium chloride is a minor source of chlorine for industry.

Uses.—Originally the only large consumers of chlorine were the paper and textile industries, and most of the chlorine produced was consumed in the manufacture of bleaching powder for their uses. (*See* BLEACHING; BLEACHING POWDER.) Early in the 20th century began the shipment and use of liquid chlorine, which could be used directly in bleaching, and the proportion used in the manufacture of bleaching powder declined. Chlorine is an effective germicide, and chlorination of municipal water supplies has become general. In some instances chlorine is used to disinfect sewage. The rise of the rayon industry, which employs chlorine for the bleaching of pulp, provided a major outlet for industrial chlorine. Although the amount of chlorine employed for bleaching and disinfecting was undoubtedly increasing, the fraction of the total chlorine production going into this field was declining because of the tremendous increase in the amount of chlorine consumed by the chemical industry.

Chlorine has become widely used in the production of both organic and inorganic chemicals (fig. 3). Chlorine reacts with carbon disulphide to form carbon tetrachloride and sulphur chloride,

$$CS_2+3Cl_2=CCl_4+S_2Cl_2.$$

Carbon tetrachloride is largely used as a solvent, in fire extinguishers and in dry cleaning. Sulphur chloride, also made by combining sulphur and chlorine, is used in the vulcanization of rubber and as a chlorinating agent in organic syntheses. Sulphur chloride was used in the preparation of mustard gas, an important chemical warfare agent in World War I. Another important chlorinating agent, thionyl chloride ($SOCl_2$), is made by the reaction of chlorine, sulphuric acid and sulphur chloride. Thionyl chloride is used to form the acid chlorides of organic acids, which are valuable intermediates in organic syntheses. Chlorine combines with phosphorus to form phosphorus trichloride (PCl_3), which may be oxidized by potassium chlorate to phosphorus oxychloride ($POCl_3$), which is another useful chlorinating agent in forming acid chlorides from organic acids. Chlorine and carbon monoxide form carbonyl chloride, or phosgene ($COCl_2$), which has been employed in chemical warfare and is also used in metallurgy to transform certain oxides to chlorides.

A number of metallic chlorides are prepared with the use of chlorine. Anhydrous aluminum chloride is made by the reaction of chlorine with scrap aluminum or with aluminum oxide and carbon. It is used in the petroleum industry and as a catalyst for many organic syntheses. Anhydrous ferric chloride, made similarly, is employed in water clarification. Chlorine is used in the preparation of silicon chloride, from which the silicon synthetics are prepared. Silicon chloride and titanium chloride are used in forming smoke screens. Magnesium chloride ($MgCl_2$) is fused and electrolyzed for the production of metallic magnesium; zinc chloride ($ZnCl_2$) is an essential constituent of dry batteries. Stannic chloride ($SnCl_4$) is used in the textile trade. Its volatility is the basis for a method of recovery of tin from used tin plate.

Chlorine enters directly or as an intermediate into many organic syntheses of industrial importance. Chlorination of organic materials may be done at low temperatures with liquids or in the vapour phase at higher temperatures; the reactions may or may not require a catalyst. Since most organic materials may be chlorinated at different points on the molecule, or to different degrees, the conditions of chlorination must be carefully controlled. For example, the chlorination of a compound containing a benzene nucleus with an aliphatic side chain occurs in the benzene nucleus when the temperature is low in the presence of certain catalysts, but in the side chain at elevated temperatures or in the presence of sunlight.

Of the chlorinated derivatives of methane (CH_4), carbon tetrachloride (CCl_4) has been mentioned. Chloroform ($CHCl_3$) is used as a solvent and in medicine. Methyl chloride (CH_3Cl) is used as a refrigerant. Dichlor-difluoro-methane (CCl_2F_2), known as freon, is used as a household refrigerant. Ethyl chloride (C_2H_5Cl), a derivative of ethane (C_2H_6), is used in the production of lead tetraethyl. Unsaturated hydrocarbons, such as acetylene, combine directly with chlorine to form liquids such as acetylene tetrachloride ($CHCl_2$-$CHCl_2$) which are largely used as solvents and in dry cleaning.

Chlorinated aromatics serve as intermediates in the dye industry. Chlorobenzene (C_6H_5Cl) is hydrolyzed to produce phenol (C_6H_5OH). The insecticide DDT is dichloro-diphenyl-trichloroethane, $(Cl.C_6H_4)_2CH\text{-}CCl_3$. Paradichlorobenzene ($C_6H_4Cl_2$) is used as a moth repellent. Chlorine is an essential raw material in manufacture of many plastics, nylon and synthetic rubber.

CHLORITE, a group of green micaceous minerals which are hydrous silicates of aluminum, magnesium and ferrous iron. The name was given by A. G. Werner in 1798, from χλωρῖτις, "a green stone." Several species and many rather ill-defined varieties have been described, but they are difficult to recognize. Like the micas, the chlorites (or hydromicas) are monoclinic in crystallization and have a perfect cleavage parallel to the flat face of the scales and plates. The cleavage, however, is not quite so prominent as in the micas, and the cleavage flakes though pliable are not elastic.

The chlorites usually occur as soft (H. = 2–3), scaly aggregates of a dark-green colour. They vary in specific gravity between 2.6 and 3.0, according to the amount of iron present. Well-developed crystals are met with only in the species clinochlore and penninite; those of the former are six-sided plates and are optically biaxial, while those of the latter have the form of acute rhombohedra and are usually optically uniaxial. The species prochlorite and corundophilite also occur as more or less distinct six-sided plates. These four better-crystallized species were grouped together by G. Tschermak as orthochlorites, the finely scaly and indistinctly [illegible] is being grouped by the same author as leptochlorites.

Chemically, the chlorites are distinguished from the micas by the presence of a considerable amount of water (about 13%) and by not containing alkalies; from the soft, scaly, mineral talc they differ in containing aluminum (about 20%) as an essential

constituent. The magnesia (up to 36%) is often in part replaced by ferrous oxide (up to 30%), and the alumina to a lesser extent by ferric oxide; alumina may also be partly replaced by chromic oxide, as in the rose-red varieties kämmererite and kotschubeite.

The chlorites usually occur as alteration products of other minerals, such as pyroxene, amphibole, biotite, garnet, etc., often occurring as pseudomorphs after these, or as earthy material filling cavities in igneous rocks composed of these minerals. Many altered igneous rocks owe their green colour to the presence of secondary chlorite. Chlorite is also an important constituent of many schistose rocks and phyllites, and of chlorite-schist it is the only essential constituent. (L. J. S.)

CHLOROFORM (TRICHLOROMETHANE, $CHCl_3$) is the most potent and most rapidly acting of the volatile anaesthetics. It is a clear, colourless, noninflammable, sweet-smelling fluid with a pleasant but burning taste; molecular weight 119.5; boiling point 61° C. (142° F.), specific gravity of the fluid 1.476 and specific gravity of the vapour 4.1. It is manufactured by chlorination of alcohol or acetone in an alkaline solution. When heated in air or exposed to light it can eventually form phosgene ($COCl_2$), a poisonous gas, and it is decomposed by alkali to formate, a relatively harmless salt. Chloroform dissolves in 210 volumes of water, and it is miscible with alcohol, ether, benzene and with fixed and volatile oils.

It was prepared in 1831 simultaneously by Samuel Guthrie in the United States, J. von Liebig in Germany and E. Soubeiran in France. Sir James Young Simpson of Edinburgh first used it as an anaesthetic in 1847. Chloroform anaesthesia was used extensively, particularly in obstetrics, but fell into disrepute because of its dangers. Because of its extreme potency overdosage may easily occur, resulting in damage to the heart (depression of the myocardium, arrythmia, tachycardia, ventricular fibrillation) and to the liver (immediate or delayed degeneration). The blood pressure may fall because of decreased tone in the peripheral blood vessels. It is more often administered by dropping it upon an open mask or by blowing the vapour into the airway.

R. Waters *et al.* re-evaluated chloroform anaesthesia and showed that the toxicity of chloroform relative to the anaesthetic dose is not greater than that of most other anaesthetics, though overdose and sudden changes in concentration are more difficult to avoid because of its potency. Inadequate oxygenation and accumulation of carbon dioxide caused either by depression of the respiration or rebreathing of the same atmosphere under the mask are responsible for the majority of complications.

Correctly used there still remained indications for chloroform anaesthesia; *e.g.*, in obstetrics, in warm climates and in circumstances where there would be a danger of explosion from other anaesthetics. Where high temperature would evaporate ether too rapidly, chloroform is more useful because of its higher boiling point. A patient anaesthetized with chloroform recovers in ½ hour to 2 hours.

About 90% of the agent in the body is exhaled through the lungs while the rest is excreted in the urine and faeces.

In anaesthetic concentrations the vapour is not irritating to the respiratory tract. Liquid chloroform is used as a counter-irritant or rubefacient in a number of liniments and ointments. Chloroform water U.S.P. is frequently used as a constituent of cough medicines and sedatives and as a carminative. In instances where a higher concentration of chloroform is desired, chloroform spirit N.F. is useful (85% to 91% alcohol by volume).

(D. W. B.)

CHLOROMYCETIN (chemical name CHLORAMPHENICOL) is an antibiotic substance originally obtained from cultures of the actinomycete *Streptomyces venezuelae* and used in the treatment of many infectious diseases. It was the first of the broad-spectrum antibiotics to be reported, being characterized and identified by Paul R. Burkholder in 1947.

Chemical synthesis of the substance was reported in 1950, at which time the official name "chloramphenicol" was applied to the compound.

Chloromycetin has been found to be effective against a wide variety of infectious agents, including both gram-negative and gram-positive bacteria, certain rickettsiae, spirochaetes and viruses. It acts to inhibit the growth and multiplication of the microorganisms sensitive to it. Chloromycetin usually is given orally and is rapidly absorbed from the gastrointestinal tract, diffusing readily into the body tissues and fluids.

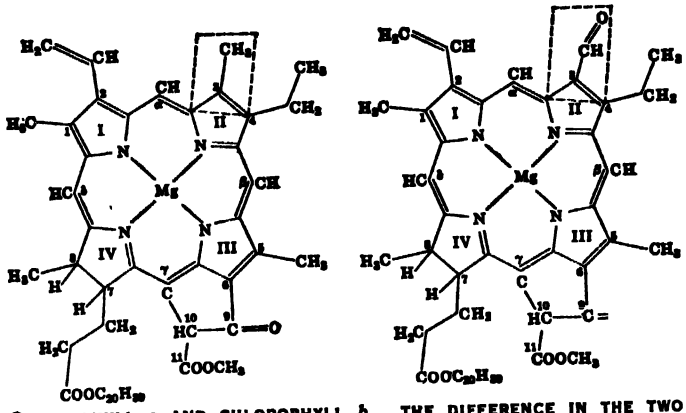
Gastrointestinal disturbances and diarrhoea are not commonly seen following the administration of chloromycetin, and, because of the rapid inactivation of the antibiotic in the digestive tract, little inhibition of the normal bacterial flora of the large bowel is observed.

In rare instances, the administration of chloromycetin has been complicated by the development of an aplastic anaemia due to depression of the bone marrow by the drug.

See H. Welch and C. N. Lewis, *Antibiotic Therapy* (Washington, 1951; London, 1952). (T. W. L.)

CHLOROPHYLL, CHEMISTRY OF. The green pigment which is present in leaves and algae is known as chlorophyll. Attempts to prepare the colouring matter of leaves in a pure form have shown that it is not homogeneous. R. Willstätter was able to separate it into four components: two green ones, chlorophylls *a* and *b* ($C_{55}H_{72}O_5N_4Mg$ and $C_{55}H_{70}O_6N_4Mg$); and two yellow ones, carotene ($C_{40}H_{56}$) and xanthophyll ($C_{40}H_{56}O_2$). At the same time, he found that the ratio of the blue-green chlorophyll *a* to the yellow-green chlorophyll *b* is 3:1, while that of xanthophyll to carotene is 2:1. The proportion of chlorophyll *a*+*b* to xanthophyll + carotene is about 3:1.

Later work (V. Lubimenko, 1921; A. Stoll and E. Wiedemann, 1938) showed that these pigments are not present in the leaf in the free state but are combined with a protein in the form of chloroplastin. Consequently, they pass into ether from an aqueous solution of the leaf pigment only after splitting the organic complex (called "symplex" by Willstätter, 1934). Chloroplastin is decomposed not only by high concentrations of salt but also by the presence of alcohol or acetone, so that the normal extraction process using these solvents liberates the individual pigments.



The separation of the carotenoids and the chlorophylls is achieved by distribution between suitable solvents, according to the method of Willstätter and Stoll (1913). Later, the technique of chromatographic analysis was employed to prepare the components in a pure state and to test their homogeneity. This led to preparations which careful spectrographic analyses proved to be of uniform composition (A. Winterstein and G. Stein, 1934; G. Mackinney, 1940–42; F. P. Zscheile, 1934–43). The pure chlorophylls are dark-green amorphous waxes; crystalline derivatives can be obtained only by degradation and elimination of the phytol. The methods employed for the identification of the chlorophylls and for their quantitative determination are based upon characteristic absorption and fluorescence spectra (C. Dhéré and O. Biermacher, 1914–36; A. Hagenbach, F. Auerbacher and E. Wiedemann, 1936; A. Stern and co-workers, 1936–38; F. P. Zscheile and D. G. Harris, 1943). In ether solution the absorption maxima correspond to the following wave lengths (A. Winterstein and G. Stein, 1933):

chlorophyll *a*:	663	623	607	577	534	507	494	432 mμ	
chlorophyll *b*:	644	614	594	567	542	503	456		

The connection between fluorescence and the part played by chlorophyll in photosynthesis has been thoroughly investigated (J. Franck, 1935–42; A. Kautsky, 1932–39; E. W. McAlister, 1937–41; E. C. Wassink, 1937–46).

The essential chemical properties of the chlorophylls and their most important derivatives will be discussed in relation to the formula depicted for chlorophyll *a*. The characteristic features of the structure of chlorophyll are the porphin system, the magnesium atom with its complex linkage, and the phytyl radical (R. Willstätter and A. Stoll, 1913).

The components of the porphin system were ascertained by Willstätter (1904–12) when he carried out his first work on the degradation of the chlorophylls. The nature of the 16-membered ring system, composed of four pyrrole rings linked by methine bridges (α-δ), was then elucidated by H. Fischer (1915–30), who confirmed the formula suggested by W. Kuester in 1912 for haemin. The stage of hydrogenation of the chlorophyll nucleus

CHLOROPHYLL *a* AND CHLOROPHYLL *b*. THE DIFFERENCE IN THE TWO STRUCTURES IS INDICATED BY THE AREAS WITHIN THE DOTTED LINES

is that of the phorbins; *i.e.*, dihydroporphyrins. The chlorophylls therefore contain two hydrogen atoms more than the porphyrins, which possess the maximum possible number of double bonds in the ring system.

The structure of the porphin system and of the individual substituents was established by H. Fischer by degradation reactions and by the syntheses of numerous porphyrins, including most of those obtained by degradation of chlorophylls.

The discovery that magnesium, bound in the form of a metallic complex, forms an essential component of the molecules of the natural chlorophylls caused great surprise at the time (R. Willstätter, 1904), and this type of magnesium linkage remained unique. It may be that the magnesium has a share in the part played by chlorophyll in the assimilation process. The magnesium atom also constitutes a characteristic difference between the chlorophylls and the blood pigment haemin, which is an iron complex but otherwise possesses a similar structure, including a porphyrin system whose substituents agree closely with those of the chlorophyll porphyrins. On treating the chlorophylls with acids, the magnesium atom is easily split off, the colour then changing from pure green to brownish green. The magnesium can be replaced by copper, zinc or other metals. The corresponding copper complexes are stable and are used as industrial pigments; *e.g.*, in the soap and cosmetic industries.

The structure of the simple unsaturated alcohol phytol, $C_{20}H_{40}O$, was elucidated by F. G. Fischer (1928) by total synthesis, which showed it to be an isoprene derivative. It was subsequently demonstrated that phytol, as a structural component of vitamins E and K_1, is connected with special physiological functions:

$$H_3C-\underset{CH_3}{\underset{|}{CH}}-(CH_2)_3-\underset{CH_3}{\underset{|}{CH}}-(CH_2)_3-\underset{CH_3}{\underset{|}{CH}}-(CH_2)_3-\underset{CH_3}{\underset{|}{C}}=CH-CH_2OH.$$

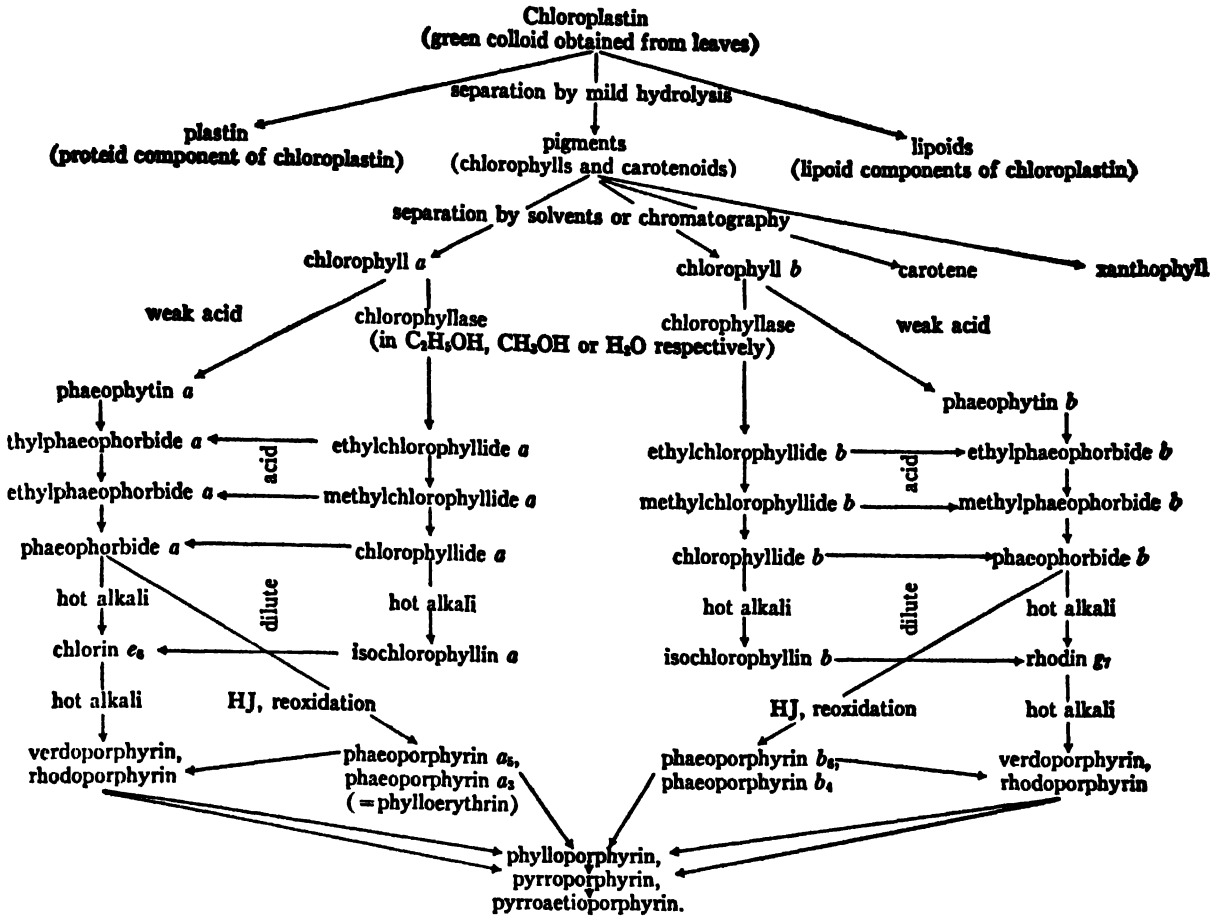
Before discussing the individual reactions by which derivatives of chlorophyll may be formed, it should be mentioned that chlorophyll *b* differs from chlorophyll *a* only in having an aldehyde group in position 3 in ring II in place of a methyl group; *i.e.*, it has an oxygen atom in place of two hydrogen atoms. Most reactions, therefore, follow the same course with both components, so that they can be discussed as one.

Among the simple reactions which leave the phorbin system intact and do not alter the relative positions of the substituents, the action of the specific enzyme, chlorophyllase, and the reactions with dilute acids and alkalies (*see* table) are worthy of mention.

In green leaves, chlorophyll is accompanied by the enzyme chlorophyllase, the quantity of which naturally varies according to the variety of plant. Its specific action is the removal of the phytyl group, which is replaced by water, methyl or ethyl alcohol according to the nature of the medium present (R. Willstätter and A. Stoll, 1910; C. Weast and G. Mackinney, 1940). In this way, chlorophyllides are produced, which still contain magnesium. The reaction is reversible, since chlorophyllase can also be used to introduce phytol (R. Willstätter and A. Stoll, 1910), as well as other higher alcohols (H. Fischer, 1938), into the chlorophyll molecule.

Dilute acids split off the magnesium from chlorophyll and chlorophyllides with the formation of phaeophytin and the corresponding phaeophorbides, respectively. This reaction is also reversible, since it is possible by means of the Grignard reagent (R. Willstätter and L. Forsén, 1911) or magnesium alcoholate (A. Stoll and E. Wiedemann, 1933; H. Fischer, 1934) to reintroduce the magnesium.

By the action of hot alkalies, both the chlorophylls and the phaeophytins and phaeophorbides are converted into tricarboxylic acids by saponification of the phytyl- and methylester groups and the cleavage of the carbocyclic side ring (C_6–C_γ). Thus, the chlorophylls yield the isochlorophyllins, which are converted by acidification into chlorin e_6 in the case of chlorophyll *a*, and into rhodin g_7 in the case of chlorophyll *b*, these end products being also obtained by the above reaction from the phaeophorbides and their esters.



The determination of the structure of the chlorophylls and their primary derivatives was carried out by way of the related porphyrins. These are obtained by degradation of the phorbins with alkali, or by treatment with hydrogen iodide. This reagent reduces only the double bonds. During the subsequent working up, aerial oxidation takes place until the ring system is completely dehydrogenated. As will be described later, at the same time a vinyl group is converted to an ethyl group during the reduction. It therefore follows that the most important phaeoporphyrins phaeoporphyrin a_5 in the *a* series and phaeoporphyrin b_6 in the *b* series, formed in this way are isomers of the phaeophorbides *a* and *b*. The numerals added as subscripts indicate the number of oxygen atoms present. Phaeoporphyrin a_5 still contains the carbocyclic side ring from C_6 to C_γ which, as an acetoacetic ester group, is responsible for the ready transformation into the tricarboxylic acids chlorin e_6 and chloroporphyrin e_6, respectively.

In order to confirm this acetoacetic ester grouping, it was essential to demonstrate the presence of an enolizable keto group, which was achieved by the preparation of oxime and benzoyl derivatives of phaeophorbide *a*. By oximation of phaeophorbide *b* it was possible to prove the presence of a further carbonyl group in addition to the keto group, so that a dioxime and two monoximes were obtained in this case (A. Stoll and E. Wiedemann, 1934).

Enolization in the carbocyclic side ring is also proved by the so-called phase test, which is characteristic of the intact chlorophyll molecule. On shaking an ethereal chlorophyll solution with concentrated alcoholic alkali, the green colour changes suddenly to brown, followed, after several minutes, by a return of the green colour owing to hydrolysis of the carbocyclic ring. Oxidized chlorophyll derivatives, which form even on standing in alcoholic solution, especially on the alkaline side, no longer give the phase test and are known as allomerized chlorophyll derivatives and purpurins (J. B. Conant, 1931–34; A. Stoll and E. Wiedemann, 1932–35; H. Fischer and co-workers, 1933).

The presence of the vinyl group in position 2 of the chlorophyll molecule was proved by hydrogenation and by a specific oxidation reaction (oxoreaction). Its position was confirmed by elimination of the acetyl group thus produced and identification of the resulting porphyrin (H. Fischer and co-workers, 1935).

The green compounds, the phorbins, to which the chlorophylls and their primary derivatives belong, arise from the red porphyrins by the reduction of one of the double bonds in the nucleus. The natural phorbins are further characterized by the above-mentioned vinyl group in place of the ethyl group in position 2. The fact that the phorbins are dihydroporphyrins was proved by oxidation of their copper complexes (H. Fischer and K. Herrle, 1937; H. Wenderoth, 1939; H. Gibian, 1942). The placing of the two hydrogen atoms in positions 7 and 8 in the pyrrole ring IV followed from the optical activity of chlorophyll derivatives in which other asymmetric centres had been eliminated (H. Fischer and H. Wenderoth, 1940). The optical rotation in acetone is $[\alpha]^{25}_{720}$ = −262° for chlorophyll *a*, and $[\alpha]^{25}_{720}$ = −267° for chlorophyll

b (A. Stoll and E. Wiedemann, 1933).

In principle, the conversion of porphyrins into green compounds can be achieved by hydrogenation. The main obstacles which have so far prevented a total synthesis of the chlorophylls are the severity of the conditions which have to be employed and the simultaneous reduction of the 2-vinyl group if previously introduced. In the case of simple porphyrins, it has been possible to effect the introduction of hydrogen in the required 7:8 position (A. Treibs and E. Wiedemann, 1928; H. Fischer and H. Helberger, 1929; H. Fischer and H. Wenderoth, 1940). The introduction of magnesium, of the phytyl and vinyl radicals and of the carbocyclic side ring has been carried out successfully.

As precursors of the chlorophylls in plants, protochlorophylls were found which are converted into chlorophylls on exposure to light (N. A. Monteverde and V. Lubimenko, 1894–1912). It is probable that these protochlorophylls belong to the porphyrins but otherwise possess the same structure as the chlorophylls (K. Noack, 1928–31; A. Seybold, 1937).

A chlorophyll derivative has been found in photosynthetic bacteria and has been named bacteriochlorophyll (C. B. van Niel, 1932–36). Its structure can be derived from that of chlorophyll *a* by the addition of two H atoms to the double bond in ring II and by replacing the vinyl group in position 2 by an acetyl group (H. Fischer and co-workers, 1937–38).

Compared with the spectra of the chlorophylls, the absorption bands of bacteriochlorophyll are shifted into the infra-red (C. B. van Niel, 1938).

Only brief reference can be made to the part played by the leaf pigments in the assimilation of carbon dioxide without discussing the many theories relating to this phenomenon. An important result is the confirmation that the assimilatory quotient of the expired oxygen to the assimilated carbon dioxide is always equal to 1 (R. Willstätter and A. Stoll, 1917). The separation of the chain of reactions into individual stages, as was possible with other natural chemical processes, had not been achieved by the 1950s. A step in this direction was indicated by the reduction of carbon dioxide by organic material in the absence of light which is observed in special cases with algae and bacteria (G. B. van Niel, 1931–46; H. Gaffron, 1940).

The function of chlorophyll in photosynthesis has been defined as that of an energy transformer or of an assimilatory ferment (R. Emerson, 1936; A. Stoll, 1936).

The part played by carbon dioxide in photosynthesis was elucidated by use of radioactive carbon (Calvin and Benson, 1947).

The combination of chlorophyll with protein in chloroplastin is of special significance for this function, since only as a result of this combination is chlorophyll able to remain resistant to light (Lubimenko, 1921). Chloroplastins from different plants are not identical. A characteristic of chloroplastin is its great tendency toward agglomeration, and even the smallest molecular weights measured by the ultracentrifuge on electrophoretically homogeneous chloroplastin preparations run into several millions (A. Stoll and E. Wiedemann, 1938–47). (A. STL.)

In the 1950s chlorophyll was exploited commercially as a deodorant. It was incorporated into a variety of products, including tooth paste and dog food.

CHLOROPICRIN, product of the distillation of bleaching powder with many nitro compounds (*e.g.*, picric acid, nitromethane), may be prepared also by the action of concentrated nitric acid on chloral or chloroform, or by the action of aqua regia (*q.v.*) upon almost any organic substance. The commonest method of preparation (A. W. von Hofmann, 1866) consists of adding a solution (saturated at 30° C.) of one part of picric acid to a paste of ten parts of bleaching powder and water. A violent reaction occurs and chloropicrin (nitrochloroform, trichloronitromethane), $NO_2.CCl_3$, distils over, generally without external heating. It is a colourless liquid of boiling point 112° C. and of specific gravity 1.692. It is almost insoluble in water but is readily soluble in alcohol; it has a sharp smell, and its vapour powerfully affects the eyes. Chloropicrin has been employed in chemical warfare (*q.v.*) as a lachrymatory, irritant and lethal agent. High concentrations of this chemical cause fatal lung in-

juries and death may ensue from exposure to its action even at low concentrations.

CHLOROPLAST, the botanical name for that structure in the plant cell which carries the green pigment, chlorophyll (*see* CHLOROPHYLL, CHEMISTRY OF; LEAF; PLANTS AND PLANT SCIENCE).

CHLOROSIS, the botanical term for loss of colour in a plant-organ, a sign of disease; also in medicine, a form of anaemia (*q.v.*).

CHMIELNICKI, BOGDAN (*c.* 1593–1657), hetman of the Cossacks, but a Pole by descent, was born near Chigirin in the Ukraine. After serving with the Cossacks in the Ukraine campaign in 1646, against the Turks, he suffered Polish persecution as a royalist and a Cossack, and he fled to the Cossack settlements on the Lower Dnieper. On April 11, 1648, at an assembly of the Zaporozhians (*see* POLAND: *History*), he declared his intention of fighting the Poles and was elected *ataman*. As a result of his victories at Zhovti Vody and Kruta Balka in May the serfs rose. Throughout the Ukraine the Polish gentry and the Jesuits were hunted down and slain. The rebels swarmed over the palatinates of Volhynia and Podolia, and Chmielnicki routed the Poles at Pilawce (Sept. 23). In June 1649 he entered Kiev, where he permitted the committal of atrocities on the Jews and Roman Catholics. His extravagant demands at the peace congress at Pereyaslavl led to the renewal of war, which was ended by the compact of Zborow. Chmielnicki was recognized as a semi-independent prince of the Ukraine. His attempt to carve a principality for his son out of Moldavia led to the third outbreak of war in 1651. At Beresteczko (July 1, 1651) Chmielnicki was defeated. In 1652 he sent an embassy to the Tsar asking for Russia's alliance, and in 1654 took an oath of allegiance to him. All hope of an independent Cossack state was thus at an end. Chmielnicki died on Aug. 7, 1657.

See P. Kulish, *On the Defection of Malo-Russia from Poland* (Rus.) (Moscow, 1890); S. M. Solovev, *History of Russia*, vol. x. (Rus.) (Moscow, 1857, etc.); R. N. Bain, *The First Romanovs*, ch. iii.–iv. (1905).

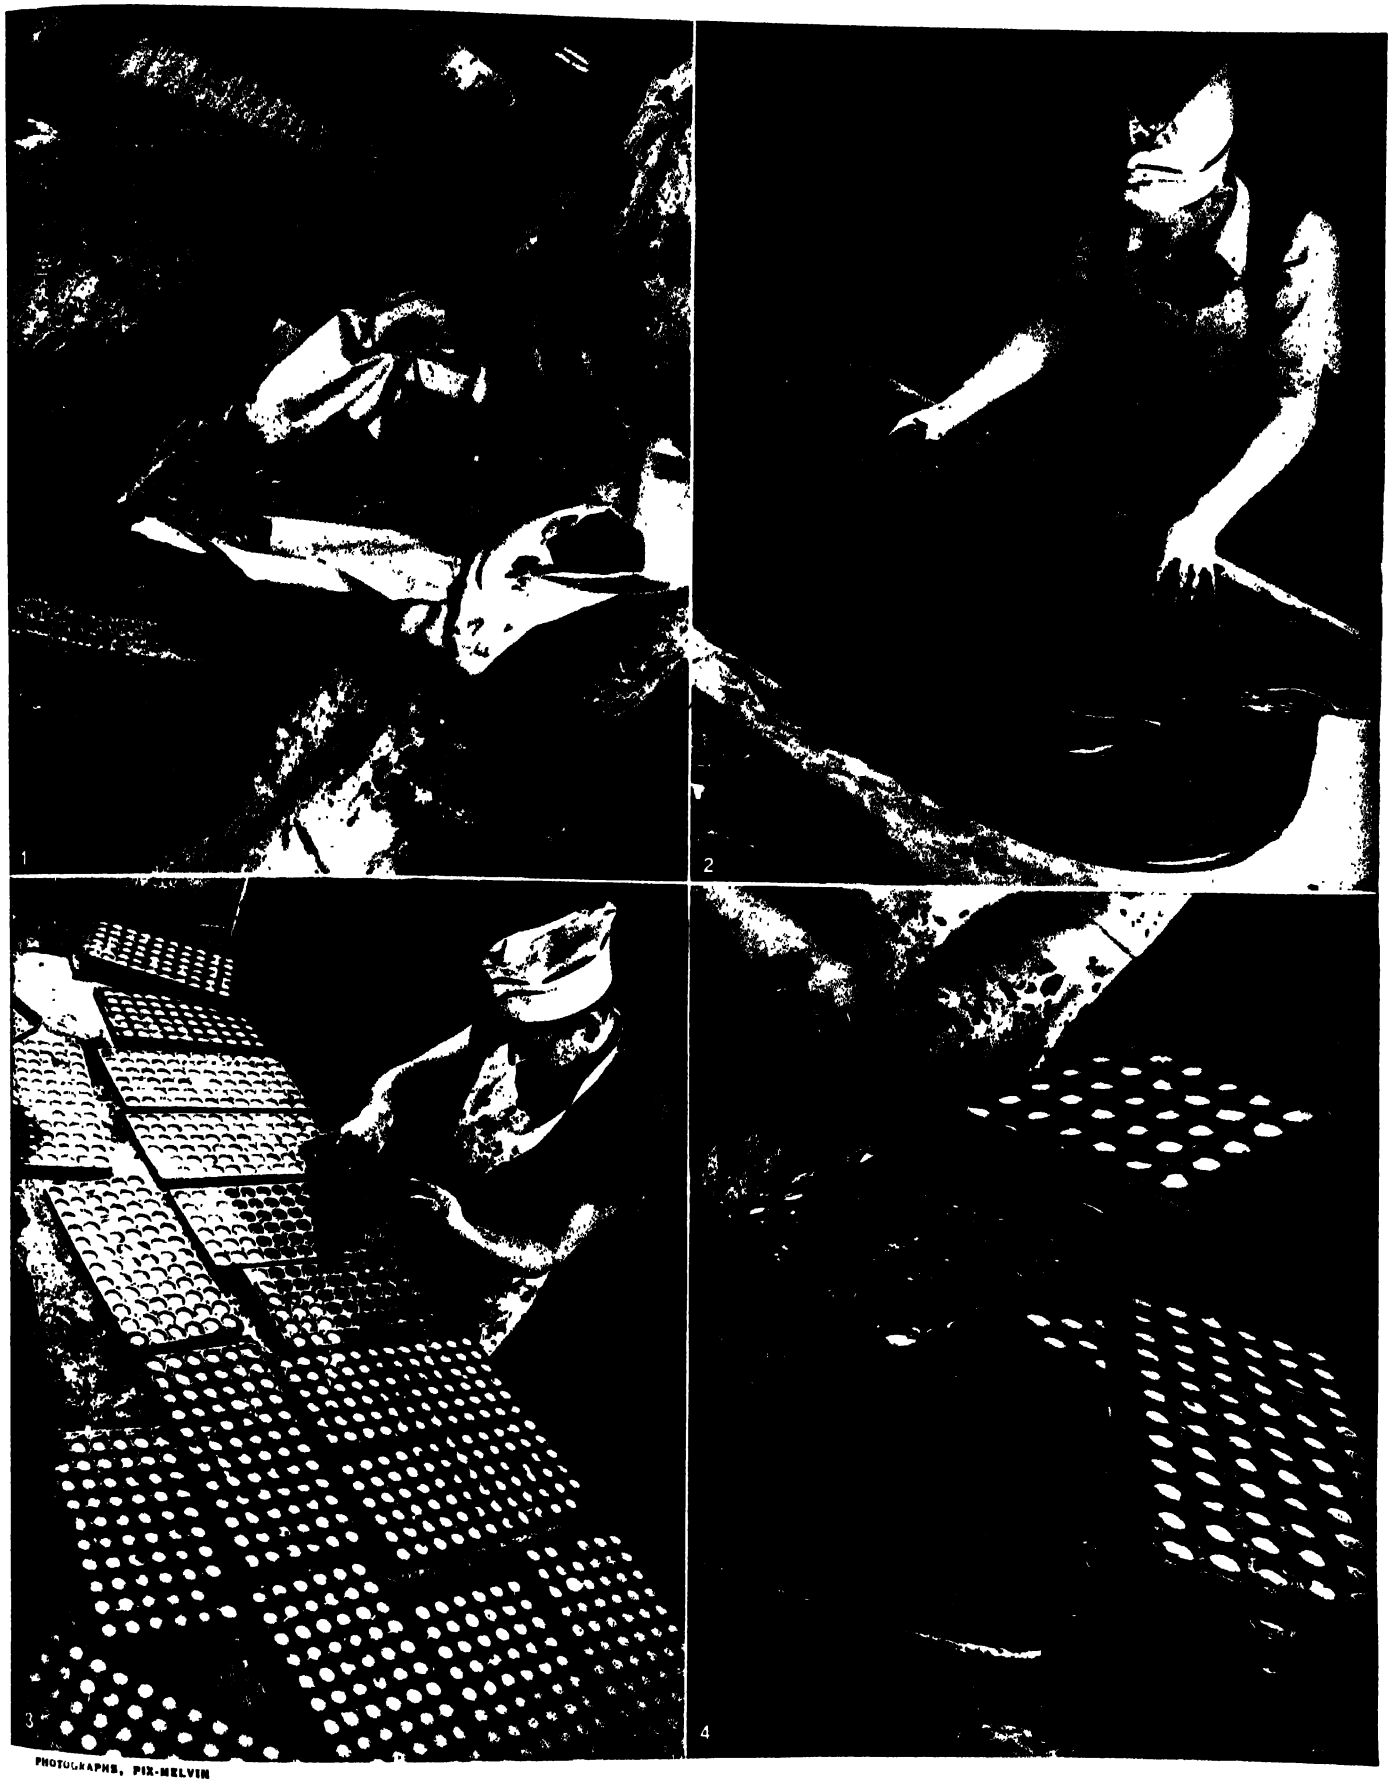
CHOATE, JOSEPH HODGES (1832–1917), U.S. lawyer and diplomat, was born at Salem, Mass., on Jan. 24, 1832. He was the son of Dr. George Choate, a physician of considerable note. He was admitted to the bar in 1855 and in 1856 began practice in New York city. Choate was associated with many of the most famous litigations in American legal history, including the Tilden, A. T. Stewart and Stanford will cases, the Kansas prohibition cases, the Chinese exclusion cases, the Maynard election returns case and the income tax suit. In 1871 he became a member of the "Committee of Seventy" in New York city, which was instrumental in breaking up the "Tweed Ring." His greatest reputation was won, perhaps, in cross-examination. In politics he allied himself with the Republican party on its organization, being a frequent speaker in presidential campaigns, beginning with that of 1856. He never held political office but he was ambassador to Great Britain from 1899 to 1905. In England he won great personal popularity, and accomplished much in fostering the good relations of the two great English-speaking powers. He was one of the representatives of the U.S. at the second peace congress at The Hague in 1907. Upon the outbreak of World War I he ardently supported the British and Allied cause and severely criticized President Wilson's hesitation to recommend America's immediate co-operation, but shortly before his death retracted his criticism. He died in New York on May 14, 1917. Among his last works were *Abraham Lincoln and Other Addresses in England* (1910) and *American Addresses* (1911).

See *The Choate Story Book* (1903); T. G. Strong, *Joseph Choate, New Englander, New Yorker, Lawyer, Ambassador* (1917); *Joseph Choate, a Great Ambassador* (1918); Edward Sandford Martin, *The Life of Joseph H. Choate* (1920); *Arguments and Addresses of Joseph Hodges Choate*, edit. Frederick C. Hicks (1926).

CHOATE, RUFUS (1799–1859), U.S. lawyer and orator, was born at Ipswich (Mass.) on Oct. 1, 1799. He graduated at Dartmouth college in 1819 and spent a year in the law school of Harvard university. He was admitted to the Massachusetts bar in 1823 and practised for five years, during which time he served in the Massachusetts house of representatives (1825–26) and in the state senate (1827). In 1830 he was elected to congress as a Whig from the Salem district, and in 1832 was re-elected. In 1841 he succeeded Daniel Webster in the U.S. Senate, where he made a series of brilliant speeches on the tariff, the Oregon boundary, in favour of the Fiscal Bank act, and in opposition to the annexation of Texas. On Webster's reelection to the senate, Choate resumed (1845) his law practice, which no amount of urging could ever persuade him to abandon for public office, save for a short term as attorney general of Massachusetts in 1853–54. He died July 13, 1859, at Halifax, Nova Scotia, while he was en route to Europe.

His *Works* (edited with a memoir by S. G. Brown) were published in 2 vol. in 1862. The *Memoir* was afterwards published separately (1870). *See* also E. G. Parker's *Reminiscences of Rufus Choate* (1860); E. P. Whipple's *Some Recollections of Rufus Choate* (1879); and the *Albany Law Review* (1877–78).

CHOBE, a large western affluent of the middle Zambezi (*q.v.*). The river was discovered by David Livingstone in 1851, and to him was known as the Chobe. It is also called the Linyante and the Kwando, the last name being that commonly used.



CHOCOAN, an independent linguistic stock of South American Indians, so called from the Chocos, who are the best known of its tribes. At the time of the first appearance of Europeans the Chocoan tribes seem to have held a large region in northwestern Colombia and southeastern Panamá. They were one of the few South American peoples who lived in pile dwellings. The Chocoan tribes were skilful canoemen, having large canoes which they used in trade. Andagoya in 1522 heard the first rumours of the Inca empire from the coastal tribes of this stock, and from a district called Biru near the mouth of the San Juan the name Peru is supposed to have been derived. The Chocoan tribes survive today in considerable numbers but are very little known. They were described at the period of the conquest as a warlike people, living mainly by hunting and fishing and on wild vegetable products. They had an abundance of gold, which they traded with the Chibchan (*q.v.*) tribes to the east. They used poisoned arrows and also the blow-gun, which was of the two-piece type. They wore little or no clothing and lived communally in large houses of thatch, set on very high piles or sometimes in trees.

See P. Simon, *Noticias historiales de las Conquistas de Tierra Firme en las Indias Occidentales* (Bogota, 1882); W. Lehmann, *Zentral Amerika* (Berlin, 1920).

CHOCOLATE, a preparation of the cacao bean and sugar, usually flavoured, and either used as a food or mixed with hot water and milk as a drink. It is also widely used to flavour other types of food such as ice cream, bakery products and candy. Cocoa and chocolate for eating are comparatively modern preparations, whereas drinking chocolate, of a sort, has been known to Europeans since the discovery of America. The original of the modern chocolate was *chocolatl*, a frothy beverage taken cold and held in high esteem in Mexico by the Aztecs. As *chocolatl* apparently consisted simply of the roasted and ground cacao bean flavoured with peppers and other spices, it was both bitter and pungent. The Spaniards greatly improved it by adding sugar and guarded the secret of its preparation for nearly a century, when it became known in Italy, Germany and France. In 1657 a Frenchman opened a shop in London, at which solid chocolate for making the beverage could be purchased at 10*s.* to 15*s.* a pound. At this price, only the wealthy could afford to drink it; hence the appearance in London, Amsterdam and other European capitals of the fashionable chocolate houses, some of which developed later into famous clubs. About 1700 the English improved chocolate by the addition of milk. The reduction of the cost of the beverage was hampered in Great Britain by the imposition of high import duties on the raw cacao bean, and it was not until 1853, when Gladstone lowered the duty to a uniform rate of 1*d.* a lb., that chocolate became popular.

Cakes of chocolate are still the accepted material in France from which to prepare a cacao beverage, but elsewhere cocoa powder has for many years been more generally used. While the use of chocolate for drinking has declined, the amount of chocolate eaten has greatly increased.

Method of Manufacture.—In the manufacture of chocolate, cocoa beans are first cleaned to remove stones, dirt and other foreign matter and then roasted. The roasting process develops

PHOTOGRAPHS, PIX-MELVIN

MANUFACTURE OF CHOCOLATE CANDY

1. Placing solid blocks of chocolate into a melter, where they are heated to liquid form
2. After melting, the chocolate is poured onto a marble slab for cooling and working
3. Making chocolate-covered creams. The cream fillings are first poured into moulds
4. The entire tray of moulds filled with the cream centres is covered with liquid chocolate, then allowed to harden

CHOCOLATE

PHOTOGRAPHS, PIX-MELVIN

MAKING VARIOUS KINDS OF CANDIES

1. Revolving pans in which nut fillings of candies are covered with an equal distribution of chocolate
2. Workman inspecting finished chocolate-covered almonds in a revolving pan
3. Hand-dipping centres in liquid chocolate
4. Wrapping pieces of candy in tin foil
5. Packing candy in boxes

flavour, colour and serves to loosen the kernel or nib from the shell. Beans are then cracked and the shell is removed by a winnowing process. The nibs are generally ground through stone mills. During the grinding the heat of friction melts the cocoa butter present, and the resulting product comes from the mills in liquid form. It is known in the trade as "chocolate liquor." This liquor can then be cooled and moulded into cakes for use in other branches of the food industry or can be given further processing to prepare sweet chocolate, milk chocolate or cocoa powder. The U.S. standard for chocolate liquor calls for a minimum of 50% fat and a maximum of 8% ash, and 7% crude fibre on a fat and moisture-free basis. The ash and fibre limits are intended to prevent adulteration with shells.

In the manufacture of sweet chocolate, granulated or pulverized sugar is mixed with the chocolate liquor and the resulting paste is ground by passing it over steel roll refiners. As the addition of sugar reduces the over-all fat content, additional cocoa butter must be supplied to the mix to maintain sufficient fat to permit further processing and moulding. A typical sweet chocolate contains 42% chocolate liquor, 42% sugar and 16% added cocoa butter. The finer qualities of sweet chocolate are further processed to improve and develop their flavour in machines known as "Conges." This processing may take up to 96 hours. After the processing, the sweet chocolate is cooled and moulded into cakes for use by the candy industry as a coating for centres or it may be cast directly into small bars suitable for eating.

Milk chocolate is sweet chocolate in which the flavour has been modified by the addition of whole milk solids. The U.S. standard calls for a minimum of 12% whole milk solids, but most good quality chocolates may contain as much as 20 to 22% whole milk solids.

The cocoa butter required for the manufacture of sweet chocolate is obtained by pressing chocolate liquor.

Sweet chocolate in block form is recognized as a compact and valuable foodstuff. Blocks or bars are sold plain and in combination with nuts and fruits. During World War II, the high food value of chocolate was recognized through its use by the armies as an emergency ration, and at sea as a lifeboat ration. It is unique among foods because of its high calorific value combined with small bulk.

Because of shipping shortages in World War II, it was rationed in Great Britain and the United States. The method employed in the U.S. was to limit the quantity which manufacturers could grind to a fraction of the amount which the same manufacturer had ground in 1941. This fraction was changed from time to time as was found necessary to maintain a reserve stock of cocoa beans in the U.S.

Chocolates or Chocolate-covered Confectionery.—Chocolate is used for covering all manner of confections. It is prepared by the methods outlined above, but more cocoa butter is added to make it flow readily. The best work is done by hand: the vanilla crême, caramel or other confection is laid on a fork and dipped beneath the molten chocolate and then turned on to a sheet of paper. A mechanical coverer or "enrober" invented in 1903 is much used; in this machine the crêmes move on a woven wire band through a cascade of liquid chocolate.

Production of Chocolate and Cocoa Trades.—According to the United States biennial census of manufactures of 1940 the total values of products of manufactures of chocolate and cocoa was $99,018,203. Of this amount, $39,516,767 represented the value of 216,811,762 lb. of chocolate (not including chocolate coatings); $32,194,541 the value of 339,530,664 lb. of chocolate coatings; $13,199,965 the value of 153,440,919 lb. of powdered cocoa; $6,880,433 the value of 57,205,043 lb. of cocoa butter; and $1,159,041 the value of other products, chiefly chocolate and cocoa specialties. In the 39 reporting establishments there were 6,464 wage earners, who received $7,711,129 in wages. During the calendar year ending Dec. 31, 1939, the United States imported 545,010,374 lb. of raw cocoa, valued at $28,547,394; of prepared cocoa (not including confectionery), 3,587,000 lb., valued at $432,000. The United Kingdom imported 147,298 tons of raw cocoa valued at $16,076,714 in 1938, of which 78,130 tons were retained for home consumption. For the general facts of the industry, see COCOA; CONFECTIONERY MANUFACTURE.

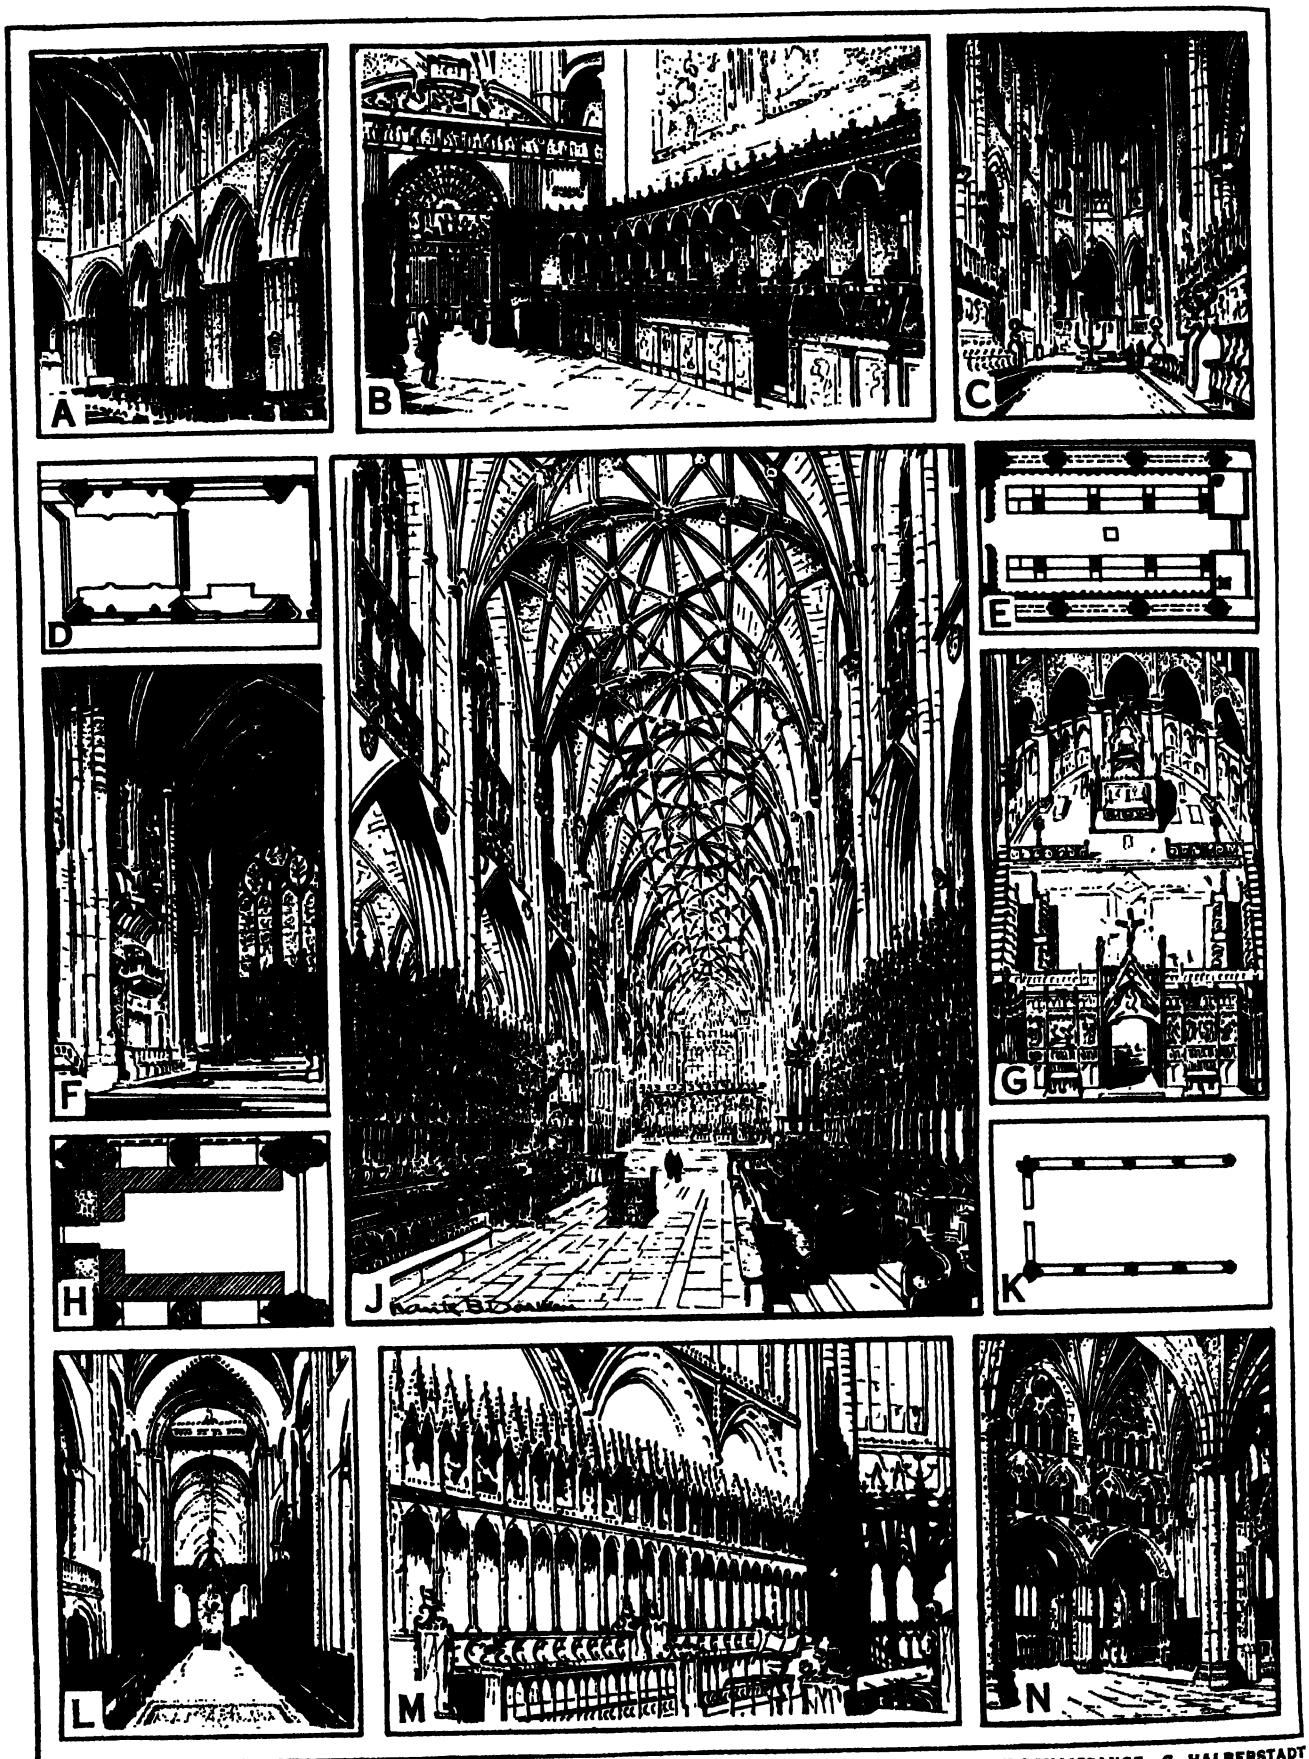
(A. W. KN.; X.)

CHOCTAW, a prominent tribe in southern Mississippi, of Muskogi stock (*see* MUSKOGIAN INDIANS). Their name is apparently a corruption of the Spanish *chato,* flattened, which referred to their practice of flattening the heads of male infants. They farmed intensively. The Choctaws were allies of the French, enemies of the British and of most of the Muskogians. In the later 18th century they began drifting west of the Mississippi, and about 1832 the majority moved to what is now eastern Oklahoma, where they remained self-governing and semi-civilized until their absorption into American citizenship in 1906. They number about 17,500 exclusive of Negro freedmen included in the "nation," but include many of mixed blood; the original population seems to have been only slightly larger.

CHODKIEWICZ, JAN KAROL (1560–1621), Polish general. In 1599 he was appointed *starosta* of Samogitia, and in 1600 acting commander-in-chief of Lithuania. In the war against Sweden for the possession of Livonia he repulsed the duke of Sudermania, afterwards Charles IX, from Riga, and in 1604 captured Dorpat. At Kirkholm (Aug. 27, 1605) he annihilated a large Swedish army; but he was hampered always by the Polish diet which denied him adequate supplies, and after helping to defeat the rebels in Poland and to relieve Riga when the Swedes again invaded Livonia, he was sent against Moscow with an army which mutinied for lack of pay and was compelled to retreat to Smolensk. On being reinforced by Prince Wladislaus, however, he took the fortress of Drohobu in 1617, and on the conclusion of the Muscovite war by the treaty of Deulina he was sent to defend the southern frontier against the Turks. He died on Sept. 24, 1621, after forcing the Ottoman army to raise the siege of Khotin.

See Adam Stanislaw Naruszewicz, *Life of J. K. Chodkiewicz* (Pol.) 4th ed. (Cracow, 1857–58); Lukasz Golebiowski, *The Moral Side of J. K. Chodkiewicz as indicated by his Letters* (Pol.) (Warsaw, 1854).



CHODOWIECKI, DANIEL NICOLAS (1726–1801), German genre painter and engraver of Polish descent, was born at Danzig on Oct. 13, 1726, and died at Berlin on Feb. 7, 1801. He began engraving in 1758. After designing and engraving several subjects from the story of the Seven Years' War, Chodowiecki produced the famous "History of the Life of Jesus Christ," a set of admirably painted miniatures, which made him popular at once. Few books were published in Prussia for some years without plate or vignette by Chodowiecki. The catalogue of his works (Berlin, 1814) includes over 3,000 items, the most famous being the picture of "Jean Calas and his Family." He became director of the Berlin Academy in 1797. The title of the German Hogarth was disclaimed by Chodowiecki himself. He actually had only one point in common with Hogarth—the practice of representing actual life and manners.

See Von Oettingen, *Daniel Chodowiecki* (1895).

CHOERILUS. (1) An Athenian tragic poet, who exhibited plays as early as 524 B.C. He was said to have competed with Aeschylus. Pratinas, and even Sophocles. According to F. G. Welcker, however, the rival of Sophocles was a son of Choerilus, who bore the same name. Suidas states that Choerilus wrote 150 tragedies and gained the prize 13 times. His works are all lost; only Pausanias (i, 14) mentions a play by him entitled *Alope.* Choerilus was also said to have introduced considerable improvements in theatrical masks and costumes.

See A. Nauck, *Tragicorum Graecorum Fragmenta* (1889); F. G. Welcker, *Die griechischen Tragödien,* pp. 18, 892.

(2) An epic poet of Samos who flourished at the end of the 5th century B.C. After the fall of Athens he settled at the court of Archelaus, king of Macedonia, where he was the associate of Agathon, Melanippides and Plato, the comic poet. The only work that can with certainty be attributed to him is the Περσηΐς or Περσικά, a history of the struggle of the Greeks against Persia. The treatment of contemporary events was a new departure in epic; he apologizes in the introductory verses (preserved in the scholiast on Aristotle, *Rhetoric,* iii, 14). The *Perseis* was at first successful, but later critics reversed this favourable judgment. Aristotle (*Topica,* viii, 1) calls Choerilus's comparisons farfetched and obscure, and the Alexandrians displaced him by Anti-

G. Kinkel, *Epicorum Graecorum Frag.* i. (1877); for another view of his relations with Herodotus *see* Müder in *Klio* (1907), 29–44.

(3) An epic poet of Iasus in Caria, who lived in the 4th century B.C. He accompanied Alexander the Great on his campaigns as court-poet. He is well known from the passages in Horace (*Epistles*, ii. 1, 232; *Ars Poëtica*, 357), according to which he received a piece of gold for every good verse he wrote in honour of the deeds of his master.

See G. Kinkel, *Epicorum Graecorum Fragmenta*, i. (1877); A. F. Näke, *De Choerili Samii Aetate Vita et Poësi aliisque Choerilis* (1817), where the above poets are carefully distinguished; and the articles in Pauly-Wissowa's *Realencyklopädie*, iii. 2 (1899).

CHOEROBOSCUS, GEORGIUS, also called CHARTOPHYLAX (*c.* A.D. 60), deacon and professor at the oecumenical school at Constantinople. A course of his lectures on grammar has come down to us in the shape of notes taken by his pupils. He drew from the best authorities—Apollonius Dyscolus, Herodian, Orion, Theodosius of Alexandria. These lectures were much used by Constantine Lascaris in his Greek grammar and by Urban of Belluno (end of 15th century). Other works: commentary on the canons of Theodosius on declension and conjugation, which is extant; a treatise on orthography, of which a fragment (on quantity) has been preserved; a tract on prosody; commentaries on Hephaestion and Dionysius Thrax; and grammatical notes on the Psalms.

BIBLIOGRAPHY.—*See* A. Hilgard, *Grammatici Graeci*, iv. (1889–94), containing the text of the commentary on Theodosius and a full account of the life and writings of Choeroboscus; L. Kohn in Pauly-Wissowa's *Realencyklopädie*, iii. 2 (1889); C. Krumbacher, *Geschichte der byzantinischen Literatur* (1897); Reitzenstein, *Etymologika*, 190, n. 4.

CHOIR, the body of singers who perform the musical portion of the service in a church, or the place set apart for them (O.F. *cuer* from Lat. *chorus*, Fr. *chocur*). Any organized body of singers performing full part choral works or oratorios is also called a choir. The word was originally applied to all the clergy taking part in services of the church.

In English cathedrals the choir is composed of men (vicars-choral or lay clerks) and boys (choristers). They are divided into two sets, sitting on the north and south side of the chancel respectively, called *cantoris* and *decani* from being on the same side as the *cantor* (precentor) or the *decanus* (dean). Surpliced choirs of women have occasionally been introduced, notably in the United States and the British colonies, but the practice has no warrant of traditional usage. (*See* VESTMENTS.) In England at the Reformation the choir services (Mattins, Evensong) replaced the Mass as the principal popular services, and, in general, only the choir vestments were retained in use. In the English cathedrals the members of the choir often retain privileges reminiscent of an earlier definite ecclesiastical status.

In architecture, (1) any part of a church intended for choir use, and (2), more commonly, the eastern end of a church, almost synonymous with chancel (*q.v.*). In developed churches of the middle ages, the choir is just to the west of the altar rail, usually between that and the crossing, although in some churches of England and Spain the space extends well into the nave (*q.v.*). In some modern churches members of the choir are placed in a western gallery; in Non-conformist churches they are frequently placed over and behind the pulpit. The choir stalls of Gothic churches such as Amiens, Exeter, Lincoln are works of great richness. In the illustration, Figure A. is from Gardner, *A Guide to English Gothic Architecture*, permission of the Cambridge University Press; C. and N. are by permission from Sir Banister Fletcher, *History of Architecture on the Comparative Method*, 8th ed. 1928 (Batsford); F. from Atkinson and Bagenal, *Theory and Elements of Architecture*, permission of Benn & Co.; L. from Greenwell, *Durham Cathedral*, permission of Andrews & Co. CHOISEUL, CÉSAR, DUC DE (1598–1675), French marshal and diplomatist, known for the best part of his life as the marshal du Plessis-Praslin, came of the old French family of Choiseul, which arose in the valley of the Upper Marne in the 10th century. Entering the army he took part in the siege of La Rochelle, assisted to defend the island of Ré against the duke of Buckingham, and accompanied the French forces to Italy in 1629. In 1630 he was appointed ambassador at the court of the duke of Savoy, and was engaged in diplomatic and administrative work in Italy till 1635, when war was declared between France and Spain. Plessis-Praslin distinguished himself in the Italian campaign which followed, and after further service in Italy he was made a marshal of France (1645). During the first War of the Fronde he assisted Condé in the brief siege of Paris; and in the second war, remaining loyal to the queen-regent and the court party, he defeated Turenne and the allied Spaniards and rebels at Rethel (or Blanc-Champ) in 1650. He became minister of state in 1652, and in November 1665 was created duc de Choiseul. He was concerned in some of the negotiations between Louis and Charles II. of England which led to the Treaty of Dover, and died in Paris on Dec. 23, 1675.

CHOISEUL, ÉTIENNE FRANÇOIS, DUC DE (1719–1785), French statesman, was the eldest son of François Joseph de Choiseul, marquis de Stainville (1700–1770), and bore in early life the title of comte de Stainville. Born on June 28, 1719, he entered the army, and during the War of the Austrian Succession served in Bohemia in 1741 and in Italy, where he distinguished himself at the battle of Coni, in 1744. From 1745 until 1748 he was with the army in the Low Countries, being present at the sieges of Mons, Charleroi, and Maestricht. He acquired a large fortune by his marriage in 1750 with a daughter of the marquis de Châtel.

Choiseul gained the favour of Madame de Pompadour, and was given the appointment of ambassador to Rome in 1753, where he was entrusted with the negotiations concerning the disturbances called forth by the bull *Unigenitus*. In 1757 his patroness obtained his transfer to Vienna, where he was instructed to cement the new alliance between France and Austria. He then replaced Antoine Louis Rouillé (1689–1761) as minister for foreign affairs, and therefore had the direction of French foreign policy during the Seven Years' War. At this time he was made a peer of France and created duc de Choiseul. Although from 1761 until 1766 his cousin César, duc de Choiseul-Praslin, was minister for foreign affairs, yet Choiseul continued to control the policy of France until 1770, and during this period held most of the other important offices of state. As the author of the "Family Compact" he sought to retrieve by an alliance with the Bourbon house of Spain the disastrous results of the alliance with Austria, but his action came too late. He reformed both the army and navy, and although too late to prevent the loss of Canada and India, he developed French colonies in the Antilles and San Domingo, and added Corsica and Lorraine to the crown of France. His management of home affairs in general satisfied the *philosophes*. He allowed the publication of the *Encyclopédie* and procured the banishment of the Jesuits and the temporary abolition of the order by Pope Clement XIV.

Choiseul's fall was caused by his action towards the Jesuits, and by his support of their opponent La Chalotais, and of the provincial parlements. After the death of Madame de Pompadour in 1764, his enemies, led by Madame du Barry and the chancellor Maupeou, were too strong for him, and in 1770 he was ordered to retire to his estate at Chanteloupe. Greatly to his disappointment Louis XVI. did not restore him to his former position, although the king recalled him to Paris in 1774, where he died on May 8, 1785.

CHOISY, FRANÇOIS TIMOLEON, ABBÉ DE (1644–1724), French author, was born in Paris on Aug. 16, 1644, and died in Paris on Oct. 2, 1724. His father was attached to the household of the duke of Orleans, and the lad became famous in court circles for his extravagance, his adoption of female dress and his numberless intrigues. He had been made an abbé in his childhood,

and poverty drove him to live on his benefice at Sainte-Seine in Burgundy, where he found a kindred spirit in Bussy-Rabutin. He visited Rome in the suite of the cardinal de Bouillon in 1676, and shortly afterwards a serious illness brought about a sudden conversion. In 1685 he accompanied the chevalier de Chaumont on a mission to Siam. He was ordained priest, and received various ecclesiastical preferments. He wrote voluminous historical works, but is remembered by his gossiping *Mémoires* (1737), which contain remarkably exact portraits of his contemporaries, although he has otherwise small pretensions to historical accuracy.

The *Mémoires* passed through many editions, and were edited in 1888 by M. de Lescure. Some admirable letters of Choisy are included in the correspondence of Bussy-Rabutin. Choisy is said to have burnt some of his indiscreet revelations, but left a considerable quantity of unpublished ms. Part of this material, giving an account of his adventures as a woman, was surreptitiously used in an anonymous *Histoire de madame la comtesse de Barres* (Antwerp, 1735), and again with much editing in the *Vie de M. l'abbé de Choisy* (Lausanne and Geneva, 1742), ascribed by Paul Lacroix to Lenglet Dufresnoy; the text was finally edited (1870) by Lacroix as *Aventures de l'abbé de Choisy*. *See* also Sainte-Beuve, *Causeries du lundi*, vol. iii.

CHOKE BORE, the bore of a gun narrowed at the muzzle to concentrate the shot.

CHOKE-DAMP, also known as "black-damp" and "stythe," is a mixture of carbon dioxide and nitrogen, pure choke-damp according to Dr. J. Haldane, containing about 13% of the former and 87% of the latter; but probably the relative proportions are variable. Choke-damp, which in this connection is more frequently known as "stythe," is found in old, abandoned, or worked portions of the mines—especially wet mines—where the ventilation is stagnant, and on the occasion of a fall in the atmospheric pressure emerges from the "wastes" ("goaves") and makes its appearance in the workings, and, being heavier than air, lies along the floor of the mine gradually ascending as it increases in volume.

Choke-damp is the result of the absorption of the oxygen in the air by the coal substance in the mine and the formation of carbon dioxide in the process; it is also produced by the decay of timber, the breathing of men and animals, the burning of lamps and candles, and the firing of explosives. Spontaneous combustion, or self-heating of coal, which is a characteristic of some coal mines, is merely the rapid absorption of oxygen by the coal, which produces carbon dioxide and carbon monoxide in the process.

Carbon monoxide is known to miners as "white-damp" but is present only in minute quantities in the mine. It is the result of incomplete combustion, may be caused by the exploding of gunpowder and other explosives, and is always present in the "after-damp" resulting from an explosion of fire-damp or of coal dust.

Whereas carbon dioxide, if present in sufficient quantity, extinguishes light and life mainly by suffocation, carbon monoxide, if present in the air to an extent greater than 1%, can be detected by a cap on the ordinary flame of a safety lamp. It is a virulent poison, its destructive effect being due to its action on the haemoglobin of the blood with which it chemically combines, robbing the body of its oxygen. But haemoglobin when saturated with carbon-monoxide cannot take up oxygen. An atmosphere containing as low as 0·2% of the dangerous gas will cause in time complete helplessness and loss of consciousness. An analysis of after-damp made by Dr. Bedson after the Usworth explosion (County Durham) in 1885 showed it to contain—

	%
Carbon dioxide (CO_2)	4·54
Carbon monoxide (CO)	2·48
Methane (CH_4 the chief constituent of fire-damp)	8·68
Oxygen	7·23
Nitrogen	76·80

Analyses of after-damp by Mr. W. I. Orsman in 1892 showed it to be composed of—

	%
Oxygen	3·9
Nitrogen	75·9
Carbon dioxide	12·1
Carbon monoxide	8·1

The bodies of persons killed by after-damp in which carbon monoxide was the fatal agent, present a pink and healthy look due entirely to its coloration effect, and *rigor mortis* is not present. (R. R.)

CHOKING, the obstruction of a passage. In animals choking is the interference with breathing caused by obstruction or compression of the larynx, windpipe or other respiratory passages and may lead to suffocation (*see* TRACHEOTOMY). In electricity, a *choking coil* is designed so that it will pass alternating currents of low but not of high frequencies (*see* RADIO RECEIVER).

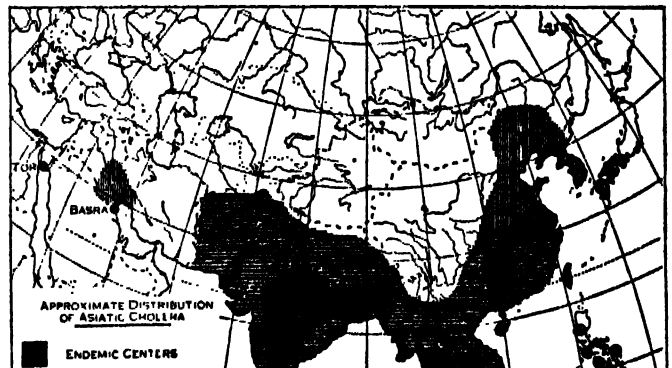
In internal combustion engines (*q.v.*) a *choke tube* is a constriction in a pipe, which increases the velocity of the fluid in its neighbourhood and thus reduces the pressure (*see* HYDROMECHANICS: *Hydrodynamics*); this results in the liquid from the carburettor being sucked into the tube.

CHOLAS, a Hindu dynasty which became the paramount power in southern India toward the end of the 10th century A.D. From the 3rd century to the 9th Chola history is obscure. The *Purananuru*, one of the eight major anthologies of the early Tamil classics, contains the names of a number of Chola kings of whom Karikala was the most famous; but in the absence of inscriptions their chronology is merely conjectural. There is apparently no truth in the legend that Karikala invaded Ceylon and transported thousands of its inhabitants to work as slaves on the banks of the Cauvery. The first ruler for whom there is definite historical evidence is Vijayalaya (*c.* 836–870). Under his son Aditya I (*c.* 870–907) the Pallavas were defeated and the Chola dominions extended until they bordered on those of the Rashtrakutas of the Deccan. The reign of his son Parantaka I (907–953) saw a further extension of their power from the Velur river to Cape Comorin, but toward the end of his days the Chola kingdom was overrun by the Rashtrakutas under Krishna III. With the accession of Rajaraja the Great, in 985, the Cholas regained their lost possessions and became the paramount power in southern India. Rajaraja's conquests included the Chera and Pandya country, Vengi and Kalinga. With the aid of a powerful fleet he annexed the Maldive Islands and conquered Ceylon, destroying its ancient capital of Anuradhapura. He was a great builder of stone temples to which the magnificent Siva temple at Tanjore still bears witness. The Chola empire reached its greatest extent in the reign of his son Rajendra I (1012–44). It is usually supposed that he reached the Ganges during one of his expeditions, but the evidence of the Tiruvalangadu plates proves that the expedition was undertaken by one of his generals and that Rajendra himself never advanced beyond the Godavari. To celebrate this achievement he assumed the title of Gangaikonda and built a new capital city, Gangaikondacholapuram, to the northeast of Tanjore. Modern scholarship inclines to the belief that he undertook a naval expedition against the Sailendra empire of Srivijaya and its dependencies in the Malay peninsula and archipelago, but there is no evidence that any territory was annexed to the Chola empire. (For the identification of Kadaram with the kingdom of Palembang in Sumatra *see* G. Coedès, "Le Royaume de Crivijaya," *Bulletin de l'École Française d'Extrême-Orient*, vol. xviii [Paris, 1918]). His son Rajadhiraja had to wage continual wars against neighbouring princes who were anxious to wipe out the humiliation they had suffered at the hands of the Cholas; he was killed in 1052 at the battle of Koppam on the banks of the Tungabhadra. In 1070 the direct Chola line appears to have become extinct and under Kulottunga I (1070–1120) the eastern Chalukya and Chola kingdoms were united. The empire now began to disintegrate; Ceylon recovered its independence and Gangavadi was lost to the rising power of the Hoysalas of Mysore. By the year 1267 the Chola empire had ceased to exist, and it was not until the end of the 14th century that its place was taken by the mighty Hindu empire of Vijayanagar.

Chola administration was well organized, especially in the sphere of local government.

There were two types of village assemblies, a general assembly of the whole village known as the *ur*, and the *sabha* which was composed entirely of Brahmans.

See K. A. N. Sastri, *The Colas*, 3 vol. (Madras, 1935–37); L. de la Vallée Poussin, *Dynasties et histoire de l'Inde depuis Kanishka jusqu'aux invasions musulmanes* (Paris, 1935). (C. C. D.)



CHOLERA is a term that has been applied to a wide variety of acute diarrhoeal diseases of short duration. Cholera nostra, simple cholera, European cholera, British cholera and cholera infantum or summer diarrhoea of infants are relatively mild enteric diseases characterized by sudden onset, acute diarrhoea sometimes accompanied by vomiting, low fatality and recovery in one to five days. These diseases are of diverse, and in many instances uncertain, actiology. Known aetiologic agents include the paratyphoid bacilli (*Salmonella*), certain of the dysentery bacilli, especially the Sonne and Newcastle types, and some members of the genus *Proteus*. It is probable that certain of the lesser known enteric bacilli, such as the paracolon bacilli, are causally associated with this kind of disease in man. In many instances these infectious agents are transmitted by food, and differentiation of food-borne infections and food poisoning is not sharp; it is not unlikely that in the past food poisoning such as that produced by ingestion of staphylococcal enterotoxin was classed as simple cholera. These diseases are, however, to be distinguished from the acute, specific and highly fatal infection with *Vibrio cholerae* known as true cholera, Indian cholera or, most commonly, Asiatic cholera. In modern medical literature the generic use of the term cholera fell into disrepute, and came to refer almost invariably to Asiatic cholera. These enteric diseases of man are unrelated to fowl cholera, an epidemic haemorrhagic septicaemia of chickens caused by the bacillus *Pasteurella aviseptica*, or to hog cholera which is of virus actiology; man is not susceptible to infection with either of these agents.

Historical.—References to acute, epidemic diarrhoeal disease are not uncommon in historical literature. As early as the 5th century B.C. Thucydides described the occurrence of such a disease in Athens, and the earliest report in the Indian literature of what may have been cholera is that of Susrata in the 7th century. A.D. The χολερα of Hippocratic writings does not refer to diarrhoeal disease. The earlier descriptions are equally applicable to bacillary dysentery, and it was not until the 15th century that acute epidemic diarrhoeal disease which was probably cholera was described; such, for example, was the epidemic disease that brought about the destruction of Ahmed Shad's army in 1438, and that described by Jacobus Bontius in the Netherlands Indies in 1629. According to the Chinese writers, cholera reached China from India in 1669.

Cholera, however, was probably endemic in India, in the delta of the Ganges river and in lower Bengal, in remotest antiquity. With increasing facilities for travel, the disease spread from India overland through Persia into Russia, and by sea routes to China and the far east on the one hand, and on the other through Arabia into Asia Minor and Egypt and thence into Europe proper. Later it became apparent that there was also an endemic focus of infection in central China, in the valley of the Yuan river which flows into the Yangtze river through Tung Ting lake, and from which the disease spread down the valley of the Yangtze and into the coastal areas. Whether this endemic centre was a recent development or only recently discovered is problematical, but it was not associated with the great pandemics of the 19th century and early part of the 20th century.

The first of the great pandemics began in India in 1817, and spread by land to China in 1818, to Ceylon in 1819 and by sea to Mauritius and East Africa in 1820, to the Philippines, China and Japan in 1822 and by land to Persia and Arabia in the same year and thence to Russia through Astrakhan in 1823, but this pandemic did not reach Europe proper. Another pandemic wave began in India in 1826 and followed a similar course, but spread farther, reaching European Russia, via China, Manchuria and Mongolia, and through Astrakhan. It reached Moscow in 1830 and spread from Moscow to St. Petersburg, into Germany and across the North sea to Great Britain, reaching Edinburgh in 1832. The infection was carried from Europe to North America, entering Canada in 1832 and spreading south to Fort Dearborn (Chicago) and down the Mississippi valley. It appeared concurrently in New York city and Boston and spread south and west, so that by 1836 cholera was present in most of the U.S. and did not disappear until 1838. The pandemic wave occurring between 1840 and 1849 and that of 1863–66 reached Europe by overland routes via Mecca and Egypt and spread to North America, giving rise to the outbreaks of 1867 and 1873. Another pandemic began in India in 1879 and the disease reached Europe through Egypt by 1883, affecting especially the Mediterranean ports of France, Spain and Italy. It was during this epidemic that Robert Koch carried out his studies on the aetiology of the disease (*see* below). Another serious outbreak spread from India in 1891 and was carried to Europe by pilgrims returning from Mecca, reaching that continent the following year and primarily affecting European Russia. It was in this outbreak that the Russian composer Peter Ilich Tschaikovsky died of cholera. Still another great pandemic began in 1902, spreading from India to China and the Philippines, and to Europe by 1908 and 1910. With the development of knowledge of the aetiology of the disease and efficacious methods of control, no pandemic spread occurred after 1910. Cholera recurs annually in India in epidemic form and with great loss of life, usually not less than 200,000 deaths per year. The disease has spread into eastern Europe on occasion, as during the Balkan War in 1913; there were a few cases in central Europe during World War I, and several small outbreaks in Russia and Poland in the 1920s; an epidemic also occurred in Egypt during the late summer and early autumn of 1947. Epidemic cholera occurs with some frequency in the far east, especially in Burma, Indochina, the China coast and Manchuria, and sporadic cases occur in the Philippines and Indonesia. While the epidemic disease is readily controlled by sanitary measures, these are not available under primitive conditions, and should such preventive measures break down on any large scale, the rapidity of travel customary in the 20th century would make possible the spread of cholera in pandemic proportions in a matter of a few weeks or months.

The Cholera Vibrio.—Although Félix Pouchet reported finding vibrios in the stools of cholera patients as early as 1849, it was not until 1883 that the causal agent of the disease was isolated and studied by the German bacteriologist Robert Koch. He cultured a small, slightly curved bacillus from the dejecta of cholera patients, first in Cairo and the following year in India, now known as *Vibrio cholerae*. Its aetiologic relation to the disease was suggested by its occurrence in enormous numbers in the stools of infected persons, substantiated by fatal infection of the guinea pig on intragastric inoculation and proved beyond reasonable doubt by accidental laboratory infections of man with pure cultures of the microorganism. The cholera vibrio is a member of a large group of gram-negative, comma-shaped bacteria that are morphologically indistinguishable from one another. This group is ordinarily divided into two parts, the one made up of the non-cholera vibrios, and the other of the cholera and choleralike or paracholera vibrios. The former includes a variety of saprophytic forms found in water and soil, together with some species that are pathogenic for lower animals, such as those producing a fatal septicaemia in birds, contagious abortion of sheep and the like. The members of the latter group are parasites of man, and the paracholera vibrios have been found with some frequency in association with mild diarrhoeal disease. The best known of the choleralike vibrios are the El Tor vibrios which were first isolated at the quarantine station at Tor (*see* map) in 1906 from pilgrims suffering from diarrhoea, and

FROM JORDAN AND BURROWS, TEXTBOOK OF BACTERIOLOGY (SAUNDERS)

APPROXIMATE DISTRIBUTION OF ASIATIC CHOLERA IN THE DECADE 1930 TO 1940

afterward were found repeatedly under similar circumstances. The question of the pathogenicity of these vibrios was raised again in the Celebes epidemic of 1938. The disease was identical with true cholera on clinical grounds, but was apparently caused by an El Tor vibrio; the development of the far eastern phase of World War II prevented

detailed study. It was urged by some workers that the paracholera vibrios associated with diarrhoeal disease in man are variants of the true cholera vibrio, and that the transformation is reversible; this theory was not generally accepted and the question of the relation of these forms to human disease was still an open one at mid-20th century.

The cholera vibrio is characterized physiologically by its rapid growth, requirement for free access to oxygen, tolerance of alkali and marked susceptibility to deleterious factors in the environment. It may be isolated from contaminated specimens by culture on a medium of high alkalinity. An enriched medium containing defibrinated blood or haemoglobin and adjusted to *p*H 9.5 is used; the best known of these media are Adolf Dieudonné's medium and that of Col. Edward Bright, G. A. Vedder and W. van Dam. Because of its relatively slight resistance the vibrio dies out in a matter of a few days at best on contaminated leafy vegetables and similar foods and does not persist in water so long as does the typhoid bacillus. The differentiation of the cholera vibrio from closely related vibrios is of considerable importance. While these vibrios commonly give the cholera-red or nitrosoindole reaction in nitrate-peptone water culture, and usually ferment sucrose and mannose but not arabinose, strains are biochemically heterogeneous and cannot be identified on the basis of cultural reactions alone. They are, however, closely related immunologically in that they contain a common heat stable somatic *O* antigen and fall into a serologic group designated *O* subgroup I; provisional identification may be made by agglutination with monospecific antiserum. Certain of the El Tor vibrios are members of this group also, but the El Tor vibrios form a soluble haemolysin acting on goat red blood cells while the cholera vibrios do not. The two may be differentiated by the Greig test in which equal volumes of peptone water culture of the vibrio and a 5% suspension of goat erythrocytes are mixed, incubated and read for haemolysis. The cholera vibrio is, therefore, defined as a nonhaemolytic vibrio of *O* subgroup I. Serologic types of the cholera vibrio, arising from minor differences in the *O* antigen and demonstrable by the use of absorbed antiserums, were described by Japanese workers in 1913 and 1921. These were designated the Inaba or original type, the Ogawa or variant type, and the Hikojima or middle type. The first two are distinct from one another and the last is related to both end types. These serologic types do not differ in pathogenicity.

Cholera in Man.—Under natural conditions cholera is exclusively a disease of man. Susceptibility of individuals varies widely and is markedly influenced by predisposing factors such as low gastric acidity and gastrointestinal disturbance arising from purging, alcoholism, infection with other enteric bacteria and the like. The vibrio enters the body via the mouth, usually in contaminated water or food, and sets up an infection in the small intestine, seldom penetrating the tissues beyond the superficial layers of the mucosa. The incubation period is short, probably never longer than five days and sometimes less than one. The vibrio does not form an extracellular toxin, but the cell substance is toxic, and with proliferation and disintegration of the vibrios within the lumen of the bowel, the endotoxin is liberated and symptoms appear. The disease usually develops in three relatively well-defined stages; the stage of evacuation, the stage of collapse or algid stage and the stage of reaction. The onset is usually abrupt and characterized by a purging diarrhoea followed by copious vomiting. The lower bowel is emptied of faecal matter early in the disease, and the stool takes on the typical rice-water appearance, a nonoffensive, whitish, opaque, albuminous fluid containing flakes of mucus and having a slight albuminous odour. The diarrhoea is both profuse and frequent, is painless without colic or tenesmus and is sometimes described as a literal pouring away of pints of pale fluid. The stomach is emptied at the onset of vomiting, the vomitus soon assumes the same appearance as the stools and may contain cholera vibrios, and there is exhaustive retching and hiccough. With the cumulative dehydration and loss of fixed base, agonizing cramps occur in the muscles, especially of the legs and feet, and sometimes of the arms, abdomen and back, and the sense of prostration is extreme. This stage lasts from 2 hr. to 12 hr., and its duration is inversely related to the severity of the symptoms. It passes insensibly into the algid stage characterized by almost continuous purging and vomiting and extreme collapse. The appearance of the patient changes rapidly, the skin becomes lax, wrinkled and cold and clammy to the touch, and the classic cholera facies appears, with eyes sunken, cheeks hollow and cyanosis about the eyes and lips; the voice becomes husky and the expression anxious and apathetic. The blood pressure falls, the pulse cannot be felt at the wrist and the urine is suppressed. Death may occur from circulatory failure or from asthenia. With cessation of vomiting and diarrhoea the patient enters the stage of reaction which, if the duration of the algid stage has been only a few hours, is that of recovery with restoration of blood pressure, disappearance of cyanosis, and flow of urine.

If the impairment of renal function has been serious with damage to the kidney parenchyma, flow of urine is not resumed, and death may result in four to five days.

The pathology of the disease is sometimes attributed to the action of absorbed toxin, but is equally well accounted for on the basis of the extreme dehydration, hypochloraemia, acidosis and impairment of renal function. The severe dehydration results in a similarity between the patient with cholera and the one in shock, but it is not complete because plasma elements other than fluid and electrolytes are not lost in cholera. The specific gravity of the blood rises to as high as 1.064 with polycythaemia and disproportionate leucocytosis. The outstanding post-mortem changes are the marked rigidity, with almost immediate stiffening of the limbs after death, and the pronounced dehydration of the tissues, though the body is usually well nourished because of the relatively short duration of the disease. Convalescence is commonly uneventful, with disappearance of vibrios from the stools in ten days to two weeks, but cardiac failure may result from slight exertion. The case fatality rate is usually 40% to 60% in untreated cases, but may be reduced to 10% to 20% by adequate treatment.

Treatment is both symptomatic and specific. The former is directed toward the replacement of fluid, the maintenance of blood and tissue chloride and the counteraction of acidosis. This may be achieved through the intravenous administration of hypertonic alkaline salt solution. Sterile stock solutions of hypertonic saline, alkaline saline, alkaline hypotonic saline and bicarbonate are mixed in proportions indicated by the state of the patient, and the amount administered is determined by the degree of dehydration as shown by the specific gravity and pressure of the blood. Collapse is favourably affected by atropine and pitressin, and the pain of muscular cramps may be relieved by whiffs of chloroform. Use of morphine and alcohol in any form is avoided. Specific treatment, such as the therapeutic use of anticholera serum and the administration of potassium permanganate or kaolin for neutralization of the toxin, has been disappointing, although cholera bacteriophage by mouth seems to have some small favourable effect. Certain drugs of the sulfonamide group, especially sulfaguanidine, were given extensive trial in Indian clinics with, on the whole, encouraging results, and the chemotherapy of cholera appears promising.

A majority of cases of cholera, especially during an epidemic, can be diagnosed on clinical grounds alone, and during an epidemic all suspected cases should be treated as cholera, and all contacts as potential cases. Diagnosis of the isolated case is more difficult, but the more important from the public health point of view. The disease may be confused with fulminating bacillary dysentery, with the algid and choleraic forms of malaria, trichinosis, food poisoning of staphylococcal or streptococcal aetiology, mushroom poisoning or poisoning with antimony or arsenic. The bacteriological diagnosis of cholera is dependent upon the isolation and identification of the vibrio. The demonstration of typical vibrios in a gram-stained smear from a flake of mucus is suggestive, and the vibrio may be isolated by culture on a selective medium and identified by agglutination with specific *O* antiserum and a negative reaction to the Greig test.

Immunity.—Infection with the cholera vibrio provokes an immune response as indicated by the appearance of bacteriolysins, agglutinins and other antibodies in the blood serum. Immunity to subsequent infection is not of a high order, however, nor does it persist for more than one to two years at the most. Prophylactic immunization was practised almost from the time of the discovery of the cholera vibrio, beginning with the work of Jaime Ferran in Spain and that of Waldemar Haffkine in India. A variety of immunizing preparations was used, including living vibrios, bacteriophage lysate and bilivaccine by mouth as well as the usual type of vaccine Modern vaccines consist of suspensions of cholera vibrios killed by heat or phenol in isotonic saline in a concentration of 8,000,000,000 per millilitre and are administered in two parenteral inoculations of 0.5 and 1.0 ml. one week apart. The vaccines used in India contained the Inaba type only, but bivalent vaccines containing equal proportions of the Inaba and Ogawa types are widely used. Immunity appears as early as the third to fifth day after inoculation but is effective for less than a year, and reinoculation should be practised at intervals of six months. The results of phophylactic inoculation have been to some degree conflicting. For example, an extensive immunization program carried out in Indochina in the 1930s apparently produced no immunity to the disease, but field studies in India consistently gave encouraging results. In such a study carried out in Madras during the severe epidemic of 1941-42 the incidence of the disease was reduced more than 90% by prophylactic immunization.

Immunization does not, however, reduce the severity of the disease in the individual.

Epidemiology and Control.—The dissemination of cholera is dependent upon connecting links between infected faecal material and the mouths of susceptible persons. The vehicle is most often water, but the disease is also transmitted by foods consumed in the raw state and by direct or indirect personal contact. The explosive character of the epidemic is attributable to the simultaneous infection of large numbers of persons, as by a common water supply, coupled with the short incubation period, and its dramatic aspect is accentuated by the high case fatality rate. When the epidemic has run its course in a nonendemic area, the disease dies out completely because of the fragility of the vibrio and the absence of the chronic carrier state in cholera, and subsequent epidemics are dependent upon reimportation of the infection. In endemic areas, however, the infection persists in a smouldering form and, while the mechanism of its maintenance is not altogether clear, it is highly probable that it depends on the occurrence of mild cases of the disease transmitted from person to person under the relatively primitive conditions prevailing. For example, in India water is stored in tanks which serve for the disposal of faecal material and as a source of water for washing and drinking purposes; such water supplies are seldom protected by the usual sanitary measures such as chlorination, filtration or other means of purification. Habitual defeca-

tion in open fields about inhabited areas and the use of fresh night soil as fertilizer in truck gardens makes possible dissemination of the infection by flies, on the surfaces of leafy vegetables and the like. Under ordinary circumstances spread of the disease into Europe is prevented by inspection at the quarantine stations at Tor and Basra (*see* map), and it is readily controlled by the usual sanitary practices, especially water purification and sewage disposal. This was strikingly illustrated in the Balkan War in 1913 in which infection was widespread in the Bulgarian army about Sofia, but cases in the capital were largely imported and the disease showed little tendency to spread; Sofia was efficiently sewered and had an excellent water supply.

Ultimate control of the disease depends upon the development of a higher standard of living in the primitive parts of the far east, and under ideal conditions cholera could probably be stamped out entirely.

CHOLET, a town of western France, capital of an *arrondissement* in the department of Maine-et-Loire, 33 mi. E.S.E. of Nantes. Pop. (1946) 26,086. Cholet stands on high ground on the right bank of the Le Moine, which is crossed by a 15th-century bridge. Megalithic monuments are numerous in the neighbourhood. The town owes the rise of its prosperity to the settlement of weavers there by Edouard Colbert, count of Maulévrier, a brother of the great Colbert. It suffered severely in the War of La Vendée of 1793. A public garden occupies the site of the old castle. The town possesses a sub-prefecture, a tribunal of first instance, a chamber of commerce and a board of trade-arbitrators.

There are granite quarries in the vicinity. The chief industries are the manufacture of linen and of preserved foods. Cholet is an important centre for the sale of fat cattle, sheep and pigs, for which Paris is the chief market.

CHOLON ("great market"), a town of French Indo-China, the largest commercial centre of Cochin-China, 3½ mi. S.W. of Saigon, with which it is united by railway, tramways, roads and canal. Cholon was founded by Chinese immigrants about 1780 and is situated on the *Arroyo Chinois* at the junction of the Lo-Gom and a canal. Its waterways are frequented by innumerable boats and lined in some places with native dwellings built on piles, in others by quays and houses built by the French, who have also carried out drainage schemes, installed electric lighting in the main streets and erected factories, schools, hospitals and administrative buildings. Its population is almost entirely Asiatic. In 1880 the population was 45,000; in 1936 it was about 145,000. Of these about half were Chinese, divided into congregations according to their place of origin. During the rice season the town is visited by a large floating population. Pre-1941 Cholon had a municipal council, composed of French, Annamese and Chinese traders. An administrator of native affairs, nominated by the governor, fills the office of mayor.

The rice trade, almost monopolized by the Chinese, is the leading industry.

Tanning, dyeing, copper-founding, glass, brick and pottery manufacture, stone working, timber sawing and junk building are other industries.

CHOLONAN, a linguistic stock of South American Indians, so called from the Cholones, its most important tribe. The Cholonan Indians live in eastern Peru, between the eastern crest of the Andes and the upper Huallaga river, from the Monzon in the south to the Mayo in the north. Missions were established among them in the 17th century, so that they have now largely lost their original culture. They are sedentary agriculturists, and still retain the use of the blow-gun, widely distributed among the neighbouring tribes to the north and east.

They live in cane-walled, thatched-roof houses, but, unlike their neighbours to the north and east, do not use the hammock for sleeping.

They appear to have had elaborate puberty ceremonies for the young men.

See E. Poeppig, *Reise in Chile, Peru und auf dem Amazonenstrome*, etc. (Leipzig, 1835).

CHOLULA, an ancient town of Mexico, in the state and on the plateau of Puebla, eight miles by rail W. by N. of the city of that name, and situated about 6,912 ft. higher than sea level. Pop. (1940) 8,424. The city's commercial and industrial standing is overshadowed by that of its larger, more modern neighbour, with which it is connected by tramway. At the time of the Spanish conquest, Cholula—then known as Cholollan—was a large and important town, consecrated to the worship of the god Quetzalcoatl, who had here one of the most imposing temples in Anahuac, built on the summit of a truncated pyramid, the largest of its kind in the world. This pyramid, constructed of sun-dried bricks and earth, 177 ft. high, and covering an area of nearly 45 ac., is the most conspicuous object in the town and was built probably as an imposing site for a temple. Nothing definite is known of its age and history, as the fanatical zeal of Cortés and his companions destroyed whatever historical data the temple may have contained. Cholula was visited by Cortés in 1519 during his eventful march inland to Montezuma's capital, Tenochtitlán, when he treacherously massacred its inhabitants and pillaged the city, pretending to distrust the hospitable inhabitants. Cortés estimated that the town then had 20,000 habitations, and its suburbs as many more, but this was undoubtedly a deliberate exaggeration. The Cholulans were of Nahuatl origin and were semi-independent, yielding only a nominal allegiance to Montezuma. They were a trading people, holding fairs, and exchanging their manufactures of textiles and pottery for other produce. The pyramid is believed to have been built by a people occupying this region before the Cholulans.

CHOPIN, FRÉDÉRIC FRANÇOIS (1810–1849), Polish musical composer and pianist, was born at Zelazowa-Wola, near Warsaw, on Feb. 22, 1810 (*not* Mar. 1, 1809). His father, of French origin, born at Nancy in 1770, had married a Polish lady, Justine Krzyzanowska. Frédéric was their third child. His first musical education he received from Adalbert Ziwny, a Czech musician, who is said to have been a passionate admirer of J. S. Bach. He also received a fair general education at the recently-founded Lyceum of Warsaw, where his father was professor of French. His musical genius opened to Chopin the best circles of Polish society, at that time unrivalled in Europe for its ease of intercourse, the beauty and grace of its women, and its liberal appreciation of artistic gifts. These early impressions were of lasting influence on Chopin's development. While at school he received thorough instruction in the theory of his art from Joseph Elsner, a learned musician and director of the conservatoire at Warsaw. When in 1829 he left his native town for Vienna, where his *début* as a pianist took place, he was in all respects a perfectly formed and developed artist. There is in his compositions little of that gradual progress which, for instance, in Beethoven, necessitates a classification of his works according to different periods. Chopin's individuality and his style were distinctly pronounced in that set of variations on "La ci darem" which excited the wondering enthusiasm of Robert Schumann. In 1831 he left Vienna with the intention of visiting London; but on his way to England he reached Paris and settled there for the rest of his life. Here again he soon became the favourite and musical hero of society. His connection with Mme. Dudevant, better known by her literary pseudonym of George Sand (*q.v.*), is an important feature of Chopin's life. When in 1839 his health began to fail, George Sand went with him to Majorca, and it was mainly owing to her tender care that the composer recovered his health for a time. Chopin declared that the destruction of his relations with Mme. Dudevant in 1847 broke up his life. The association of these two artists has provoked a whole literature of the nature of their relations, of which the novelist's *Un Hiver à Majorque* was the beginning. The last ten years of Chopin's life were a continual struggle with the pulmonary disease to which he succumbed in Paris Oct. 17, 1849. The year before his death he visited England, where he was received with enthusiasm by his numerous admirers.

Chopin died in the arms of his sister, who hastened from Poland to his death-bed. He was buried in the cemetery of Père Lachaise.

In looking through the list of Chopin's compositions, teeming

with mazurkas, valses, polonaises, and other forms of national dance music, one might hardly suppose that here one of the most melancholy natures revealed itself. This seeming paradox is explained by the type of Chopin's nationality, of which it has justly been said that its very dances are sadness intensified. Yet notwithstanding its strongly pronounced national characteristics, Chopin's music is always expressive of his individual feelings and sufferings in the highest possible degree. He is indeed the lyrical composer *par excellence*, and the intensity of his expression finds its equal in literature only in the songs of Heinrich Heine, to whom he has been so often likened. Such high-strung passion cannot be prolonged, and hence it was in works of small compass, such as the nocturne and the étude, that Chopin found the happiest expression of his genius. In compositions of larger scope he was out of his element, and even the beauty of his melodies and harmonies cannot wholly banish the impression of incongruity. Fortunately, he himself had an unerring sense of his own limitations, though there could be no greater mistake than to suppose that because he wrote in the smaller forms he was not, even so, one of the greatest of masters. Chopin's piano-playing was as exquisite as his music, and many accounts left by his contemporaries have testified to the irresistible fascination which he exercised by performances described as the last word in delicacy, subtlety and refinement.

It is well to sift the posthumous works from those published under Chopin's direction, for the last three mazurkas are the only things he did not keep back as misrepresenting him. On these principles his mature works are summed up in the 42 mazurkas (Opp. 6, 7, 17, 24, 30, 33, 41, 50, 56, 59, 63, and the beautiful contribution to the collection *Notre temps*); seven polonaises (Opp. 26, 40, 53, 61); 24 preludes (in all the major and minor keys), Op. 28, and the single larger prelude, Op. 45; 27 études (12 in Op. 10, 12 in Op. 25, and 3 written for the *Méthode des méthodes*); 18 nocturnes (Opp. 9, 15, 27, 32, 37, 48, 55, 62); 4 ballades, in forms of Chopin's own invention (Opp. 23, 38, 47, 52); 4 scherzos (Opp. 20, 31, 39, 54); 8 waltzes (Opp. 18, 34, 42, 64); and several pieces of various description, notably the great fantasia, Op. 49, and the impromptus, Opp. 29, 36, 51. The posthumous works number 35 pieces, besides a small volume of songs a few of which are of great interest.

The editions of Chopin's works by his pupil Mikuli and by Klindworth are full of valuable elucidation as to methods of performance, but unfortunately they do not distinguish the commentary from the text. The critical edition published by Breitkopf and Härtel, with all its mistakes, is absolutely necessary for students who wish to know what Chopin wished to put into the hands of players of independent judgment.

BY COURTESY OF THE TRUSTEES OF THE BRITISH MUSEUM

CHINESE CHOPSTICKS. TO THE LEFT IS A LONG, SLENDER KNIFE WITH ITS ENGRAVED CASE

The Chopin literature is very extensive. The standard biography is the English work of Prof. F. Niecks (1888), while other leading works are those by Liszt, Karasowski and Huneker. *See* also W. H. Hadow, *Studies in Modern Music*, Henry Bidou, *Chopin* (1927) and G. Ashton Jonson's useful *Handbook to Chopin's Works*.

CHOPSTICKS, the "pidgin-English" name for the pair of small tapering sticks used by the Chinese in eating. (Chinese ***kwai-tse*** "the quick ones," "chop"-quick.) They are made of wood, bone, or ivory, somewhat longer and thinner than a lead-pencil. Held between the thumb and fingers, they are used to take up portions of food, cut up into small pieces. Many rules of etiquette govern the proper conduct of the chopsticks; laying them across the bowl is a sign that the guest wishes to leave the table; they are not used during a time of mourning, when food is eaten with the fingers; and various methods of handling them form a secret code of signalling.

CHORALE, a term in music used by English writers to indicate the hymn-tunes composed or adopted for use in church by the German reformers (Lat. *Choralis*). German writers, however, apply the terms "Choral" and "Chorale-geesang," as Luther himself would have applied them, to any solemn melody used in the church. It is thus the equivalent of canto fermo; and the German rhymed versions of the biblical and other ancient canticles, such as the Magnificat and the Te Deum, are set to curious corruptions of the corresponding Gregorian tunes, which adaptations the composers of classical German music called chorales with no more scruple than they applied the name to tunes of secular origin, German or foreign. The peculiarity of German chorale-music, however, is that its use, and consequently much of its invention, not only arose in connection with the Reformation, by which the liturgy of the church became "understanded of the people," but also that it belongs to a musical epoch in which symmetry of melody and rhythm was beginning to assume artistic importance. The growing sense of form shown by some of Luther's own tunes (*e.g., Vom Himmel hoch, da komm' ich her*) soon advanced, especially in the tunes of Crüger, beyond any that was shown by folk-music; and it provided a massive bulwark against the chaos that was threatening to swamp music on all sides at the beginning of the 17th century.

By Bach's time all the polyphonic instrumental and vocal art-forms of the 18th century were mature; and though he loved to derive the design as well as the details of a large movement from the shape of the chorale tune on which it was based, he became quite independent of any aid from symmetry in the tune as raw material. The chorus of his cantata "Jesus nun sei gepreiset" is one of the most perfectly designed and quite the longest of movements ever based upon a chorale-tune treated phrase by phrase. Yet the tune is one of the most intractable in the world, though its most unpromising portion is the basis of the most impressive feature in Bach's design (the slow middle section in triple time.)

In recent times the great development of interest in folk-music, and the discovery of the unique importance of Bach's work, have combined to tempt writers on music to over-estimate the distinctness of the art-forms based upon the German chorale. There is really nothing in these art-forms which is not continuous with the universal practice of writing counterpoint on a canto fermo. Thus Handel in his Italian and English works wrote no entire chorale movements, yet what is the passage in the "Hallelujah" chorus from "the kingdom of this world" to the end, but a treatment of the second part of the chorale "Wachet auf"? Again, to return to the 16th century, what are the hymns of Palestrina but figured chorales? In what way, except in the lack of symmetry in the Gregorian phrasing, do they differ from the contemporary setting by Orlando di Lasso, also a Roman Catholic, of the German chorale "Vater unser im Himmelreich"? In later times the use of German chorales, as in Mendelssohn's oratorios and organ-sonatas, has had rather the aspect of a revival than of a development; though the technique and spirit of Brahms's posthumous organ chorale-preludes is thoroughly modern and vital.

One of the most important, and practically the earliest collection of "Chorales" is that made by Luther and Johann Walther (1496–1570), the "Enchiridion," published in 1524. Next in importance we may place the Genevan Psalter (1st ed., Strasbourg, 1542, final edition 1562), which is now conclusively proved to be the work of Bourgeois. From this Sternhold and Hopkins borrowed extensively (1562). The psalter of C. Goudimel (Paris, 1565) is another among many prominent collections showing the steps towards congregational singing, *i.e.*, the restriction to "note-against-note" counterpoint (*sc.* plain harmony), and, in 12 cases,

the assigning of the melody to the treble instead of to the tenor. The first hymn-book in which this latter step was acted on throughout is Osiander's "Geistliche Lieder . . . also gesetzt, das ein christliche Gemein durchaus mitsingen kann" (1586). But many of the finest and most famous tunes are of much later origin than any such collections. Several (*e.g.*, "Ich freue mich in dir") cannot be traced before Bach, and were very probably composed by him. (D. F. T.)

CHORAL SINGING. In Great Britain choral singing, from 1913 to 1928, falls into three periods—the splendid activity which was checked by the World War, the struggles during that dark period, and the efforts since 1919 to find means of meeting the new situation. In the first period there was extraordinary vitality and much new impetus.

Some Notable Figures.—The old tradition of solid, square-toed choralism had been shaken to the roots by the personality of Dr. (now Sir) Henry Coward, the Sheffield chorus master. He had turned the big, heavy, unwieldy body of the provincial choral society into a living, sensitive, functioning organism, and his exploits had created a sensational interest in this form of art. Some of his disciples, no doubt, carried his ideas too far and lost sight of the end in exploiting the means. There were other notable workers in the field, with different aims, each contributing to the general good. Harry Evans, by his work in Wales and Liverpool, his keen personality and penetrating insight, made a great impression on the choral world. He was particularly successful in modern works for large choirs, exploiting vivid colouring. His comparatively early death in 1914 was a severe loss.

Two other choirs, also under men of outstanding personality, were beginning to attract attention. Both were breaking away from the lines traditionally followed by the average British choral society. In 1904 Charles Kennedy Scott, an able and versatile musician, founded in London the Oriana Madrigal Society, a small body originally intended to arouse interest in the English madrigal school. It eventually widened its scope and devoted much attention to modern British unaccompanied choral works, and in the period in question it was becoming firmly established in public notice. The choice of programmes struck out new lines and gave fresh ideas to choral conductors all over the world.

In Glasgow an amateur musician, Hugh S. Roberton, was attracting attention by the skilled singing of his Orpheus Choir, a body of about 120 singers, concentrating mostly on Scottish song arrangements and unaccompanied works on a small scale. Dr. E. C. Bairstow, organist of York Minster since 1913, was proving himself one of the most able choral conductors in the land, and a church musician who made the services at the Minster among the finest of the world.

The period being described was also remarkable for experiments in choral composition. The new technique acquired by large choral societies and the enormous strides made by choirs in touch with the competition festival movement opened up new possibilities to composers. The most daring experimentalist was Sir Granville Bantock, who wrote (1912–14) *Atalanta in Calydon* and *The Vanity of Vanities*. Entitled choral symphonies, they are divided into four movements on the lines of the traditional orchestral form, and are written for unaccompanied voices. The voices are disposed in 20 and 12 parts respectively, not with a view to polyphonic writing, but to obtain contrasts of colour on the lines of strings, wind and brass of the orchestra. Many highly original effects are obtained, and severe problems set for choir and trainer.

Recent Developments.—On the conclusion of the World War the task of reconstruction proved even greater than had been anticipated. Traditions had been broken and the formerly constant supply of tenors and basses was not and has not been recaptured. Subscribers who had supported institutions for many years as a duty did not resume their help. The war, too, had accelerated a change of taste which had gradually been coming about. Standard societies had always been able to rely upon the popular oratorios of Handel and Mendelssohn to crowd houses and fill coffers. *The Messiah* had paid many and many a deficit. But, generally speaking, this was no longer the case. Moreover, costs of halls, orchestra, printing and advertising, were all higher, and in addition there was the devastating entertainment tax. Consequently few societies could meet their expenses.

On the other side of the account, however, there was a new awakening of competition festivals, which, firmly established before the war, have attained an extraordinary vitality since. One great value of this movement is that it affords a *raison d'être* for the existence of every kind of society, except the larger bodies. Rural festivals bring into existence choirs in the smallest of villages, and the larger festivals stimulate the virtuosity of the leading bodies. Choirs connected with churches and chapels, women's institutes, guilds, boy scouts, all sorts of male, female and mixed organizations, are encouraged, improved and given a new outlook. In this way the problem of finding an audience for a concert and making ends meet may be avoided.

There has been a remarkable development of male voice choirs, mostly of working men, often connected with factories or works of various kinds, and these have, to a certain extent, thinned the male ranks of mixed choirs. A keen sense of sportsmanship and comradeship results in much more intensive work than is customary with mixed choirs. "Trade" bodies were willing to submit to 60 or 70 rehearsals of a single part song. A much higher standard of music is now obtained through the influence of these festivals. The singing of madrigals has received an immense impetus. Choral arrangements of folk songs and compositions by the best of our modern composers are being brought within the ken of many thousands of people. For some festivals choirs prepare choruses from an important work which is finally given by combined forces. In this way tiny rural villages know their Bach cantatas, and are even intimate with the B minor Mass and other large-scale compositions.

Another striking development of importance has been the growth of "works" choirs, some of which are very fine bodies. The Glasgow police and tramways choirs and the L.N.E.R. Musical Society are examples. One interesting fact is being disclosed by this activity. It was thought that the best choral singing was to be found only in Yorkshire, and that other parts of the country could not hope to rival that county. But the opinion of most adjudicators is that first-rate work can be produced anywhere. Without doubt the most robust voices come from this northern county, and in other parts of the country the current quality is less adapted to powerful and brilliant results, but a good conductor can produce superlatively good results from material existing in any district in the British Isles. Adjudicators of the widest experience have found astonishing results in places which were supposed to be unmusical. The general consensus of opinion among critics at the Leeds festival of 1925 was that although vocally the choir there was perhaps the finest in the world, technically it was inferior to many bodies in other parts of the country. This change of centre foreshadows a new era in choral singing.

Some Notable Choirs.—In London the Oriana Choir continues to do good work, forming a model for madrigal singing, and producing the latest works of modern British composers. In 1919 the Philharmonic Choir was formed in order that a large choral body might be affiliated with the Philharmonic Society. Kennedy Scott was appointed conductor, and he had proved as brilliant with a large choir as with a small one. Among the important works produced, in addition to classics, have been Bax's motets and the choral works of Delius. In particular, the performance of the *Mass of Life* in April 1925, reached a remarkable standard. London possesses, for the first time in its history, both a large and a small choir which can give performances unexcelled anywhere else in the kingdom. A junior philharmonic choir, composed of young women, is now in existence. Besides giving concerts of its own, it forms a source from which experienced singers can be drafted into the main body.

In Scotland.—The Glasgow Orpheus Choir has reached a state of popularity unprecedented in the history of choral singing, and maintains the level of its superlatively polished performances. It attracts crowded audiences in Glasgow, gives concerts all over Scotland, and makes annual raids into England. It has done

much to stimulate choral singing; its policy has been to afford opportunities for the training of conductors, and to give advice and assistance on the question of formation of new choirs. It is probably the first time that any choir has undertaken missionary work on such a large scale. A most successful tour was made in Canada and the United States of America, in the summer of 1926, and the reputation of British choral singing was brilliantly enhanced. In Manchester the Hallé Choir (chorus master, Mr. Dawber) has within late years won fresh honours at the concerts conducted by Sir Hamilton Harty.

Changes of Taste.—A significant feature in recent years has been the greatly increased interest in Bach. At the beginning of the century Bach was considered suitable for only the finest choirs, and especially cultured audiences. His cantatas were almost unknown in Britain. Now large and small societies produce his larger works frequently, and his church cantatas are being regularly performed. Reference may be made in this connection to an experiment, the founding of the Newcastle-upon-Tyne Bach Choir in 1915 to perform the works of the master, not with the wrong proportions of an orchestra of 50 and a choir of 300, but with forces approximating to those used in his day. The choir, after a period of experiment, was fixed at 40, ten to a line. The orchestra varies according to the work concerned; in some cases it is practically equal to the choir in numbers. Besides all the large works of Bach and the motets, about 80 of his cantatas have been given. A three days' Bach festival was given in London in Feb. 1921. British composers are also included in the scheme of work, over 60 having been represented. It gave in Newcastle cathedral in 1924 the first known complete performance of Byrd's recently discovered *Great Service*, and the Carnegie United Kingdom Trust sent the choir to give three performances of it in St. Margaret's, Westminster, London, in November of the same year. Several choirs have been formed on its lines, in Doncaster, Stockton, Leicester, Liverpool, and are helping to spread a knowledge of Bach unrivalled in any other country outside Germany if, indeed, that country is not now outdistanced in this direction by Great Britain. A Bach Cantata Club began operations in London in Feb. 1926, under the direction of C. K. Scott.

The Newcastle-upon-Tyne Bach Choir was invited to sing at the festival of the International Society for Contemporary Music, in Frankfurt-on-Main in July 1927, and afterwards made a short tour of German university towns, singing unaccompanied British music ranging from Byrd to Holst.

Advance in Technique.—It is impossible in a short article even to mention all the manifestations of choral singing throughout Great Britain. As a result of the competition festival movement, new conductors of merit are appearing everywhere. Works which, a few years ago, were looked upon as extremely difficult, for instance, Elgar's *Gerontius*, are now sung in many small towns. The work in question will receive 50 to 60 performances every winter. To take a single example, an isolated town like Kendal, with a population of 14,000, can produce such works as Holst's *Cloud Messenger* and Vaughan Williams' *Sea Symphony*.

At the same time the improved standard of choral singing has inspired a series of fine works by British composers. Vaughan Williams' unaccompanied *Mass*, and his oratorio, *Sancta Civitas*, Holst's *Hymn of Jesus* and first choral symphony, and a remarkable group of unaccompanied motets by Arnold Bax, are a tribute alike to the technical efficiency of choral bodies and to the vitality and high level of the great tradition of native compositions for choirs.

Community singing has been another development of the movement and was inaugurated in 1915 on the lines of successful gatherings in Australia. Meetings were organized at which folk, national, and simple classical songs were sung in unison, and easy rounds were rehearsed, the music being taught by pattern, so that no technical knowledge was demanded from the singers. This "caught on" in a remarkable way, and the movement promises to become a permanent feature of national life, closely allied with the folk dance revival. Notable leaders are Gibson Young (who was one of the prime movers in Australia), Geoffrey Shaw, Sir Richard Terry, and Sir Hugh Allen.

In the Dominions.—British choirs overseas bid fair to follow the good example of the Mother Country. Dr. Fricker, late of Leeds, is doing splendid work in Toronto. The Winnipeg Male Voice Choir, under Hugh Ross (since conductor of the Schola Cantorum in New York) impressed visiting adjudicators greatly. British adjudicators returning from recent competitive festival tours, report that choral activity may outdistance the Mother Country in a short time, and speak enthusiastically of a remarkable standard of performance. Possibly by virtue of its climate, Australia produces splendid women's voices, which rather overweigh the men's. South Africa is producing some astonishing results with native races, especially in schools, where early maturity enables fully fledged four-part singing to be cultivated. There is much choral activity in the main centres of that continent. (W. G. W.)

THE UNITED STATES

The early growth of choral music in the United States, as elsewhere, was associated with the Church. It was the Puritans of New England rather than the Dutch colonists of New York who were mainly responsible for the earliest developments, and this although the Pilgrim fathers brought to America a hatred of musical culture that is without parallel in history. Over a century of controversy was required, indeed, before the Church reluctantly accepted organized singing in "the new and ruleable way," which simply meant singing from the printed page rather than constantly repeating the traditional tunes from memory. Even late in the 18th century some localities still sang in "the usual way," which often consisted of the congregation's singing parts of two or three different tunes to one stanza of a hymn, or even singing different tunes at the same time. These melodies were sung so slowly that it was often necessary to take breath twice on one and the same tone or word-syllable.

In the face of such a handicap, it is surprising that early choral singing developed as rapidly as it did. But the acceptance of organized singing in the Church brought with it the advent of the singing school, with its psalm-tune teacher, and thereafter the choral society was a natural development. An early, but it must be admitted not too well authenticated, report describes a performance of the *Messiah* with organ accompaniment in the New York Trinity church as long ago as Jan. 9, 1770, less than 28 years after the original production of the work.

Early Organizations.—Probably the first stable organization of amateur singers in America was the Stoughton Musical Society, founded in Stoughton, Mass., by the first American composer, William Billings, in 1786. This antedates by five years the famous Berlin *Singakademie*. A rapid growth of similar choral societies followed, so that by 1812 the regularly established amateur choruses in America already outnumbered those of Germany, although the latter were doubtless vastly superior in quality. Of more lasting influence than the Stoughton Society was the Handel and Haydn Society, founded in Boston in 1815. This, while it lasted, became to America what the *Singakademie* of Berlin was to Continental Europe—the model for all similar organizations throughout its native country. It may be added that this society, whose present conductor is Thompson Stone, actually negotiated with Beethoven for a new choral work.

Henceforward, choral societies appeared in rapid succession. The short-lived Handel and Haydn Society of New York gave way to the New York Choral Society and the New York Sacred Music Society, both established in 1823, though the former only lasted a year. In 1844 the Musical Institute of New York was founded, but by 1850 it was saved only by an amalgamation of the three New York choral groups, the Vocal Society, the Sacred Music Society and the American Musical Institute, all combining to form the New York Harmonic Society. As a result of a controversy the short-lived Mendelssohn Society was formed in 1863, but nothing of a permanent nature was established until 1873, when Dr. Leopold Damrosch organized the New York Oratorio Society, which remains to-day as probably the foremost choral organization in the United States.

In recent years the Harvard and Radcliffe Glee clubs have taken part in notable choral performances with the Boston Symphony orchestra under Koussevitzky.

New York Oratorio Society.—Starting with a group numbering from 15 to 20, and giving its first concert with only 60 voices, Dr. Damrosch lived to direct such a festival as that of 1881 when he conducted a chorus of 1,200 and an orchestra of 250. At his death the work was continued by his son Walter and later, for a short period, by Frank Damrosch. Louis Koemmenich, a German conductor, did much for the development of the Oratorio Society. After 1921 the society was under the leadership of Albert Stoessel, who, in its annual Christmas production of the *Messiah*, and performances of other compositions of the great classical masters, as well as of modern works, had continued the traditions of the organization. In 1927 the society gave the first complete performance in New York of Bach's *B Minor Mass*. The Oratorio Society shares with the more recent Schola Cantorum of New York, founded by Kurt Schindler in 1909 (Hugh Ross, conductor), the responsibility of providing New York with choral music.

It was due largely to the singing schools of New England that choral culture found its way to other sections of the country. In the west, Cincinnati became a choral centre, developing around the German population who were responsible for the first American *Sängerfest* in 1849, just four years after such reunions had been introduced in Würzburg, Germany. Theodore Thomas was responsible for the first of the famous Cincinnati festivals, in 1873. With one exception they have taken place biennially since that time. The director in 1931, 1933, 1935, 1937 and 1939 was Eugene Goossens.

Of eastern choral festivals, two are of outstanding importance. The annual Worcester (Mass.) music festival was established in 1858 under the name of Musical Convention. In 1873 it became the Worcester County Musical Festival. The annual Bach festival at Bethlehem, Pa., is devoted to the works of the great master, and was responsible for the first complete American performance of the *B Minor Mass*. To-day the choral societies in the United States are almost innumerable; Philadelphia alone boasts over 60, and the number of such bodies throughout the whole country is being added to every year.

(A. STO.)

CHORAL SYMPHONY, a symphony including choral movements or numbers. Beethoven's ninth symphony, with vocal finale for four solo singers and chorus, is the most famous of all such works. Another is Mendelssohn's *Hymn of Praise*. Among more recent composers Mahler wrote several choral symphonies.

CHORAZIN and **BETHSAIDA.** Towns in the neighbourhood of Capernaum (Mth. xi., 21; Lk. x., 13). Since the 18th century the former has been identified with a ruined site *Khirbet Kerāzeh* about 2 m. N. of *Tell Hūm* (Capernaum). Amongst the ruins are the remains of a synagogue built of black basalt. Scholars are divided as to whether *one* Bethsaida is to be sought or *two*. Those who favour one generally locate it east of the Jordan at *Et-Tell* or *El-'Ardj* (either site answering the description of Bethsaida-Julias of Josephus, *Antiq.* xviii. 2. 1) or at *Mas 'adiyeh*. Those who would look for a separate "Bethsaida of Galilee" (John xii., 21) have advocated variously *Tell Hūm, 'Ain et-Tābighah, Khirbet (Khān) Minyeh* or *'Ain et-Tīneh*. Now that *Tell Hūm* has been identified with Capernaum, the identification of *Khirbet Minyeh* with Bethsaida is being urged.

CHOREA: *see* ST. VITUS'S DANCE.

CHORIAMBIC VERSE or **CHORIAMBICS,** lyric verse based on the choriambus, a group of four syllables, – ∪ ∪ – (*i.e.*, choree or trochee+iamb). It is especially characteristic of Aeolic verse, as that of Alcaeus, Sappho, and their Latin imitator Horace, but is not confined to it. Regularly, one or more choriambi are preceded, or followed, or both, by other groups of syllables, as

hŏc dĕă ūĕ|rĕ Sўbărĭm | cŭr prŏpĕrās | ămāndō (Greater Sapphic).

ĭntĕgĕr ūĭ | tăe scĕlĕrĭs | quĕ pūrŭs (Sapphic hendecasyllable).

sĭc fră|trĕs Hĕlĕnae | lŭcĭdă sĭ|dĕră (Lesser Asclepiad).

tū nĕ | quaesieris | scīre nĕfās | quĕm mihĭ quĕm | tĭbĭ (Greater Asclepiad).

These and other varieties are arranged into various stanzas. These are essentially metres meant for song, not recitation, and are used to express emotion, serious or trivial. *See* GLYCONIC; SAPPHIC METRE.

Modern music often contains choriambi, but the few attempts at these in modern verse are mere *tours de force* as Gilbert Murray's:—

"ăn ōld | ēaglĕ, ă blīnd | ēaglĕ whŏ waĭts | hŭngrў ănd cōld | ănd stĭll."

CHORICIUS, of Gaza, Greek sophist and rhetorician, flourished in the time of Anastasius I. (A.D. 491–518). He was the pupil of Procopius of Gaza, who must be distinguished from Procopius of Caesarea, the historian. His declamations, often accompanied by commentaries, include, besides panegyrics, funeral orations, and stock themes, *Epithalamioi*, or wedding speeches. Choricius was also the author of so-called *Ekphraseis*, descriptions of works of art after the manner of Philostratus. His moral maxims were largely drawn upon by Macarius Chrysocephalas, metropolitan of Philadelphia (middle of the 14th century), in his *Rodonia* (rose-garden). A special feature of Choricius' style is the avoidance of hiatus, peculiar to what is called the school of Gaza.

Editions by J. F. Boissonade (1846, supplemented by C. Graux in *Revue de philologie*, 1877), and R. Förster (1882–94); *see* also C. Kirsten, "Quaestiones Choricianae" in *Breslauer philologische Abhandlungen*, vii. (1894); G. Pietsch, "De Choricio Patrocli declamationis auctore" in same publication (1910), and article by W. Schmid in Pauly-Wissowa's *Realencyklopädie*, iii. 2 (1899). On the Gaza school *see* K. Seitz, *Die Schule von Gaza* (Heidelberg, 1892).

CHORIN, AARON (1766–1844), Hungarian rabbi and pioneer of religious reform, born at Weisskirchen, Moravia, on Aug. 3, 1766, educated at Prague, and became rabbi at Arad in 1789. His *Emek ha Shaweh* (Vale of the Plain) of 1803 was declared heretical by the orthodox party, but he continued to favour such reforms as modification of the traditional laws, vernacular prayers, and the use of the organ. Chorin was also interested in the promotion of schools, seminaries, and professions among the Jews. He died on July 26, 1844.

See L. Low: *Gesammelte Schriften* vol. ii. (Szegedin, 1889).

CHORIZONTES ("separators"), the name given to the Alexandrian critics who denied the single authorship of the *Iliad* and *Odyssey*, and held that the latter poem was the work of a later poet. The most important of them were the grammarians Xeno and Hellanicus; Aristarchus was their chief opponent (*see* HOMER).

CHORLEY, a municipal borough, Chorley parliamentary division, North Lancashire, England, 22 mi. N.W. from Manchester, on the L.M.S.R. and the Leeds and Liverpool canal. Pop. (est. 1938) 30,140. Area, 6.7 sq.mi. The town is situated on the "fall-line" between a westward projection of the Pennines and the North Lancashire plain. The church of St. Lawrence is mainly Perpendicular and contains fine woodwork. Textiles, railway-wagon making and metal-working are the chief industries, but there are several coal mines and stone quarries. There is a large reservoir of the Liverpool corporation water works with a capacity for 48,300,000 gal. The beautiful Elizabethan mansion of Astley hall, with park, was presented to Chorley as a World War I memorial. The corporation bought Duxbury park (541 ac.) in 1932.

CHORLU or CORLU, a town of European Turkey, in the vilayet of Adrianople; on the left bank of the Chorlu, a small left-hand tributary of the Ergene, 25 mi. N.E. of Silivri on the Sea of Marmora, and about 75 mi. by rail from Istanbul. Population (1940) 16,979. Chorlu has a station on the Istanbul-Edirne railway.

It manufactures woollen cloth (*shayak*) and native carpets, and exports cereals, oilcloth, carpets, cattle, poultry, fresh meat, game, fruits, wine, alcohol, hides and bones.

CHOROGRAPHY. (1) A description or delineation on a map of a district or tract of country (from the Gr. χώρα, a tract of country, and γράφειν, to write). The word is common in old geographical treatises, but is now superseded by the wider use of "topography."

(2) A system of notation to indicate the steps and movements in dancing.

CHOROTEGA, a group of linguistically related Indian tribes located on the west coasts of Honduras (Choluteca), Nicaragua (Mangue), and Costa Rica (Orotiña). Other groups are found in southern Mexico. All have lost their tribal identity, although the Mangue dialect is still in existence. Archaeological evidence assigns to the Chorotega an important place in the aboriginal culture history of Central America, for early phases of the Chorotega underlie the most ancient remains of the Maya.

See S. K. Lothrop, "Pottery of Costa Rica and Nicaragua," *Contributions from the Museum of the American Indian, Heye Foundation,* vol. viii., 1926, p. 20–100.

CHOROTES, a tribe of South American Indians belonging to the Matacan (*see* MATACO) linguistic stock. The Chorotes live in southern Bolivia on the eastern side of the upper Pilcomayo river. They are a tall, long-headed folk, with a simple semi-nomadic type of culture. The dress of both sexes is a short kilt of skins or coarse woollen cloth. Today, at least, the Chorotes practise some agriculture. They live in small, rudely thatched huts. They have no canoes. The bow is the main weapon. Simple pottery and netted bags are made. Village chiefs are hereditary and have considerable power. The women select their husbands.

See E. Nordenskiold, *Indianerleben; El Gran Chaco* (Leipzig, 1913).

CHÓRUM or ÇORUM, the chief town, pop. (1950) 22,835, of the vilayet of the same name in Turkey, altitude 2,300 ft., on the edge of a plain, almost equidistant from Amasia and Yozgat. Pop. of vilayet (1950) 342,290. The ancient *Euchaïta,* 15 mi. E., was attacked by the Huns A.D. 508, and became a bishopric at an early period. It contained the tomb of the revered St. Theodore, who slew a dragon in the vicinity and became one of the great warrior saints of the Greek Church. (*See* J. G. C. Anderson, *Studia Pontica.*)

CHORUS (Gr. χορός), properly a dance, and especially the sacred dance, accompanied by song, of ancient Greece at the festivals of the gods. The word χορός seems originally to have referred to a dance in an enclosure, and is therefore usually connected with the root appearing in Gr. χόρτος, hedge, enclosure, Lat. *hortus,* garden, and in the Eng. "yard," "garden" and "garth." In the chorus sung in honour of Dionysus the ancient Greek drama had its birth. From that of the winter festival, consisting of the κῶμος or band of revellers, chanting the "phallic songs," with ribald dialogue between the leader and his band, sprang "comedy," while from the dithyrambic chorus of the spring festival came "tragedy." (For the history of the chorus in Greek drama *see* DRAMA: *Greek Drama.*)

The chorus as a factor in drama survived only in the various imitations or revivals of the ancient Greek theatre in other languages. A chorus is found in Milton's *Samson Agonistes.* The Elizabethan dramatists applied the name to a single character employed for the recitation of prologues or epilogues. Apart from the uses of the term in drama, the word "chorus" has been employed chiefly in music. It is used of any organized body of singers, in opera, oratorio, cantata, etc., and, in the form "choir," of the trained body of singers of the musical portions of a religious service in a cathedral or church. As applied to musical compositions, a "chorus" is a composition written in parts, each to be sung by groups of voices in a large body of singers. The word is also used of that part of a song repeated at the close of each verse, in which the audience or a body of singers may join with the soloist.

In the early middle ages the name *chorus* was given to a primitive bagpipe without a drone. Giraldus Cambrensis in his *Topographia Hiberniae* mentions it as one of the three instruments of Wales and Scotland, though there is some reason to believe that he may have been confusing it with the crot or crwth, an entirely different instrument. It is further recorded that King James I. of Scotland was renowned for his skill as a performer on various musical instruments, one of which was the chorus.

CHOSE, a term used in law in different senses. *Chose local* is a thing annexed to a place, as a mill. A *chose transitory* is that which is movable, and can be carried from place to place. But the use of the word "chose" in these senses is practically obsolete, and it is now used only in the phrases *chose in action* and *chose in possession.* A "chose in action," in its more limited meaning, denotes the right to sue for a debt or damages, whether arising out of a contract or a tort. Less accurately, the money itself which could be recovered is frequently termed a chose in action, as is also sometimes the document evidencing a title to a chose in action, such as a bond or a policy of insurance, though strictly it is only the right to recover the money which can be so termed. Choses in action were either *legal* or *equitable.* Where the chose could be recovered by an action at law, as a debt (whether arising from contract or tort), it was termed a legal chose in action; where the chose was recoverable only by a suit in equity, as a legacy or money held upon a trust it was termed an equitable chose in action.

The courts of Common law did not originally (except in the case of negotiable instruments) recognize the assignment of choses in action. Any attempt to assign a chose in action was invalid, and if the debtor paid the assignee, he could be compelled to pay the debt over again to the assignor. The only way in which a debt could be transferred was by a new contract of a trilateral nature in which the debtor was released by the assignor, and consented, in consideration of such release, to become liable to the assignee. This was a novation, not an assignment. But courts of equity at an early date gave effect to an assignment of a chose in action for valuable consideration, treating the assignee as an agent of the assignor with an irrevocable authority to collect and keep the proceeds. By the end of the eighteenth century the law courts adopted a similar doctrine permitting the assignee to sue in the assignor's name. *Winch* v. *Keeley,* 1 T.R. 619. In America statutes known as real party in interest statutes are common permitting the assignee to sue in his own name. In England under the Judicature Act of 1783 as amended by the Law of Property Act, 1925, permits the assignee to sue in his own name without joining the assignor, provided (a) the assignment was absolute and not by way of charge only; (b) the assignment was in writing; and (c) notice in writing was given to the debtor or party to be charged.

See Williston, Contracts, c. 14.

A chose in possession is opposed to a chose in action, and is a thing in actual physical possession. A chose in possession is freely transferable by delivery.

CHOSEN: *see* KOREA.

CHOSROES (koz'rō-ēz), in middle and modern Persian *Khosrau* ("with a good name"), a common name, borne by a king of the Iranian legend (Kai Khosrau); by a Parthian king, commonly called by the Greeks Osroes; and by the following two Sassanid kings.

1. CHOSROES I., "the Blessed" (*Anushirvan*), A.D. 531–579, successor of Kavadh I., and the most famous of the Sassanid kings. At the beginning of his reign he concluded an "eternal" peace with the emperor Justinian, who wanted to be free for the conquest of Africa and Sicily. But successes against the Vandals and Goths caused Chosroes to renew the war in 540. He invaded Syria and took Antioch, and during the next years fought successfully in Lazica or Lazistan (the ancient Colchis, *q.v.*), on the Black sea, and in Mesopotamia. In 545 an armistice was concluded and in 562 a peace for 50 years, in which the Persians left Lazistan to the Romans, and the Romans paid subsidies to Persia. Meanwhile in the east the Hephthalites had been attacked by the Turks, who now appear for the first time in history. Chosroes united with them and conquered Bactria, while he left the country north of the Oxus to the Turks. He also assisted the dynasts of Yemen to expel the Ethiopians and Yemen became dependent on Persia. In 571 a new war with Rome broke out about Armenia, in which Chosroes conquered the fortress Dara on the Euphrates, invaded Syria and Cappadocia, and returned with large booty. During the negotiations with the emperor

Tiberius, Chosroes died in 579, and was succeeded by his son Hormizd IV.

Although Chosroes had extirpated the heretical Persian sect of the Mazdakites (*see* KAVADH) he was a tolerant adherent of Zoroastrian orthodoxy. He introduced a system of taxation, based upon a survey of landed possessions begun by his father.

2. CHOSROES II., "the Victorious" (*Parvez*), 590–628, son of Hormizd IV and grandson of Chosroes I, was raised to the throne by the magnates who had rebelled against his father in 590. At the same time the general Bahram Chobin proclaimed himself king. The war with the Romans, begun in 571, had not yet ended. Chosroes fled to Syria, and persuaded the emperor Maurice (*q.v.*) to send help. Many acknowledged Chosroes, and in 591 he was brought back to Ctesiphon and Bahram Chobin beaten. Peace with Rome was then made, Maurice merely restoring the former frontier and abolishing the subsidies which had formerly been paid to the Persians. When in 602 Maurice was murdered by Phocas, Chosroes began war with Rome to avenge his death. His armies plundered Syria and Asia Minor, and in 608 advanced to Chalcedon. In 613 and 614 Damascus and Jerusalem were taken by the general Shahrbaraz, and the Holy Cross seized. Soon after, Egypt fell. The Romans could offer little resistance, as they were torn by internal dissensions, and pressed by the Avars and Slavs. At last, in 622, the emperor Heraclius (successor of Phocas in 610) was able to take the field. In 624 he advanced into northern Media, where he destroyed the great fire temple of Gandzak (Gazaca); in 626 he fought in Lazistan, while Shahrbaraz advanced to Chalcedon and tried in vain to conquer Constantinople. In 627 Heraclius defeated the Persian army at Nineveh and advanced toward Ctesiphon. Chosroes fled, and as his despotism and indolence had roused opposition, his eldest son, Kavadh II, whom he had imprisoned, was set free and proclaimed king. Four days afterward, Chosroes was murdered (Feb. 628). Meanwhile, Heraclius returned in triumph to Constantinople; in 629 the Cross was given back to him and Egypt evacuated, while the Persian empire, from the apparent greatness which it had reached ten years earlier, sank into hopeless anarchy.

See PERSIA: *Ancient History*, and the references there given. For the Roman wars *see* authorities quoted under MAURICE and HERACLIUS.

CHOTA NAGPUR, a division of British India in Bihar, consisting of five British districts, viz., Hazaribagh, Ranchi, Palamau, Manbhum and Singhbhum. Chota Nagpur consists of a hilly, forest-clad plateau, inhabited mostly by aboriginal races, between the basins of the Son, the Ganges and the Mahanadi. The total area is 27,112 sq.mi. The population in 1941 was 7,516,349. The principal agricultural products are rice, Indian corn, pulses, oilseeds and potatoes. A small quantity of tea is grown in Ranchi district. The principal jungle products are timber, lac, tussur silk and *mahuá* flowers, which are used as food and also distilled into a strong country liquor. Chota Nagpur contains the Jharia, Giridih, Bokaro, Karanpura, Ramgarh and Daltonganj coal fields. It has other valuable mineral resources. Mica is mined in Hazaribagh and iron ore in Singhbhum, where the output is already nearly 500,000 tons; there is a belt of copper ore in the latter district, where also manganese ore, gold, chromite and apatite occur; and important deposits of bauxite have been found in Ranchi and Palamau.

The indigenous inhabitants consist of non-Aryan tribes, the principal of whom are the Hos, Oraons, Santals, Mundas and Bhumij. Except in Palamau these tribes were never subdued by the Mohammedans, who contented themselves with occasional expeditions and an irregular tribute of diamonds. Until the country passed under British rule, moreover, there was very little communication between Chota Nagpur and the plains of India, with the result that the tribes have preserved to a large extent their languages, customs and primitive religions.

CHOUANS, the name given to the bands of peasants, mainly smugglers and dealers in contraband salt, who rose in revolt in the west of France, in 1793, and joined the royalists of la Vendée (*see* FRANCE: *History*). The Breton word *chouan* means "screech-owl," and is supposed to have been originally applied as a nickname to Jean Cottereau (1767–94), the leader of the revolt, and afterward extended to his followers. In any case, it was appropriate; for they were night birds and used the hoot of an owl as a signal. The motive for revolt was less devotion to the monarchy than resentment at interference of the new republican government with their old habits; the ruin of their contraband trade by the abolition of the *Gabelle* (*q.v.*); the attacks by the convention on the priesthood, and, above all, the enforcement of conscription. Their methods of warfare were barbarous and were met by barbarous reprisals. A vivid picture of these wild people is given by Honoré de Balzac in his novel *Les Chouans.*

CHOUETTE, a method whereby three or more persons may participate in a two-hand game. The three or more players establish an order of precedence, by lot or in any other way. Highest in precedence is "in the box" and plays against next highest, who is "captain." All other players bet that the captain (with whom they may consult) will win. If the man in the box wins, he collects the agreed stake from each other player individually; the captain becomes lowest in precedence. If the captain wins, he is in the box for the next game. The player previously in the box pays the agreed stake to each other player individually and becomes lowest in the order of precedence. In either case, the player who was next under the captain in precedence becomes the captain for the next game. (A. H. MD.)

CHOUGH (*Pyrrhocorax pyrrhocorax*), a bird of the crow family. It inhabits mountains and rocky coasts in Europe and North Africa. The combined effects of persecution by man and competition with the jackdaw (*q.v.*) have reduced its numbers greatly and it is now rare. Recognized by its black plumage and bright red legs and red, curved beak, the Cornish chough is more slenderly built than the crows. It is less common in Great Britain and Ireland, though a breeding resident. The Alpine chough (*P. graculus*), smaller and with a yellow bill, is gregarious. It is a European species.

CHOUTEAU, AUGUSTE (1739–1829), American pioneer, was born in New Orleans, La., in 1739. With his younger brother Pierre (1749–1849), he was the founder of the city of St. Louis, Mo. In Aug. 1763, they joined the expedition of Pierre Ligueste Laclède who had received a commission from the director-general of Louisiana to establish the fur trade in the country west of the Mississippi. In this party Auguste was given command of the boat, and in Oct. 1763, they reached the settlement of Sainte Genevieve. In the winter they ascended to a point about 60 miles upstream and chose a site on the western bank for their chief trading station, which they named St. Louis. On Feb. 15, 1764, a party under the direction of Auguste Chouteau began active trading operations. The two brothers remained in the new settlement and built up a profitable fur trade with the Indians of the north and west. Auguste died in St. Louis on Feb. 24, 1829. His son Pierre Chouteau (1789–1869), developed an immense business in furs, becoming an associate of John Jacob Astor (*q.v.*).

CHRESTIEN, FLORENT (1541–1596), French satirist and Latin poet, the son of Guillaume Chrestien, a French writer on physiology, was born at Orleans on Jan. 26, 1541. A pupil of Henri Estienne, the Hellenist, at an early age he was appointed tutor to Henry of Navarre, afterward Henry IV, who made him his librarian. Brought up as a Calvinist, he became a convert to Catholicism. He was one of the authors of the *Satyre Ménippée*, the famous pasquinade in the interest of his old pupil, Henry IV, and his works include a Latin version of *Hero and Leander* and French versions of Buchanan's *Jephthé* and Oppian's *De Venatione*. He died at Vendôme on Oct. 26, 1596.

CHRÉTIEN DE TROYES, a native of Champagne, and one of the famous French mediaeval poets. We possess very few details as to his life, and opinion differs as to the exact date to be assigned to his poems. We know that he wrote *Le Chevalier de la Charrette* at the command of Marie, countess of Champagne (the daughter of Louis VII and Eleanor of Aquitaine, married to the count of Champagne in 1164), and *Le Conte du Graal*, or *Perceval* for Philip, count of Flanders, guardian of the young king, Philip Augustus from 1180 to 1182. As Chrétien refers to the

story as the best tale told *au cort roial* it was probably composed during the regency. It was left unfinished, and later continued by three writers, Wauchier de Denain, Gerbert de Montreuil and Manessier. The second of these says definitely that Chrétien died before he could complete his poem. The extant works in their chronological order are, *Érec, Cligès, Le Chevalier de la Charrette* (*Lancelot*), *Le Chevalier au Lion* (*Yvain*) and *Le Conte du Graal* (*Perceval*) all dealing with Arthurian legend. Besides these he himself mentions a *Tristan*, and certain translations from Ovid's *Ars amatoria*, and *Metamorphoses*. A portion of this last was found by Gaston Paris, included in the translation of Ovid by Chrétien Legouais; of the *Tristan* no trace has yet been discovered. There is also a poem, *Guillaume d'Angleterre*, the authorship of which is a matter of debate. Prof. Foerster claimed it as by Chrétien, and included it in his edition of the poems, but Gaston Paris never accepted it.

Chrétien's poems enjoyed widespread favour, and of the three most popular (*Érec, Yvain* and *Perceval*) there exist old Norse translations, while the first two were admirably rendered into German by Hartmann von Aue. There is an English translation of the *Yvain, Ywain and Gawain*, and there are Welsh versions of all three stories, though their exact relation to the French is still a matter of debate. Chrétien's style is easy and graceful, he is analytic but not dramatic, in depth of thought and power of characterization he is decidedly inferior to Wolfram von Eschenbach, and as a poet he is probably to be ranked below Thomas, the author of *Tristan*, and the translator of Thomas, Gottfried von Strassburg. Much that has been claimed as characteristic of his work has been shown by M. Willmotte to be merely reproductions of literary conceits employed by his predecessors. In the words of so competent a judge as M. J. Bédier he appears to have been "not so much a creative artist as a clever compiler" and this probably represents what will be the final verdict on his work.

BIBLIOGRAPHY.—Chrétien's poems, except the *Perceval*, have been critically edited by Prof. Foerster. There is so far no edition of the *Perceval* save that printed from the Mons ms. by M. Potvin (6 vols., 1866–71, out of print and difficult to procure). Prof. Baist published a private and limited edition of ms. 794 of the *Bibl. Nationale*. Dr. Mary Williams is publishing an edition of the Gerbert continuation in the *Classiques Français du Moyen Age*. For general criticism of Chrétien's work, *see* Willmotte, *L'Évolution du roman français aux environs de 1150* (1903); also J. L. Weston, *Legend of Sir Lancelot* and *Legend of Sir Perceval* and for an appreciation, M. Borodine, *La Femme et l'amour au XIIe siècle, d'après les poèmes de Chrétien de Troyes* (1909).

CHRISM, a mixture of olive oil and balm, used for anointing in the Roman Catholic church in baptism, confirmation and ordination, and in the consecrating and blessing of churches, altars, chalices, baptismal water, etc. (through Med. Lat. *chrisma*, from Gr. χρῖσμα, an unguent). The consecration of the chrism is performed by a bishop during the High Mass on Maundy Thursday. In the Orthodox Church the chrism contains, besides olive oil, many precious spices and perfumes, and is known as "muron" or "myron." The "Chrisom," originally a head-cloth to prevent the chrism from being rubbed off a newly-baptized child's forehead, came to mean the white baptismal robe, which was used as the child's shroud if it died within the month, but was otherwise given to the church by the mother at her churching. Children dying within the month were called "chrisom-children" or "chrisoms," as in Mrs. Quickly's description of Falstaff's death (Shakespeare, *Henry V.*, ii. 3).

CHRIST, the Anointed One (Gr. Χριστός), equivalent to the Hebrew Messiah: the title given in the New Testament to Jesus of Nazareth. (*See* JESUS CHRIST; MESSIAH; CHRISTIANITY.)

CHRIST, WILHELM VON (1831–1906), German classical scholar, was born at Geisenheim, on Feb. 8, 1831, and died on Feb. 8, 1906, at Munich, where he had been professor from 1860 to 1902. His most important works are his *Geschichte der griechischen Literatur* (5th ed., 1908 f.), a history of Greek literature down to the time of Justinian, one of the best works on the subject; *Metrik der Griechen und Römer* (1879); editions of Pindar (1887); of the *Poëtica* (1878) and *Metaphysica* (1895) of Aristotle; *Iliad* (1884).

See O. Crusius, *Gedächtnisrede* (Munich, 1907).

CHRISTADELPHIANS, sometimes also called Thomasites, a community founded in 1848 by John Thomas (1805–1871), who, after studying medicine in London, migrated to Brooklyn, N.Y., U.S.A. (Χριστοῦ ἀδελφοι, "brothers of Christ"). There he at first joined the "Campbellites," but afterwards struck out independently, preaching largely upon the application of Hebrew prophecy and of the Book of Revelation to current and future events. Both in America and in Great Britain he gathered a number of adherents, and formed a community which has extended to several English-speaking countries. They believe that they alone hold the true interpretation of Scripture. Their theology is strongly millenarian, centring in the hope of a world-wide theocracy with its seat at Jerusalem. No statistics of the community are published.

See R. Roberts, *Dr. Thomas, his Life and Work* (1884); and F. J. Powicke, art. "Christadelphians" in Hastings' *Encyclopaedia of Religion and Ethics*. The community publishes a monthly magazine, *The Christadelphian*, in Birmingham.

CHRISTCHURCH, municipal borough, Southampton, England, at the confluence of the rivers Avon and Stour, 1½ mi. from the sea, and 25½ mi S.W. of Southampton on the S.R. Pop. (est. 1938) 14,050. Area 8 sq.mi. The neighbourhood was of great importance in late pre-historic times. Much of the late Bronze and early Iron age intercourse of Britain with the continent seems to have focused on Hengistbury Head and Christchurch. The town is mentioned in Saxon documents under the name of Tweotneam or Tweonaeteam, which long survived in the form Christchurch Twineham. In 901 it was seized by Aethelwald, but was recaptured by Edward the Elder. In Domesday, under the name of Thuinam, it appears as a borough belonging to the king, who held 31 messuages there. Henry I granted Christchurch (about 1100) to Richard de Redvers, who erected the castle. Only fragments remain, but the ruined Norman House apparently dates from the later part of the 12th century. The famous Augustinian priory church of the Holy Trinity is cruciform in plan, lacking a central tower but having a Perpendicular tower at the west end. The nave and transepts are principally Norman, and very fine; the choir is Perpendicular. Early English additions appear in the nave, clerestory and elsewhere, and the rood-screen is of ornate Decorated workmanship. The priory attained to such fame that its name of Christchurch finally replaced the older name of Twineham. It was dissolved in 1539.

The first charter was granted by Baldwin earl of Devon about 1150; Baldwin, the seventh earl, granted to the burgesses the tolls of the fair at St. Faith and common of pasture in certain meads shortly after 1257. The Holy Trinity fair is mentioned in 1226.

Christchurch was not incorporated till 1886. The town has never enjoyed any great prosperity, though the salmon fisheries have always been famous. It is mainly residential and is a holiday resort. There is a small harbour.

From 1571 the borough was represented in the house of commons by two members until the Reform act of 1832 reduced the number to one.

Christchurch is included in the New Forest and Christchurch division of Southampton.

CHRISTCHURCH, a city of New Zealand, near the east coast of South Island, to the north of Banks peninsula, in Selwyn county; the capital of the provincial district of Canterbury and the seat of a bishop. Pop. (1936) 92,189 (132,559 including suburbs).

Christchurch stands on the great Canterbury plain; a background is supplied by the distant mountains to the west and by the nearer hills to the south. The small river Avon winds through the city. Christchurch is chiefly dependent on the rich agricultural district which surrounds it, the plain being mainly devoted to cereals and grazing. It is also the site of a number of important industries, including particularly meat freezing and woollen manufacturing. Railways connect with Blenheim to the north and with Dunedin and Invercargill to the south, with many branches through the agricultural districts; also with Lyttelton, the port of Christchurch, 8 mi. southeast. The principal public buildings include the government offices, the museum, with its fine collection

of remains of the extinct bird, moa, and the McDougall Art gallery. There is a fine Gothic cathedral built from designs of Sir G. Gilbert Scott in Early English style, with a tower and spire 240 ft. high. Among the city's many noted educational institutions is Canterbury University college, a constituent college of the University of New Zealand. There is a Roman Catholic pro-cathedral attached to a convent of the Sacred Heart. A large extent of open ground comprises Hagley park, recreation grounds, and the Botanical gardens, which are among the largest and finest in the dominion. Wide streets cross one another for the most part at right angles, and there are well-planted parks, avenues and private gardens. The foundation of Christchurch is connected with the so-called "Canterbury Pilgrims," who settled in this district in 1850. Lyttelton was the original settlement, but Christchurch came into existence in 1851, and is thus the latest of the settlements of the original colony.

The city became a municipality in 1862. In 1903 several populous suburban boroughs were amalgamated with Christchurch.

See *City of Christchurch, New Zealand, Yearbook* (annual).

CHRISTENSEN, JENS CHRISTIAN (1856–1933), Danish politician, was born in North Jutland. The son of a peasant farmer, he was an elementary school teacher from 1877 to 1901. In 1890 he entered Parliament and eventually became leader of the Liberal party. In 1901 he was Minister of Education in the first Liberal government, and from 1905 to 1908 was Prime Minister. In 1909 he was Minister of Defence and in this capacity carried through the Army bill. From 1912 to 1913 he was Speaker of the *Folketing* (Lower House), from 1916 to 1918 minister without portfolio, and Minister of Worship from 1920 to 1922. He retired from politics in 1924. He has published a book, *Fra min Barndom og Ungdom* (1925).

CHRISTIAN II. (1481–1559), king of Denmark, Norway and Sweden, son of John (Hans) and Christina of Saxony, was born at Nyborg Castle on July 1, 1481, and succeeded his father as king of Denmark and Norway in 1513. As viceroy of Norway (1502–12) he had already displayed singular capacity. Patriotism, courage, statesmanship—these qualities were indisputably his; but unfortunately they were vitiated by obstinacy, suspicion and a sulky craftiness, beneath which simmered a very volcano of revengeful cruelty. Christian's succession to the throne was confirmed at the *Herredag* or assembly of notables from the three northern kingdoms, which met at Copenhagen in 1513. A decision as to the Swedish succession was postponed, as the Swedish delegates refused to accept Christian as king. On June 11, 1514, he was crowned king of Denmark and Norway at Copenhagen, and on the same day he married, by proxy, Isabella, sister of the future emperor Charles V. The wedding was celebrated on Aug. 12, 1515. But he would not give up his liaison with Dyveke, a Dutch girl of bourgeois origin, and on the death of the unfortunate girl in 1517, under suspicious circumstances, Christian revenged himself by executing the magnate Torben Oxe, who was supposed to have been Dyveke's murderer, despite the strenuous opposition of Oxe's fellow peers; henceforth the king lost no opportunity of depressing the nobility and raising plebeians to power. His chief counsellor was Dyveke's mother Sigbrit, a born administrator and a commercial genius of the first order. Christian first appointed her controller of the Sound tolls, and ultimately committed to her the whole charge of the finances. A *bourgeoise* herself, Sigbrit soon became the soul of a middle-class inner council, which competed with the *Rigsraad* itself. The patricians naturally resented their supersession and nearly every unpopular measure was attributed to the influence of "the foul-mouthed Dutch sorceress who hath bewitched the king."

Meanwhile Christian was preparing for the inevitable war with Sweden, where the Patriotic Party, headed by the freely elected governor Sten Sture the younger, stood face to face with the philo-Danish Party under Archbishop Gustavus Trolle. Christian, who had already taken measures to isolate Sweden politically, hastened to the relief of the archbishop, who was beleaguered in his fortress of Stäke, but was defeated by Sture and his peasant levies at Vedla and forced to return to Denmark, while the castle was destroyed and the archbishop deposed and imprisoned. A second attempt to subdue Sweden in 1518 was also frustrated by Sture's victory at Bränkyrka. A third attempt made in 1520 with a large army of French, German and Scottish mercenaries proved successful. Christian had persuaded Pope Leo X. to excommunicate Sture and to lay Sweden under an interdict. Sture was defeated at Bogesund and mortally wounded at the battle of Tiveden, on Jan. 19, and the Danish army, unopposed, was approaching Uppsala, where the members of the Swedish *Riksråd* had already assembled. The senators consented to render homage to Christian on condition that he gave a full indemnity for the past and a guarantee that Sweden should be ruled according to Swedish laws and custom; and a convention to this effect was confirmed by the king and the Danish *Rigsraad* on March 31. But Sture's widow, Dame Christina Gyllenstjerna, still held out stoutly at Stockholm, and the peasantry of central Sweden, stimulated by her patriotism, flew to arms, defeated the Danish invaders at Balundsäs (March 19) and were only with the utmost difficulty finally defeated at the bloody battle of Uppsala (Good Friday, April 6). In May the Danish fleet arrived, and Stockholm was invested by land and sea on Sept. 7. Christina surrendered on the promise of a general amnesty. On Nov. 1, the representatives of the nation swore fealty to Christian as hereditary king of Sweden, and on Nov. 4 he was crowned by Gustavus Trolle in Stockholm cathedral. The next three days were given up to banqueting, but on Nov. 7 "an entertainment of another sort began." On the evening of that day a band of Danish soldiers broke into the great hall and carried off several carefully selected persons. By 10 o'clock the same evening the remainder of the king's guests were safely under lock and key. All these persons were charged with heresy and violence against the church by archbishop Trolle, who presided over their trial on the following day. At 12 o'clock on the night of Nov. 8 the patriotic bishops of Skara and Strängnäs were led out into the great square and beheaded. The executions, known as the "Stockholm bath of blood," continued throughout the following day; in all, about 82 people, most of them noblemen, were thus murdered. Sten Sture's body was dug up and burnt, as well as the body of his little child. Dame Christina and many other noble Swedish ladies were sent as prisoners to Denmark. Christian suppressed his political opponents under the pretence of defending an ecclesiastical system which in his heart he despised.

With his brain teeming with great designs Christian II. returned to his native kingdom. Deeply distrusting the Danish nobles with whom he shared his powers, he sought helpers from among the wealthy middle classes of Flanders. In June 1521 he paid a sudden visit to the Low Countries, and remained there for some months. He visited most of the large cities, took into his service many Flemish artisans, and made the personal acquaintance of Quentin Matsys and Albrecht Dürer, the latter of whom painted his portrait. Christian also entertained Erasmus, with whom he discussed the Reformation, and let fall the characteristic expression: "Mild measures are of no use; the remedies that give the whole body a good shaking are the best and surest." On his return to Denmark on Sept. 5, 1521, Christian proceeded at once to inaugurate the most sweeping reforms. Soon after his return, in 1521 and 1522, he issued his great *Landelove*, or Code of Laws. For the most part this is founded on Dutch models, and testifies in a high degree to the king's progressive aims. Provision was made for the better education of the lower, and the restriction of the political influence of the higher clergy; there were stern prohibitions against wreckers and "the evil and unchristian practice of selling peasants as if they were brute beasts"; the old trade guilds were retained, but the rules of admittance thereto made easier, and trade combinations of the richer burghers, to the detriment of the smaller tradesmen, were sternly forbidden. Unfortunately these reforms, excellent in themselves, suggested the standpoint not of an elected ruler, but of a monarch by right divine. Some of them were even in direct contravention of the charter; and the old Scandinavian spirit of independence was deeply wounded by the preference given to the Dutch.

Sweden too was now in open revolt; and both Norway and

Denmark were taxed to the uttermost to raise an army for the subjection of the sister kingdom. In Jan. 1521 a young Swedish noble, Gustave Eriksson Vasa, at the head of a small force of dalesmen, led a revolt against Christian. (For the ensuing struggle which terminated the union between Denmark and Norway, *see* GUSTAVUS I. ERIKSSON and SWEDEN: *History*.) On June 6, 1523, Gustavus Eriksson was elected king of Sweden. Foreign complications were added to these domestic troubles. With the laudable object of releasing Danish trade from the grinding yoke of the Hansa, and making Copenhagen the great emporium of the north, Christian had arbitrarily raised the Sound tolls and seized a number of Dutch ships which presumed to evade the tax. Thus his relations with the Netherlands were strained, while with Lübeck and her allies he was openly at war. Finally Jutland rose against him late in 1522, renounced its allegiance and offered the Danish crown to Duke Frederick of Holstein (Jan. 20, 1523). So overwhelming did Christian's difficulties appear that he took ship to seek help abroad, and on May 1 landed at Veere in Zealand. Eight years later (Nov. 1531) he attempted to recover his kingdoms, and obtained some support from Olaf, archbishop of Trondhjem, who feared for the safety of the church under Frederick's rule. Christian landed with a small army of Dutch mercenaries on the Norwegian coast and proclaimed himself king at Oslo (Nov. 29). But he wasted time and opportunities; his fleet was destroyed by a Danish force, and it was arranged that he should negotiate with Frederick in person, on the understanding that if the negotiations broke down he should be allowed to return to Norway. When he reached Denmark, however, he was thrown into prison, first in Sonderborg Castle, afterwards in Kalundborg Castle. He died in Jan. 1559.

See K. P. Arnoldson, *Nordens enhet och Kristian II.* (Stockholm, 1899); Paul Frederik Barfod, *Danmarks Historie fra 1319 til 1536* (1885); *Danmarks Riges Historie*, vol. 3 (1897–1905); R. N. Bain, *Scandinavia*, chap. 2 (Cambridge, 1905). (R. N. B.; X.)

CHRISTIAN III. (1503–1559), king of Denmark and Norway, was the eldest son of Frederick I. of Denmark and his first consort, Anne of Brandenburg. Educated by German Lutheran teachers, Christian travelled in Germany in 1521 and was present at the Diet of Worms. On his return he found that his father had been elected king of Denmark in place of Christian II. Christian's unconcealed Lutheran views brought him into collision with the Catholic *Rigsraad*, and the religious intolerance which he showed in his capacity of stadtholder of the Duchies in 1526, and as viceroy of Norway in 1529, greatly provoked the Catholic party. On the death of Frederick I. in 1533 confusion arose over the election of his successor. Christian was supported by the nobility of Denmark; a strong Catholic party wished to put his younger brother, Hans, who was a child and still a Catholic, on the throne; while the peasants and burghers hoped for the restoration of the captive Christian II. (*q.v.*), and allied themselves with the citizens of Lübeck, who were led by Count Christopher of Oldenburg. Duke Christian crushed the rising of the peasants, made peace with Lübeck and in March 1535 was proclaimed king of Denmark at Viborg.

Christian III.'s triumph brought about the fall of Catholicism. On Aug. 12, 1536, the archbishop and bishops were arrested; on Oct. 30 a national assembly abolished episcopacy, made over the episcopal property to the Crown and established the Lutheran Church in Denmark, with the king as its head. The royal charter issued the same day proclaimed the Crown of Denmark, hitherto elective, hereditary in Christian's line.

The first six years of Christian's reign in Denmark were marked by a contest between the Danish *Rigsraad* and the German counsellors, both of whom sought to rule "the pious king" exclusively. Though the Danish party won a signal victory at the outset, by obtaining the insertion in the charter of provisions stipulating that only native-born Danes should fill the highest dignities of the State, the king's German counsellors continued paramount during the earlier years of his reign. The ultimate triumph of the Danish party dates from 1539, the dangers threatening Christian III. from the emperor Charles V., and other kinsmen of the imprisoned Christian II., compelling him to lean exclusively on Danish magnates and soldiers. The complete identification of the Danish king with the Danish people was accomplished at the *Herredag* of Copenhagen, 1542, when the nobility of Denmark voted Christian a twentieth part of all their property to pay off his heavy debt to the Holsteiners and Germans.

The pivot of the foreign policy of Christian III. was his alliance with the German Evangelical princes, as a counterpoise to the persistent hostility of Charles V., who was determined to support the hereditary claims of his nieces, the daughters of Christian II., to the Scandinavian kingdoms. War was actually declared against Charles V. in 1542, and though the German Protestant princes proved faithless allies, the closing of the Sound against Dutch shipping proved such an effective weapon in King Christian's hand that the Netherlands compelled Charles V. to make peace with Denmark at the Diet of Spires on May 23, 1544. The foreign policy of Christian's later days was regulated by the Peace of Spires. He carefully avoided all foreign complications; refused to participate in the Schmalkaldic War of 1546; mediated between the emperor and Saxony after the fall of Maurice of Saxony at the battle of Sievershausen in 1553, and contributed essentially to the conclusion of peace. King Christian III. died on New Year's day, 1559. Though not, perhaps, a great, he was, in the fullest sense of the word, a good ruler. A strong sense of duty, genuine piety and a cautious, but by no means pusillanimous common-sense, coloured every action of his patient, laborious and eventful life. He found Denmark in ruins; he left her stronger and wealthier than she had ever been before.

See *Danmarks Riges Historie*, vol. iii. (Copenhagen, 1897–1901); Huitfeld, *King Christian III.'s Historie* (Copenhagen, 1595); R. N. Bain, *Scandinavia*, ch. iv., v. (Cambridge, 1905).

CHRISTIAN IV. (1577–1648), king of Denmark and Norway, the son of Frederick II., king of Denmark, and Sophia of Mecklenburg, was born at Fredriksborg castle on April 12, 1577, and succeeded to the throne on the death of his father (April 4, 1588); during his minority which lasted till Aug. 17, 1596, the government was carried on by a regency of four. The young king's court was one of the most joyous and magnificent in Europe; yet he found time for work of the most various description, including a series of domestic reforms (*see* DENMARK: *History*). New fortresses were constructed under the direction of Dutch engineers. The Danish navy was developed and improved. In the war with Sweden, generally known as the "Kalmar War" (*see* SWEDEN: *History*), Christian compelled Gustavus Adolphus to give way on all essential points (treaty of Knäred, Jan. 20, 1613). After this war Christian made efforts to improve the army, which was composed mainly of mercenaries, though it was not until after the Thirty Years' War that any effective reforms were carried through. He then turned his attention to Germany. His object was twofold: first, to obtain the control of the great German rivers, the Elbe and the Weser; secondly, to acquire the secularized German bishoprics of Bremen and Werden as appanages for his younger sons. He skilfully took advantage of the alarm of the German Protestants after the battle of White Hill in 1620, to secure the coadjutorship to the see of Bremen for his son Frederick (Sept. 1621), a step followed in November by a similar arrangement as to Werden; while Hamburg by the compact of Steinburg (July 1621) was induced to acknowledge the Danish overlordship of Holstein. The growing ascendancy of the Catholics in North Germany in and after 1623 almost induced Christian, for purely political reasons, to intervene directly in the Thirty Years' War. The solicitations of the Western Powers led him in 1625 to plunge into war against the combined forces of the emperor and the League. For this defeat at Lutteram-Barenberge and the invasion of Jutland by Tilly and Wallenstein *see* THIRTY YEARS' WAR. In his extremity Christian now formed an alliance with Sweden (Jan. 1, 1628), whereby Gustavus Adolphus pledged himself to assist Denmark with a fleet in case of need, and shortly afterwards a Swedo-Danish army and fleet compelled Wallenstein to raise the siege of Stralsund. Declining to form a further alliance with Sweden for the defence of the North, and of Protestantism, Christian concluded a separate peace on May 12, 1629 with the emperor at Lübeck, without any

diminution of territory, at the price of abandonment of the Protestant cause. Unfortunately Christian would neither conciliate Sweden, henceforth his most dangerous enemy, nor guard himself against her by a definite system of counter-alliances. By mediating in favour of the emperor, after the death of Gustavus Adolphus in 1632, he tried to minimize the influence of Sweden in Germany, and his whole Scandinavian policy was so irritating and vexatious that Swedish statesmen made up their minds to wage war with Denmark. In May 1643 the Swedish *Riksråd* decided upon war; on Dec. 12 the Swedish marshal Lennart Torstensson, advancing from Bohemia, crossed the northern frontier of Denmark; by the end of Jan. 1644 the whole peninsula of Jutland was in his possession. This totally unexpected attack, conducted from first to last with consummate ability and lightning-like rapidity, had a paralysing effect upon Denmark. Yet in his sixty-seventh year Christian IV. once more displayed something of the magnificent energy of his triumphant youth. Night and day he laboured to levy armies and equip fleets. Fortunately too for him, the Swedish government delayed hostilities in Scania till Feb. 1644, so that the Danes were able to make adequate defensive preparations and save the important fortress of Malmö. Torstensson was unable to cross from Jutland to Fünen for want of a fleet, and the Dutch auxiliary fleet which came to his assistance was defeated between the islands of Sylt and Rönnö on the west coast of Schleswig by the Danish admirals. Another attempt to transport Torstensson and his army to the Danish islands by a large Swedish fleet under Klas Fleming was frustrated by Christian IV. in person on July 1, 1644. On that day the two fleets encountered off Kolberg Heath, S.E. of Kiel Bay, and Christian displayed a heroism which endeared him ever after to the Danish nation. Darkness at last separated the fleets; and though the battle was a drawn one, the Danish fleet showed its superiority by blockading the Swedish ships in Kiel Bay. But the Swedish fleet escaped, and the annihilation of the Danish fleet by the combined navies of Sweden and Holland at the end of September exhausted the military resources of Denmark and compelled Christian to accept the mediation of France and the United Provinces. Peace was finally signed at Brömsebro in 1645. (*See* DENMARK: *History*.)

The last years of the king were still further embittered by struggles with the nobility to whom he was forced to concede more and more power. He died at Copenhagen in Feb. 1648. During his reign Norway made great strides in economic and administrative prosperity under his son-in-law, Hannibal Sehested (*q.v.*), as Stadtholder. (*See* NORWAY: *History*.)

CHRISTIAN V. (1646–1699), king of Denmark and Norway, the son of Frederick III. of Denmark and Sophia Amalia of Brunswick-Lüneburg, was born on April 15, 1646, at Flensburg, and succeeded to the throne on Feb. 9, 1670. Christian was very popular among the lower orders, but hated the old noble families, and tried to establish a new nobility by creating two new orders, consisting largely of officials and upper middle class families, which were to take precedence of the older ones. Under the guidance of his great chancellor Griffenfeldt (*q.v.*), Christian carried his ideas of absolute government into practice, introducing extreme centralization into the organization of civil and military affairs. Griffenfeldt pursued an ambitious policy of foreign alliances, but aimed at keeping peace, and for a brief period Denmark seemed to have a chance of regaining her position as a great power; but Christian sacrificed Griffenfeldt to the jealousy of his adversaries, and sentenced him to life-long imprisonment. After this the financial position of the state grew steadily worse, owing partly to the extravagance of the court, partly to the unremunerative war with Sweden (1675–79). Christian was a weak despot, though his personal courage and affability made him popular among the lower orders. During his reign a new code of laws was drawn up for Norway, begun in 1661 and completed in 1683. He died in a hunting accident on Aug. 25, 1699.

See P. E. Holm, *Danmarks indre Historie under Enevaelden* (Copenhagen, 1881–86); A. D. Jörgensen, *Peter Griffenfeldt* (Copenhagen, 1893); R. N. Bain, *Scandinavia* cap. x., xi. (Cambridge, 1905).

CHRISTIAN VII. (1749–1808), king of Denmark and Norway, was the son of Frederick V., king of Denmark, and his first consort Louise, daughter of George II. of Great Britain. He became king on his father's death on Jan. 14, 1766. Badly educated, systematically terrorized by a brutal governor and hopelessly debauched by corrupt pages he grew up a semi-idiot. After his marriage in 1766 with Caroline Matilda (1751–1775), daughter of Frederick, prince of Wales, he abandoned himself to the worst excesses. He ultimately sank into a condition of mental stupor and became the obedient slave of the upstart Struensee (*q.v.*) who, after the dismissal of Bernstorff in 1770, controlled all affairs of State. After the fall of Struensee (the warrant for whose arrest he signed with indifference) in 1772, for the last 26 years of his reign, he was only nominally king, his half-brother, Prince Frederick, acting as regent. He died on March 13, 1808. In 1772 the king's marriage with Caroline Matilda, who had been seized and had confessed to criminal familiarity with Struensee, was dissolved, and the queen, retaining her title, passed her remaining days at Celle in Hanover, where she died on May 10, 1775.

See E. S. F. Reverdil, *Struensee et la cour de Copenhague, 1760–1772* (1858); *Danmarks Riges Historie*, vol. v. (Copenhagen, 1897–1905); and for Caroline Matilda, Sir F. C. L. Wraxall, *Life and Times of Queen Caroline Matilda* (1864), and W. H. Wilkins, *A Queen of Tears* (1904).

CHRISTIAN VIII. (1786–1848), king of Denmark and Norway, the only son of Frederick (d. 1805, half brother to Christian VII and son of Frederick V), was born on Sept. 18, 1786, at Christiansborg castle. His first marriage with his cousin Charlotte Frederica of Mecklenburg-Schwerin was dissolved in 1810. In May 1813 he was sent as stadtholder to Norway to promote the loyalty of the Northmen to the dynasty, which had been very rudely shaken by the disastrous results of Frederick VI.'s adhesion to the falling fortunes of Napoleon. Though his endeavours were opposed by the so-called Swedish party in Norway, which desired a dynastic union with Sweden, he was elected regent of Norway by an assembly of notables on Feb. 16, 1814. This election was confirmed by a *Storthing* held at Eidsvold on April 10 and on May 17 Christian was elected king of Norway. On being summoned by the commissioners of the allied powers at Copenhagen to bring about a union between Norway and Sweden in accordance with the terms of the treaty of Kiel, he replied that, as a constitutional king, he could do nothing without the consent of the *Storthing*, to the convocation of which a suspension of hostilities on the part of Sweden was the condition precedent. A short campaign ensued, in which Christian was easily worsted by the superior skill and forces of the Swedish crown prince (Bernadotte). The brief war was finally concluded by the convention of Moss on Aug. 14, 1814 (*see* NORWAY: *History*). Henceforth Christian's alleged democratic principles made him suspect, and he and his second wife, Caroline Amelia of Augustenburg, whom he married in 1815, lived in comparative retirement. It was not till 1831 that old King Frederick gave him a seat in the council of state. On Dec. 13, 1839 he ascended the Danish throne as Christian VIII. The Liberal party had high hopes of "the giver of constitutions," but he disappointed his admirers by steadily rejecting every Liberal project. He came into conflict with the German element in the duchies of Schleswig and Holstein by issuing (March, 1844) a patent permitting, under certain circumstances, the use of the Danish language in the estates. By his Open Letter of July 8, 1846, in which he declared that the *Kongelov*, Danish royal law in the matter of the succession applied to Schleswig and Lauenburg, though its application to parts of Holstein was doubtful, and by the Constitution of Jan. 28, 1848, he raised the Schleswig-Holstein question in a form which involved his successor in the War of 1848. (*See* SCHLESWIG-HOLSTEIN QUESTION.) He died at Plön on Jan. 20, 1848.

See Just Matthias Thiele, *Christian den Ottende* (Copenhagen, 1848); Yngvar Nielsen, *Bidrag til Norges Historie* (Christiania, 1882–86). A. J. Lange, *Christian Frederik som Norges Statholder regent og Konge* (1914).

CHRISTIAN IX (1818–1906), king of Denmark, was a younger son of William, duke of Schleswig-Holstein-Sonderburg-Glücksburg (d. 1831), a direct descendant of the Danish king Christian III by his wife Louise, a daughter of Charles, prince of Hesse-Cassel (d. 1836), and grand-daughter of King Frederick V. Born at Gottorp on April 8, 1818, Christian entered the army, and served with the Danish troops in Schleswig during the insurrection of 1848. In 1842 he married Louise (1817–1898), daughter of William, prince of Hesse-Cassel (d. 1867), and cousin of King Frederick VII. The reigning king, Frederick VII, being childless, the representatives of the great powers met in London and settled the crown on Prince Christian (May 1852), an arrangement confirmed in Denmark in 1853. The "protocol king," as Christian was sometimes called, ascended the throne on Frederick's death in Nov. 1863. By putting into force (Nov. 18) the recently drafted constitution under which Schleswig was to be incorporated with Denmark, he came into conflict with the German confederation. (*See* SCHLESWIG-HOLSTEIN QUESTION.) The German-Danish War followed, which ended by the separation (Oct. 13, 1864) of the duchies from Denmark. Within the narrowed limits of his kingdom Christian's difficulties were more protracted and hardly less serious. During almost the whole of his reign the Danes were engaged in a political struggle between the "Right" and the "Left," the former being supported in general by the *Landsting*, and the latter by the *Folketing*. The king was for many years successful in preventing the radicals from coming into office, but in 1901 he was forced to assent to the formation of a "cabinet of the Left" (*see* DENMARK: *History*). In his later years he occupied a patriarchal position among the sovereigns of Europe to many of whom he was related. His eldest son Frederick had married a daughter of Charles XV of Sweden; his second son George had been king of the Hellenes since 1863; his youngest Waldemar (1858–1939) was married to Marie d'Orléans, daughter of Robert, duc de Chartres. Of his three daughters, Alexandra married Edward VII of Great Britain; Dagmar (Marie Feodorovna), the tsar Alexander III; and Thyra, Ernest Augustus, duke of Cumberland. One of his grandsons, Charles, who married Princess Maud of England, became king of Norway as Haakon VII in 1905, and another, Constantine, crown prince (afterwards king) of Greece, married a sister of the German emperor William II. Christian was also the ruler of Iceland. He died at Copenhagen on Jan. 29, 1906, and was buried at Roskilde.

See Barfod, *Kong Kristian IX's Regerings-Dagbog* (Copenhagen, 1876); and *Hans Majestet Kong Kristian IX* (Copenhagen, 1888).

CHRISTIAN X, king of Denmark and Iceland (1870–1947), was born on Sept. 26, 1870, at Charlottenlund castle, near Copenhagen, the eldest son of Crown Prince Frederick, later King Frederick VIII (1906–12), and Louise, princess of Sweden and Norway. After matriculating in 1889, the prince embarked upon a military career, becoming chief of the royal guard, and attained the rank of major general. He married, in 1898, Alexandrine, duchess of Mecklenburg-Schwerin and they had two sons, Crown Prince Frederick (b. 1899) and Prince Knud (b. 1900). In 1906 he became crown prince and in 1912 ascended the throne.

During World War I the necessity of friendly intercourse between the Scandinavian kingdoms resulted in several meetings among the three kings, of which the first was held at Malmö in Dec. 1914. On June 5, 1915, King Christian signed the new constitution of Denmark which extended the franchise to women. He signed, on Dec. 1, 1919, the Federal act, whereby Denmark acknowledged Iceland as an independent kingdom and king of Iceland was incorporated in the king's title. In 1944, however, Iceland completely severed its ties with Denmark. In July 1920 he rode over the old frontier into Slesvig Nord, which had been ceded to Denmark by the Treaty of Versailles, and received an enthusiastic reception from the people. When the Germans occupied Denmark in 1940, King Christian retained control of the internal organization of the country, and endeared himself to his people by his "passive resistance." During October of 1942 he became ill with pneumonia after a fall from his horse, and the crown prince was named regent temporarily. After his recovery he continued to withstand nazi pressure, although he was compelled to make a speech in May 1943 warning his people against the growing sabotage of munitions and railways. Open rebellion against the occupation forces broke out in Aug. 1943, and King Christian was made a virtual prisoner at Sorgenfri castle and later at the palace of Amalienborg in Copenhagen. He opened the free Danish parliament on May 9, 1945, after the surrender of the German forces. He died at Amalienborg castle on April 20, 1947.

CHRISTIAN, WILLIAM (1608–1663), Manx politician, a son of Ewan Christian, one of the Manx deemsters, was born on April 14, 1608, and was known as *Illiam Dhone*, or Brown William. In 1648 the lord of the Isle of Man, James Stanley, 7th earl of Derby, appointed Christian his receiver-general; and when in 1651 the earl crossed to England to fight for Charles II he left him in command of the island militia. Derby was taken prisoner at the battle of Worcester, and his famous countess Charlotte de la Tremouille, who was residing in Man, sought to obtain her husband's release by negotiating with the victorious parliamentarians for the surrender of the island. At once a revolt headed by Christian broke out, partly as a consequence of this step, partly owing to the discontent caused by some agrarian arrangements recently introduced by the earl. The rebels seized many of the forts; then Christian in his turn entered into negotiations with the parliamentarians; and probably owing to his connivance the island was soon in the power of Col. Robert Duckenfield, who had brought the parliamentary fleet to Man in Oct. 1651. The countess of Derby was compelled to surrender her two fortresses, Castle Rushen and Peel castle, while Christian remained receiver-general, becoming governor of the island in 1656. Two years later, however, he was accused of misappropriating some money; he fled to England, and in 1660 was arrested in London. Having undergone a year's imprisonment he returned to Man, hoping that his offense against the earl of Derby would be condoned under the Act of Indemnity of 1661; but, anxious to punish his conduct, Charles, the new earl of Derby, ordered his seizure; he refused to plead, and a packed house of keys declared that in this case his life and property were at the mercy of the lord of the island. The deemsters then passed sentence, and in accordance therewith Christian was shot on Jan. 2, 1663. This arbitrary act angered Charles II and his advisers; the deemsters and others were punished, and some reparation was made to Christian's family. Christian is chiefly celebrated through the Manx ballad *Baase Illiam Dhone*, which was translated into English by George Borrow, and through the reference to him in Sir Walter Scott's *Peveril of the Peak*.

See A. W. Moore, *History of the Isle of Man* (1900).

CHRISTIAN CATHOLIC CHURCH, the name assumed by a religious organization founded at Zion (*q.v.*) city near Chicago, Ill., in 1896, by John Alexander Dowie (*q.v.*). Its members added to the usual tenets of Christianity a special belief in faith healing, and laid much stress on united consecration services and the threefold immersion of believers. To assist Dowie, assistant overseers were appointed, and the operations of the community included religious, educational and commercial departments. After 1903 considerable dissension arose among Dowie's followers: he was deposed in 1906; and after his death in 1907 his assistant Wilbur Glenn Voliva became general overseer of the organization.

See art. "Enthusiasts (religious)," by G. H. Gray and W. T. Whitley in Hastings, *Encyclopaedia of Religion and Ethics*, vol. v, p. 320; and K. Harlan, *John Alexander Dowie and the Christian Catholic Church*, Evansville, Wisconsin, 1906.

CHRISTIAN ENDEAVOUR SOCIETIES, organizations

(*q.v.*) formed a Young People's Society of Christian [illegible] in his (Congregational) church at Portland, Maine, U.S.A. The idea was taken up elsewhere in America and spread to other countries, till, under the presidency of Dr. Clark, a huge number of affiliated societies came into operation throughout the world. They take as their motto "For Christ and the Church," and have done much, especially in the nonepiscopal churches, to prepare

young men and women for active services in the Church. The organization is international and interdenominational, a World's Christian Endeavour Union being formed in 1895.

See Francis E. Clark, art. "Christian Endeavour," in Hastings' *Encyclopaedia of Religion and Ethics*, vol. iii. 571 ff. (with reff.) and *Memories of Many Men in Many Lands* (1922); J. R. Fleming, *The Christian Endeavour of the Future* (1903).

CHRISTIANIA, the capital of Norway; *see* OSLO.

CHRISTIANITY, regarded historically as one of the great religions of the world, owes its rise to Jesus of Nazareth, in ancient Galilee (*see* JESUS CHRIST). By reverent disciples His ancestry was traced to the royal family of David and His birth is ascribed by the church to the miraculous act of God. At 30 years of age Jesus Christ appeared in public, and after a short period (we cannot determine how long, but possibly 18 months) he was crucified, upon the accusation of His countrymen, by the Roman authorities.

Relation to Judaism.—His career is understood only in the light of His relation to Judaism (*see* JUDAISM). This faith, in a peculiarly vivid fashion, illustrates the growth and development of religion, for its great teachers in the highest degree possessed what the Germans call God-consciousness. When the national independence of Israel was destroyed, the prophetic teaching held the people together in the hope of a re-establishment of the Kingdom when all nations should be subject to it and blessed in its everlasting reign of righteousness and peace (Isa. xlix., lx.).

Some of the prophets associated the restoration of the Kingdom with the coming of the Messiah, the anointed one, who should re-establish the line of David (Isa. ix. 6 f., xi. 1 f.; Micah v. 2; Ezek. xxxiv. 23, xxxvii. 24; Zech. ix. 9; Ps. ii. 72). Others said nothing of such a one, but seemed to expect the regeneration of Israel through the labours, sufferings and triumphs of the righteous remnant (Isa. liii., Ezek. xxxvi.–xxxvii.). By the strong emphasis upon righteousness, the tribal Lord of Israel was revealed as the universal God, of one relationship to all men. This monotheism was not primarily cosmological nor metaphysical, but ethical. The Jews showed little capacity for abstract reasoning and never pursued their inquiries to the discovery of ultimate principles. Thus they did not develop a systematic cosmology, nor formulate a system of metaphysics. Their religion was pre-eminently "theocratic"; God was thought of as King, enthroned in heaven and supreme

But the prophetic teaching was obscured in part by the nationalism of the prophets themselves, who exalted Israel as at once God's instrument and the peculiar object of His love. Inevitably the freedom, spirituality and universality of the prophetic teaching were obscured. In the 1st century A.D. the national and priestly elements were supreme. The triumph of Israel was to be accomplished by the miraculous power of a Messiah who should descend out of heaven. His coming was delayed, in part by the opposition of demons, in part by the failure of the people to obey the law, which embraced both moral and ceremonial elements derived from varied sources, but by the people was all alike regarded as of divine origin. It was to be obeyed without question and without inquiry as to its meaning because established by God; it was contained in the Sacred Scriptures (*see* BIBLE: *Old Testament*), which had been revealed by God supernaturally, and its meaning was set forth by schools of learned men whose interpretations were authoritative. The priesthood held still the ancient ideas. Salvation was for the nation, and the individual was not necessarily participant in it; life after death was disbelieved or held as the existence of shades; there could be no resurrection of the body and no immortality (in the Greek sense); and with these beliefs were associated a certain worldliness and want of fervour. The more actively and aggressively religious party, on the other hand, adopted the belief in the resurrection of the body, and in the individual's participation in the Messiah's kingdom; all the pious would have their share in it, while the wicked would be outcast. But these doctrines were variously conceived. By some the Messianic kingdom was thought of as permanent, by others as intermediary, the external kingdom being transcendent. So too some thought of a literal resurrection of the body of flesh and blood, while others thought that it would be transformed. The rudiments of some of these ideas can be found in the prophets, but their development took place after the exile, and indeed for the most part after the conclusion of the writings accounted canonical. Thus too the belief in a kingdom of demons held a large place in the mind of the people, though the references to such evil beings are almost absent from the sacred writings of the Old Testament. Again it is to the East that we must look for the origin of these ideas.

The Teaching of Jesus.—Jesus completed the prophetic teachings. He employed the old phraseology and imagery, but He was conscious that He used them in a new sense, and that He preached a new gospel of great joy. Jesus was not a historian, a critic or a theologian. He used the words of common men in the sense in which common men understood them; He did not employ the Old Testament as now reconstructed by scholarship or judged by criticism, but in its simple and obvious and traditional sense, and His background is the intellectual and religious thinking of His time. The ideas of demons and of the future, of the Bible and many other traditional conceptions, are taken over without criticism. So the idea of God which He sets forth is not that of a theologian or a metaphysician, but that of the unlearned man which even the child could understand. Yet though thus speaking in untechnical language, He revolutionized His terms and filled them with new meaning. His emphasis is His own, and the traditional material affords merely the setting for His thought. He was not concerned with speculative questions about God, nor with abstract theories of His relationship to the soul and to the world. God's continual presence, His fatherly love, His transcendent righteousness, His mercy, His goodness, were the facts of immediate experience; not in proofs by formal logic but in the reality of consciousness was the certainty of God. Thus religion was freed from all particular and national elements in the simplest way: for Jesus did not denounce these elements, nor argue against them, nor did He seek converts outside Israel, but He set forth communion with God as the most certain fact of man's experience and as simple reality made it accessible to everyone. Thus His teaching contains the note of universality—not in terms and proclamations but as plain matter of fact. His way for others to this reality is likewise plain and level to the comprehension of the unlearned and of children.

For Him repentance (change of mind, μετάνοια) is placed first. The intricacies of ritual and theology are ignored, and ancient laws which contradict the fundamental beliefs are unhesitatingly abrogated or denied. He seizes upon the most spiritual passages of the prophets, and revives and deepens them; He sums up His teaching in supreme love to God and a love for fellow-man like that we hold for ourselves (Mark xii. 29–31). This supreme love to God is a complete oneness with Him in will, a will which is expressed in service to our fellow-men in the simplest and most natural relationship (Luke x. 25–37). Thus religion is ethical through and through, as God's inner nature, expressed in forgiveness, mercy, righteousness and truth, is not something transcendental, but belongs to the realm of daily life. We become children of God and He our Father in virtue of a moral likeness (Matt. v. 43–48), while of any metaphysical or (so to speak) physical relationship to God, Jesus says nothing. With this clearly understood, man is to live in implicit trust in the divine love, power, knowledge and forgiveness. Hence he attains salvation, being delivered from sin and fear and death, for the divine attributes are not ontological entities to be discussed and defined in the schools, but they are realities, entering into the practical daily life. Indeed they are to be repeated in us also, so that we are to forgive our brethren as we ask to be forgiven (Matt. vi. 12; Luke xi. 4).

As religion thus becomes thoroughly ethical, so is the notion of the Messianic kingdom transformed. Its essential characteristic is the doing of the Father's will on earth as in heaven. Jesus uses parable after parable to establish its meaning. It is a seed cast into the ground which grows and prospers (Matt. xiii. 31–32); it is a seed sown in good ground and bringing forth

fruit, or in bad ground and fruitless (Luke viii. 5–8; Mark iv. 1–32); it is a pearl of great price for which a man should sell all that he possesses (Matt. xiii. 44–46); it is not come "with observation," so that men shall say "lo here and lo there" (Luke xvii. 20–21); it is not of this world, and does not possess the characteristics or the glory of the kingdom of the earth (Luke xxii. 24–26; Mark x. 13–16); it is already present among men (Luke xvii. 21). Together with these statements in our sources are still mingled fragments of the more ordinary cataclysmic, apocalyptic conceptions, which in spite of much ingenious exegesis, cannot be brought into harmony with Christ's predominant teaching, but remain as foreign elements in the words of the Master, possibly brought back through His disciples, or, more probably, used by Jesus uncritically—a part of the current religious imagery in which He shared.

Originality.—It is often declared that in these teachings there is nothing new, and indeed analogies can be found for many sayings; yet nowhere else do we gain so strong an impression of originality. The net result is not only new but revolutionary; so was it understood by the Pharisees. They and Jesus spoke indeed the same words and appealed to the same authorities, but they rightly saw in Him a revolutionist who threatened the existence of their most cherished hopes. The Messianic kingdom which they sought was opposed point by point to the kingdom of which He spoke, and their God and His Father—though called by the same sacred name—were different. Hence almost from the beginning of His public ministry they constantly opposed Him, the conflict deepening into complete antagonism.

Jesus Christ has been termed unique, one of the common people yet separated from them, and this description applies to the breadth, depth and reality of His sympathy. In the meagre records of His life there is evidence that He deemed no form of suffering humanity foreign to Himself. This was not a mere sentiment, nor was His sympathy superficial, for it constituted the essential characteristic of His personality—"He went about doing good." In Him the will of the Father for the redemption of the race was incarnate. This led Him into the society of those outcasts who were condemned and rejected by the respectable and righteous classes. In contemptuous condemnation He was called the friend of the outcasts (Matt. xi. 19; Mark ii. 16–17), and on His part He proclaimed that these sinners would enter into the Kingdom of Heaven before the self-righteous saints (Matt. xxi. 31); even the most repulsive forms of disease and sin drew from Him only loving aid, while he recognized in all other men who laboured for the welfare of their fellows the most intimate relationship to Himself; these constituted His family, and these were they whom His Father will bless.

Jesus recognized His unique position; He could not be ignorant of His powers. Even the prophets had spoken in the name of God; they accepted neither book nor priesthood as authoritative, but uttered their truth as they were inspired to speak, and commanded men to listen and obey. As in Jesus the whole prophetic line culminates, so does its consciousness; reverent toward the Holy Scriptures, He spoke not as their expositor but with a power which invests His words with immediate and full authority. The prophets used the formula, "Thus saith the Lord," but He goes beyond them and speaks in His own name. He believed Himself to be the Messiah of whom the prophets spoke, and only through this self-consciousness can we explain His mission and the career of His disciples. The prophets up to John foretold the coming of the kingdom (Matt. xi. 11–13; Luke xvi. 16), but Jesus opened its doors and made possible entrance into it. Where He is there it is, and hence those who follow Him are God's children, and those who refuse His message are left outside in darkness. He is to sit as enthroned, judge and king, and by Him is men's future to be determined (Matt. xxv. 31 f.; Mark xiii. 26); indeed it was His presence more than His teaching which created His Church. Great as were His words, greater was His personality. His disciples misunderstood what He said, but they trusted and followed Him. By Him they felt themselves freed from sin and fear—and under the influence of a divine power.

Messianic Claims.—Though His claims to authoritative pre-eminence thus took Him out of the class of prophets and put Him even above Elijah and Moses (Mark ix. 2–7; Luke vii. 28; Luke x. 23–24), and though naturally this self-assertion seemed blasphemous to those who did not accept Him, yet as He had transformed the traditional notion of the kingdom, so did He the current thought of the Messiah. The pre-eminence was not to be of rank and glory but of service and self-sacrifice. In His kingdom there can be no strife for precedence, since its King comes not to be ministered unto but to minister and to give His life in the service of others (Mark ix. 33 f., x. 42–45). The formal acknowledgment of the Messiah's worth and position matters little, for to call Him Lord does not ensure entrance into His Kingdom (Matt. vii. 21–23). It is those who fail to recognize the spirit of sympathy and self-sacrificing service as divine and blaspheme redeeming love who are in danger of eternal sin (Mark iii. 28–29). All who do the will of the Father, *i.e.*, who serve their fellows, are the brethren of Christ, even though they do not call Him Lord (Mark iii. 31–35; Matt. vii. 21): and those are blessed who minister to the needy even though ignorant of any relation to Himself (Matt. xxv. 37–40). Finally, membership in His own selected company, or a place in the chosen people, is not of prime importance (Mark ix. 38–40; Luke xiii. 24–30).

Jesus also refuses to conform to the current ideas as to the establishment of the kingdom. The tradition of the people implied a sudden appearance of the Messiah, but Jesus made no claims to a supernatural origin and was content to be known as the son of Joseph and Mary (Mark vi. 3–4). His kingdom is not to be set up by wonders and miraculous powers, nor is it to be established by force (Matt. xxvi. 52); such means would contradict its fundamental character, for as the kingdom of loving service it can be established only by loving service. Even the disciples of Jesus could not grasp the simplicity and profundity of His message; still less could His opponents. He was accused of blasphemy to the ecclesiastical authorities and of insurrection to the civil rulers. He was condemned and crucified. His followers were scattered. Of His work nothing remained, not a written word, nor more than the rudiments of an organization. The decisive event, which turned defeat into victory and re-established courage and faith, was the belief in the reappearance to His disciples. Our sources will not permit the precise determination of the order or the nature of these appearances, but in any case from them arose the faith which was the basis of the Christian Church and the starting-point of its theology.

The death of Jesus as a criminal, and His resurrection, profoundly aroused the belief and hopes of the little group of Jews who were His followers. It is not His word but His person which assumes first place, and faith is acceptance of Him—crucified and risen—as Messiah. Hence His followers early acquire the name Christian from the Greek form of the word. With this emphasis upon the Messiah the Jewish element would seem to be predominant, but as a matter of fact it was not so. The earlier group of disciples, it is true, did not appreciate the universality of the teaching of Jesus, and they continued zealous for the older forms; but Paul through his prophetic consciousness grasped the fundamental fact and in this respect became Jesus' true interpreter. As a result Christianity was rejected by the Jews and became the conquering religion of the Roman empire. In this it underwent another modification of far-reaching consequence.

In our earliest sources—the epistles of St. Paul—Christ is the pre-existent divine man from heaven, He is before and above all things, and had come to earth by a voluntary act of self-humiliation. In the Johannine writings He is the Son of God—the Logos who in the beginning was with God—of Whom are all things—Who lightens every man—and Who was incarnate in Jesus. Here the cosmological element is again made prominent though not yet supreme, and the metaphysical problems are so close at hand that their discussion is imperative. Even in Paul the term Messiah thus had lost its definite meaning and became almost a proper name. Among the Greek Christians this process was complete. Jesus is the "Son of God"; and the great problem of theology becomes explicit. Religion is in our emotions of reverence

and dependence, and theology is the intellectual attempt to describe the object of worship. Doubtless the two do not exactly coincide, not only because accuracy is difficult or even impossible, but also because elements are admitted into the definition of God which are derived from various sources quite distinct from religious experience. Like all concepts the meaning of religious terms is changed with a changing experience and a changing world-view. Transplanted into the world where Greek ideas were prevalent, inevitably the Christian teaching was modified—indeed transformed. Questions which had never been asked came into the foreground, and the Jewish presuppositions tended to disappear, and the Messianic hopes were forgotten or transferred to a transcendent sphere beyond death. When the empire became Christian in the 4th century, the notion of a kingdom of Christ on earth to be introduced by a great struggle all but disappeared, remaining only as the faith of obscure groups. As thus the background is changed from Jewish to Greek, so are the fundamental religious conceptions.

The Semitic peoples were essentially theocratic; they used the forms of the sensuous imagination in setting forth the realities of the unseen world. They were not given to metaphysical speculation, nor long insistent in their inquiries as to the meaning and origin of things. With the Greeks it was far otherwise: for them ideas and not images set forth fundamental reality, and their restless intellectual activity would be content with nothing but the ultimate truth. Their speculation as to the nature of God had led them gradually to separate Him by an infinite distance from all creation, and to feel keenly the opposition of the finite and the infinite, the perfect and the imperfect, the eternal and the temporal. To them, therefore, Christianity presented itself not primarily as the religion of a redemption through the indwelling power of a risen Saviour, as with Paul, nor even as the solution of the problem how the sins of men could be forgiven, but as the reconciliation of the antinomy of the intellect, indicated above. The incarnation became the great truth: God is no longer separated by a measureless distance from the human race, but by His entering into humanity He redeems it and makes possible its ultimate unity with Himself. Such lines of thought provoke discussion as to the relationship of Jesus to God the Father, and, at a later period, of the nature of the Holy Spirit who enters into and transforms believers.

Greek philosophy in the 2nd century A.D. had sunk for the most part into scepticism and impotence; its original impulse had been lost, and no new intellectual power took its place; only in Alexandria was there a genuine effort made to solve the fundamental problems of God and the world; and mingled with the speculations of the Greek philosophers were the ancient legends of gods and heroes, accepted as inspired scripture by the people, and by the philosophers in part explained away by an allegorical exegesis and in part felt increasingly as a burden to the intelligence. In this period of degeneracy there were none the less an awakening to religious needs and a profound longing for a new revelation of truth, which should satisfy at once the intellect and the religious emotions.

Christianity came as supplying a new power; it freed philosophy from scepticism by giving a definite object to its efforts and a renewed confidence in its mission. Monotheism henceforth was to be the belief not of philosophers only but even of the ignorant, and in Jesus Christ the union of the divine and the human was effected. The Old Testament, allegorically explained, became the substitute for the outgrown mythology; intellectual activity revived; the new facts gained predominant influence in philosophy, and in turn were shaped according to its canons. In theology the fundamental problems of ontological philosophy were faced; the relationship of unity to multiplicity, of noumenon to phenomena, of God to man. The new element is the historical Jesus, at once the representative of humanity and of God. As in philosophy, so now in theology, the easiest solution of the problem was the denial of one of its factors: and successively these efforts were made, until a solution was believed to be found which satisfied both terms of the equation and became the fundamental creed of the Church. Its moulds of thought are those of Greek philosophy, and into these were run the Jewish teachings. We have thus a peculiar combination—the religious doctrines of the Bible, as culminating in the person of Jesus, run through the forms of an alien philosophy.

The Doctrine of the Trinity.—The Jewish sources furnished the terms Father, Son and Spirit. Jesus seldom employed the last term and Paul's use of it is not altogether clear. Already in Jewish literature it had been all but personified (*cf.* the *Wisdom of Solomon*). Thus the material is Jewish, though already doubtless modified by Greek influence: but the problem is Greek; it is not primarily ethical nor even religious, but it is metaphysical. What is the ontological relationship between these three factors? The answer of the Church is given in the Nicene formula, which is characteristically Greek, and which affirms that God, the infinite, the absolute, the eternal, is yet not separated from the finite, the temporal, the relative, but, through the incarnation, enters into humanity (*see* ARIUS and ATHANASIUS "THE GREAT"). This entering into humanity is not an isolated act but continues in all the children of God by the indwelling Spirit. Thus, according to the canons of ancient philosophy, justice is done to all the factors of our problem—God remains as Father, the infinitely remote and absolute source of all; as Son, the Word Who is revealed to man and incarnate in Him; as Spirit, Who dwells even in our own souls and by His substance unites us to God.

Jesus was the central fact of faith, because he had led the disciples to God. After the resurrection He was the object of praise, and soon prayers were offered in His name and to Him. Already to the apostle Paul He dominates the world and is above all created things, visible and invisible, so that He has the religious value of God. Metaphysics and speculative theories were valueless for Paul; he was conscious of a mighty power transforming his own life and filling him with joy, and that this power was identical with Jesus of Nazareth he knew. In all this Paul is the representative of that which is highest and best in early Christianity. Speculation and hyperspiritualization were ever tending to obscure this fundamental religious fact: in the interest of a higher doctrine of God His true presence in Jesus was denied, and by exaggeration of Paul's doctrine of "Christ in us" the significance of the historic Jesus was given up. The Johannine writings, which presupposed the Pauline movement, are a protest against the hyperspiritualizing tendency. They insist that the Son of God has been incarnate in Jesus of Nazareth, and that our hands have handled and our eyes have seen the word of life. This same purpose, namely, to hold fast to the historic Jesus, triumphed in the Nicene formula; Jesus was not to be resolved into an aeon or into some mysterious *tertium quid*, neither God nor man, but to be recognized as very God who redeemed the soul. Through Him men were to understand the Father and to understand themselves as God's children.

It is apparent that such a doctrine as the Trinity is itself susceptible of many explanations, particularly as to the distinction and relation between God the Eternal Son and God the Holy Spirit; and minds differently constituted lay emphasis upon its different elements. Especially is this true as its Greek terminology was translated into Latin, and from Latin came into modern languages—the original meaning being obscured or disguised, and the original issues forgotten. For some the first thought of God, the infinite and ultimate reality lying beyond and behind all phenomena, predominates. With these the historic manifestation of Jesus becomes only a guide to lead us to that immediate apprehension of God which is the end of theology, and to that immediate union with God which is the end of religion. Such an end is accomplished either by means of pure thought or by a oneness of pure feeling, giving as results the theological or philosophical construction of the idea of God, or a mystical ecstasy which is itself at once immediate, inexplicable and indescribable. On the other hand, minds of a different and more concrete character so emphasize the distinctions God, Son and Holy Spirit, that a tritheistic construction appears—three individuals in the one Godhead: these individuals appearing, as for example, in the Father and the Son, even in opposition to each other. In general we may say then that the Trinity takes on

three differing aspects in the Christian Church: in its more common and easily apprehended form as three Gods; in its ecclesiastical form as a mystery which is above reason to be accepted by faith; in its philosophic form as a metaphysical interpretation of the finite, the infinite and the relation between them.

To some Christians the doctrine of the Trinity appeared inconsistent with the unity of God which is emphasized in the Scriptures. They therefore denied it, and accepted Jesus Christ, not as incarnate God, but as God's highest creature by Whom all else was created, or as the perfect man who taught the true doctrine of God. The first view in the early Church long contended with the orthodox doctrine, but finally disappeared, and the second doctrine in the modern Church was set forth as easily intelligible, but has remained as a form of "heresy."

The Cross and the Atonement.—Allied with the doctrine of God which seeks the solution of the ultimate problem of all philosophy, the doctrine of salvation has taken the most prominent place in the Christian faith: so prominent, indeed, that to a large portion of believers it has been the supreme doctrine, and the doctrine of the deity of Jesus has been valued only because of its necessity on the effect of the atonement. Jesus alone of the great founders of religion suffered an early and violent death, even the death of a criminal. It became therefore the immediate task of His followers to explain this fact. This explanation was the more urgent because under the influence of Jewish monotheism the rule of God was accepted as an undoubted presupposition, so that the death of Jesus must be in accordance with His will. The early Church naturally used the term and phrases of the prophets. He died the death of a criminal, not for His sins, but for ours. Isaiah liii. was suggested at once and became the central explanation: Christ is the suffering servant Who is numbered with the transgressors and Who bears the sins of many.

It is remarkable that in the earliest centuries of Christian thought there is only the most slender support for theories of the Atonement which became widely current at a later time. The early Fathers did not regard the sufferings of Christ as a vicarious satisfaction of God's wrath, where He underwent punishment due to us and His obedience is imputed to us. Whenever they use language which seems to convey such ideas, they as it were instinctively safeguard it by the idea of our union with Christ, where we share in His obedience and His passion, and only so far as we make them our own do we actually appropriate the redemption He won for us. Their main thought is that man is reconciled to God by the Atonement, and not God to man; the change which it effects is a change in man rather than a change in God. Many centuries later the familiar outlines of the theory of vicarious atonement were drawn, and carved into a rigid scheme by the Reformers. They were deeply convinced that human sin is the violation of an eternal law which has its basis in the very being of God and is the expression of God's justice, which must be satisfied. This is the conviction embodied in the Protestant creeds, and worked out by means of metaphors so legal and even mechanical in character that modern theology has been marked by a widespread revolt against every form of it.

A large part of the history of Christian doctrine deals with controversies arising from theories of the Atonement (*q.v.*); but excepting in relatively narrow circles these theories have been seriously studied only by professed theologians. That Christ died for us, and that we are saved by Him, is indeed the living truth of the Church in all ages, and a false impression of the fact is given by dwelling upon theories as if they were central. At best they bear only the relationship of philosophy to life.

These hopes and theories of salvation do not indeed wholly explain the power of Christianity. Jesus wearied Himself with the healing of man's physical ailments, and He was remembered as the great physician. Early Christian literature is filled with medical terms, applied (it is true) for the greater part to the cure of souls. The records of the Church are also filled with the efforts of Jesus's followers to heal the diseases and satisfy the wants of men. A vast activity animated the early Church: to heal the sick, to feed the hungry, to succour the diseased, to rescue the fallen, to visit the prisoners, to forgive the erring, to teach the ignorant, were ministries of salvation. A mighty power impelled men to deny themselves in the service of others, and to find in this service their own true life. None the less the first place is given to the salvation of the soul, since, created for an unending existence, it is of transcendent importance. While man is fallen and by nature vile, nevertheless his possibilities are so vast that in comparison the affairs of earth are insignificant. The word, "What shall it profit a man if he gain the whole world and lose his own soul?" comes to mean that the individual soul outvalues the whole world. With emphasis upon God as creator and ruler, and upon man as made in God's image, endowed with an unending existence, and subject to eternal torture if not redeemed, the concept of personality has been exalted at the expense of that of nature, and the future has been magnified at the expense of the present. Thus a future heaven is man's true home, and theology instead of philosophy or natural science is his proper study.

Indeed, intellectual interest centred in religion. Natural science was forsaken, except in so far as it ministered to theology. Because the Old Testament contained references to the origin and the objects of the universe, a certain amount of natural science was necessary, but it was only in this connection that it had any value. By Augustine's time this process is complete. His writings contain most of the knowledge of his age, but it is strictly subordinate to his theological purpose. Hence, when the barbarians submerged southern Europe, theology alone survived. The Church entered upon a new task. In the beginning Christianity had been the teacher of religion to highly civilized peoples —now it became the civilizing agent to the barbarians, the teacher of better customs, the upholder of law and the source of knowledge. The learned men were monks and priests, and the universities were Church institutions.

The Sacraments and Salvation.—Belief in mysterious powers attached to food, feasts, ceremonial rites and sacred things is all but universal. Primitive man seldom connects sacrifice with notions of propitiation, indeed only in highly ethicized religions is the consciousness of sin or of guilt pre-eminent. Sacrifice was believed to exert an influence on the deity which is quasi-physical, and in sacrificial feasts God and worshipper are in mysterious union.

So universal are such ideas that the problem in particular religions is not their origin but their form. In the Old Testament repeatedly they are found in conflict with the prophetic ideals. Sometimes the prophets denounce them, sometimes ignore them, sometimes attempt to reform and control them. Jesus ignores them, His emphasis being so strong upon the ethical and spiritual that the rest is passed by. In the early Church, still Jewish, the belief was in the coming of a mysterious power from God which produced ecstasy and worked wonders. Paul also believes in this but insists that it is subordinate to the peaceable fruits of righteousness. With the naturalization of the Church in the Gentile world ethical ideas became less prominent, and the sacramental system prevailed. By baptism and the Lord's Supper grace is given (*ex opere operato*), so that man is renewed and made capable of salvation. Already in the 2nd century baptism was described as a bath in which the health of the soul is restored, and the Lord's Supper as the potion of immortality. Similar notions present in the ethnic faiths take the Christian facts into their service, the belief of the multitude without essential change remaining vague and undefined. While the theologians discussed doctrine the people longed for mystery, as it satisfied their religious natures; by sacraments they felt themselves brought into the presence of God, and to sacraments they looked for aid. Many sacraments were adopted by portions of the Church, until at last the sacred number seven was agreed upon.

In the earliest period the services were characterized by extreme freedom, and by manifestations of ecstasy which were believed to indicate the presence of the spirit of God; but as time went on the original enthusiasm faded away, the cult became more and more controlled, until ultimately it was completely subject to the priesthood, and through the priesthood to the Church. The power of the priesthood had its centre in the sacrament of the Eucharist (*q.v.*), and in the Roman communion the structure of

the sacred edifice, the positions and attitudes of the priest and the congregation, the order of service, emphasize the mystery and the divine efficacy of the sacrament. The worshipper feels himself in the immediate presence of God, and enters into physical relations with him; participation in the mass also releases from guilt, as the Lamb of God offered up atones for sin and intercedes with the Father in our behalf. Thus in this single act of devotion both objects of all cults are attained.

Organization.—As the teaching and person of Jesus were fitted into the framework of Greek philosophy, and the sacraments into the deeper and broader forms of popular belief, so was the organization shaped by the polity of the Roman empire. Jesus gathered His group of followers and committed to it His mission, and after His resurrection the necessities of the situation brought about the choice of quasi-officials. Later the familiar polity of the synagogue was loosely followed. A completer organization was retarded by two factors, the presence of the apostles and the inspiration of the prophets. But when the apostles died and the early enthusiasm disappeared, a stricter order arose. Practical difficulties called for the enforcement of discipline, and differences of opinion for authority in doctrine; and, finally, the sacramentarian system required a priesthood. In the 2nd century the conception of a Catholic Church was widely held and a loose embodiment was given it; after the conversion of the empire the organization took on the official forms of the empire. Later it was modified by the rise of the feudal system and the re-establishment of the modern European nationalities.

The polity of the Church was more than a formal organization; it touched the life of each believer. Very early, Christianity was conceived to be a new system of law, and faith was interpreted as obedience. Legalism was joined with sacramentarianism, doubling the power of the priest. Through him Church discipline was administered, a complete system of ecclesiastical penalties, *i.e.*, penance, growing up. It culminated in the doctrine of purgatory, a place of discipline, of purifying suffering after death. The Roman genius for law strengthened and systematized this tendency.

The Roman Church.—The hierarchy which centres in the pope constitutes the Church of which the sacramental system is the inner life and penance is the sanction. It is thus a divine-human organization. It teaches that the divine-human Son of God established it, and returning to heaven committed to the apostles, especially to St. Peter, his authority, which has descended in an unbroken line through the popes. This is the charter of the Church, and its acceptance is the first requisite for salvation; for the Church determines doctrine, exercises discipline and administers sacraments. Its authority is accompanied by the spirit of God, who guides it into truth and gives it miraculous power. Outside the Church are only the "broken lights" of man's philosophy and the vain efforts of weak human nature after virtue.

Christianity in its complete Roman development is thus the coming of the supernatural into the natural. The universe falls into these orders, the second for the sake of the first, as nature is of and for God. Without Him nature at its highest is like a beautiful statue, devoid of life; it is of secondary moment compared even to men, for while it passes away he continues for ever. Man is dependent, therefore, not upon nature, but upon God's grace for salvation, and this comes through the Church. Thus the Church ever receives God and has a twofold nature; its sacraments through material and earthly elements impart a divine power; its teachings agree with the highest truths of philosophy and science, yet add to these the knowledge of mysteries which the unaided reason of man could never apprehend. Theology is the queen of the sciences, and nothing should be taught in school or university which contradicts its conclusions. Moreover, nothing should be done by the State which interferes with the transcendent interest committed to the Church. Thus the Church touches and controls all realms of life, and the cycle is complete.

The Reformation.—The idea of the Roman Church was imperfectly embodied at the best; the divine gift was in earthen vessels. The world was never completely cast out; indeed the Church became the scene for ambition and the home of luxury and pleasure. It was entangled also in the political strife of the feudal ages and of the beginning of modern empires. Its control of the sciences embroiled it with its own philosophers and scholars, while saints and pure-minded ecclesiastics attempted, without success, its reform from within. Finally, through Luther, the explosion came, and western Christendom broke into two parts—Catholic and Protestant.

Protestantism in its primary principle is the return to primitive Christianity. The whole development which we have traced, culminating in the ecclesiastical-doctrinal system of the Roman Church, is regarded as a corruption, since foreign and even heathen elements have been brought in, so that the religion established by Christ is obscured or lost. For Protestants the Bible only now becomes the infallible inspired authority in faith and morals. Interpretations by the Fathers or by the councils are to be taken only as aids to its understanding. But in Protestantism reason and the light of nature are in themselves as impotent as in the Roman Church. The Bible interpreted by man's unaided intelligence is as valueless as other writings, but it has a sacramental value when the Holy Spirit accompanies its teaching, and the power of God uses it and makes the soul capable of holiness. In all this the supernatural is as vividly realized as in the Roman Church; it is only its mediation which is different.

These principles are variously worked out in the different churches and variously expressed. In part because of historical circumstances, the divergence from the older systems is more marked in some Protestant churches than in others, yet on the whole these two principles determine cult and in part organization. As in the Roman Church cult centres in the mass, so in the original Reformed Church it centred in the sermon. The ancient Jewish prophetic office was revived, yet with a difference: the ancient prophets acknowledged no external authority, but the Protestant preacher is strictly subordinate to the Scriptures of which he is the interpreter. Besides the sermon, the sacraments are observed as established by Christ—two in number, baptism and the Lord's Supper. But these do not exert a quasi-physical or magical influence, *ex opere operato*. Unless there be faith in the recipient, an understanding of the meaning of the sacrament and an acceptance of it, it is valueless or harmful. Prayer and praise also are effective only as the congregation intelligently joins in them.

The emphasis upon the believer and his freedom from all external authority do not result in a thoroughgoing individualism. Luther clearly held to the unity of all Christians, and Protestants are agreed in this. For them, as for the Roman Church, there is a belief in a catholic or all-embracing Church, but the unity is not that of an organization; Christians are one through an indwelling spirit; they undergo the same experience and follow the same purpose.

Historically these principles were only in part embodied, for the Reformation was involved in political strife. The Reformers turned to the Government for aid and protection, and throughout Europe turmoil and war ensued. In consequence, in the Protestant nations the State assumed the ultimate authority over the Church. Moreover, in the early days of the Reformation the Catholic Church charged it with a lawless individualism, a charge which was seemingly made good by an extreme divergence in theological opinion and by riots in various part of the Protestant world. The age was indeed one of ferment, so that the foundations of society and of religion seemed threatened. The Reformers turned to the State for protection against the Roman Church, and ultimately as a refuge from anarchy, and they also returned to the theology of the Fathers as their safeguard against heresy. Instead of the simplicity of Luther's earlier writings, a dogmatic theology was formed, and a Protestant ecclesiasticism established, indistinguishable from the Roman Church in principle. The main difference was in the attitude to the Roman allegiance and to the sacramentarian system. There was thus by no means a complete return to the Bible as the sole authority, but the Bible was taken as interpreted by the earlier creeds and as worked into a doctrinal system by the scholastic philosophy. Thus Protestantism also came to identify theology with the whole range of human knowledge, and in its official forms was as hostile to the progress

of science as was the Roman Church itself.

Many Protestants rebelled against this radical departure from the principles of the Reformation and of biblical Christianity. To them it seems the substitution of the authority of the Church for the authority of a living experience, and of intellectual adherence to theological propositions for faith. The freedom of the individual was denied. Protestantism divided into many sects and denominations, founded upon special types of religious experience or upon particular points in doctrine or in cult. Thus Protestantism presents a wide diversity in comparison with the regularity of the Roman Church (*see* REUNION, CHURCH).

Christianity and the Modern World.—The coming of the northern peoples into the Roman world profoundly modified Christianity. It shared indeed in the dreariness and corruption of the times commonly called the "dark ages," but when at last a productive period began the Church was the first to profit by it. Since all educated men were priests, it assimilated the new learning—the revived Aristotelianism—and continued its control of the universities. In the 13th century it was supreme, and Christianity was identified with world systems of knowledge and politics. Both were deemed alike divine in origin, and to question their validity was an offence against God. Christianity thus had passed through three stages in politics as in science. At first it was persecuted by the State, then established by it, and finally dominated over it; so its teaching was at first alien to philosophy and despised by it, next was accepted by it and given form and rights through it, and finally became queen of the sciences as theology and ruled over the whole world of human knowledge. But the triumph by its completeness ensured new conflicts; from the disorder of the middle ages arose states which ultimately asserted complete autonomy, and in like fashion new intellectual powers came forth which ultimately established the independence of the sciences.

In the broadest sense the underlying principle of the struggle is the reassertion of interest in the world. It is no longer merely the scene for the drama of the soul and God, nor is man independent of it, but man and nature constitute an organism, humanity being a part of the vaster whole. Man's place is not even central, as he appears a temporary inhabitant of a minor planet in one of the lesser stellar systems. As in the political world the States gained first the undisputed control of matters secular, rejecting even the proffered counsel of the Church, and then proceeded to establish their sovereignty over the Church itself, so was it in the empire of the mind. The rights gained for independent research were extended over the realm of religion also; the two indeed cannot remain separate, and man must subordinate knowledge to the authority of religion—or make science supreme, submitting religion to its scrutiny and judging it like other phenomena. Under this investigation Christianity does not appear altogether exceptional. Its early logic, ontology, and cosmology, with many of its distinctive doctrines, are shown to be the natural offspring of the races and ages which gave them birth. Put into their historical environment they are found to be steps in the intellectual development of man's mind. But when put forward as absolute truths to-day, they are put aside as anachronisms not worthy of dispute. The Bible is studied like other works, its origins discovered and its place in comparative religion assigned. It does not appear as altogether unique, but it is put among the other sacred books. For the great religions of the world show similar cycles of development, similar appropriations of prevalent science and philosophy, similar conservative insistence upon ancient truth, and similar claims to an exclusive authority.

With this interest is involved an attitude of mind toward the supernatural. As already pointed out, nature and super-nature were taken as physically and spatially distinct. The latter could descend upon the former and be imparted to it, neither subject to nature nor intelligible by reason. In science the process has been reversed; nature ascends, so to speak, into the region of the supernatural and subdues it to itself; the marvellous or miraculous is brought under the domain of natural law, the canons of physics extend over metaphysics, and religion takes its place as one element in the natural relationship of man to his environment. Hence the new world-view threatens the foundations of the ecclesiastical edifice. This revolution in the world-view is no longer the possession of philosophers and scholars, but the multitude accepts it in part. Education in general has rendered many familiar with the teachings of science, and, moreover, its practical benefits have given authority to its maxims and theories.

The *Roman Catholic Church* uncompromisingly reasserts its ancient propositions, political and theological. The cause is lost indeed in the political realm, where the Church is obliged to submit, but it protests and does not waive or modify its claims (*see* the *Syllabus* of 1864, par. 19 *seq.*, 27, 54 and 55). In the Greek and Protestant churches this situation cannot arise, as they make no claims to governmental sovereignty. In the intellectual domain the situation is more complex. Again the Roman Church unhesitatingly reaffirms the ancient principles in their extreme form (*Syllabus*, par. 8–9–13; *Decrees of the Vatican Council*, ch. 4, especially canon 4–2); the works of St. Thomas Aquinas are recommended as the standard authority in theology (Encyc. of Leo XIII., *Aeterni Patris*, Aug. 4, 1879). In details also the conclusions of modern science are rejected, as for example the origin of man from lower species, and, in a different sphere, the conclusions of experts as to the origins of the Bible. Faith is defined as "assent upon authority," and the authority is the Church, which maintains its right to supremacy over the whole domain of science and philosophy.

The *Greek Church* remains untouched by the modern spirit. With characteristic oriental conservatism it claims the title of "Orthodox" and retains the creed and organization of the early Church. The *Protestant Churches* also are bound officially to the scholastic philosophy of the 17th century; their confessions of faith still assert the formation of the world in six days, and require assent to propositions which can be true only if the old cosmology be correct.

Compromises.—On the other hand there are individuals and even large bodies of Christians who are intent upon a reinterpretation. Even in the official circles of the Church, not excepting the Roman Church, there are many scholars who find no difficulty in maintaining communion while accepting the modern scientific view of the world. This is possible to some because the situation in its sharp antithesis is not present to their minds: by making certain compromises on the one side and on the other, and by framing private interpretations of important dogmas, they can retain their faith in both and yet preserve their mental integrity.

Thus the crisis is in fact not so acute as it might seem. No great institution lives or dies by logic. Christianity rests on great religious needs which it meets and gratifies, so that its life (like all other lives) is in unrationalized emotions. Reason seeks ever to rationalize these, an attempt which seems to destroy yet really fulfils. As thus the restless reason tests the emotions of the soul, criticizes the traditions to which they cling, rejects the ancient dogmas in which they have been defined, the Church slowly participates in the process; silently this position and that are forsaken, legends and beliefs once of prime importance are forgotten, or when forced into controversy many ways are found by which the old and the new are reconciled; the sharpness of distinctions can be rubbed off, expressions may be softened, definitions can be modified and half-way resting-places afforded, until the momentous transition has been made and the continuity of tradition is maintained. Finally, as the last step, even the official documents may be revised.

Philosophy and Ethical Redemption.—The intellectual crisis cannot be ignored in the interest of the practical life. Men must rationalize the universe. On the one hand there are churchmen who attempt to repeat the historical process which has naturalized the Church in alien soils by appropriating the forces of the new environment, and who hold that the entire process is inspired and guided by the spirit of God. Hence Christianity is the absolute religion, because it does not preclude development but necessitates it, so that the Christianity that is to come shall not only retain all that is important in the Christianity of the past and present but shall assimilate new truth. On the other hand some seek the essential Christianity in a life beneath and separable from the historic forms. In part under the influence of the Hegelian

philosophy, and in part because of the prevalent evolutionary scientific world-view, God is represented under the form of pure thought, and the world process as the unfolding of Himself. Such truth can be apprehended by the multitude only in symbols which guide the will through the imagination, and through historic facts which are embodiment of ideas. The Trinity is the essential Christian doctrine, the historic facts of the Christian religion being the embodiment of religious ideas. The chief critical difficulty felt by this school is in identifying any concrete historic fact with the unchanging idea, that is, in making Jesus of Nazareth the incarnation of God. God is reinterpreted, and in place of an extra-mundane creator is an omnipresent life and power. The Christian attainment is nothing else than the thorough intellectual grasp of the absolute idea and the identification of our essential selves with God. With a less thoroughgoing intellectualism other scholars reinterpret Christianity in terms of current scientific phraseology. Christianity is dependent upon the understanding of the universe; hence it is the duty of believers to put it into the new setting, so that it adopts and adapts astronomy, geology, biology and psychology.

From all these efforts to reconstruct systematic theology with its appropriations of philosophy and science, groups of Christians turn to the inner life and seek in its realities to find the confirmation of their faith. They also claim oneness with a long line of Christians, for in every age there have been men who have ignored the dogma and the ritual of the Church, and in contemplation and retirement have sought to know God immediately in their own experience. To them at best theology with its cosmology and its logic is only a shadow of shadows, for God reveals himself to the pure in heart, and it matters not what science may say of the material and fleeting world. This spirit manifests itself in wide circles in our day. The Gordian knot is cut, for philosophy and religion no longer touch each other but abide in separate realms.

In quite a different way a still more influential school seeks essential Christianity in the sphere of the ethical life. It also would disentangle religion from cosmology and formal philosophy. It studies the historic development of the Church, noting how element after element has been introduced into the simplicity of the gospel, and from all these it would turn back to the Bible itself. In a thoroughgoing fashion it would accomplish what Luther and the Reformation attempted. It regards even the earliest creeds as only more or less satisfactory attempts to translate the Christian facts into the current language of the heathen world. But the process does not stop with this rejection of the ancient and the scholastic theology. It recognizes the scientific results attained in the study of the Bible itself, and therefore it does not seek the entire Bible as its rule of truth. To it Jesus Christ, and He alone, is supreme, but this supremacy does not carry with it infallibility in the realm of cosmology or of history. In these too Jesus participated in the views of His own time; even His teaching of God and of the future life is not lacking in Jewish elements, yet none the less He is the essential element in Christianity, and to His life-purpose must all that claims to be Christianity be brought to be judged. To this school Christianity is the culmination of the ethical monotheism of the Old Testament, which finds its highest ideal in self-sacrificing love. Jesus Christ is the complete embodiment of this ideal, in life and in death This ideal He sets before men under the traditional forms of the Kingdom of God as the object to be attained, a Kingdom which takes upon itself the forms of the family, and realizes itself in a new relationship of universal brotherhood. Such a religion appeals for its self-verification not to its agreement with cosmological conceptions, either ancient or modern, or with theories of philosophy, however true these may be, but to the moral sense of man. On the one hand, in its ethical development, it is nothing less than the outworking of that principle of Jesus Christ which led Him not only to self-sacrificing labour but to the death upon the cross. On the other hand, it finds its religious solution in the trust in a power not ourselves which makes for the same righteousness which was incarnate in Jesus Christ.

Thus Christianity, as religion, is on the one hand the adoration of God, that is, of the highest and noblest, and this highest and noblest as conceived not under forms of power or knowledge but in the form of ethical self-devotion as embodied in Jesus Christ, and on the other hand it meets the requirements of all religion in its dependence, not indeed upon some absolute idea or omnipotent power, but in the belief that that which appeals to the soul as worthy of supreme worship is also that in which the soul may trust, and which shall deliver it from sin and fear and death. Such a conception of Christianity can recognize many embodiments in ritual, organization and dogma, but its test in all ages and in all lands is conformity to the purpose of the life of Christ. The Lord's Prayer in its oldest and simplest form is the expression of its faith, and Christ's separation of mankind on the right hand and on the left in accordance with their service or refusal of service to their fellow-men is its own judgment of the right of any age or Church to the name Christian.

Christianity has passed through too many changes, and it has found too many interpretations possible, to fear the time to come. Thoroughgoing reconstruction in every item of theology and in every detail of polity there may be, yet shall the Christian life go on—the life which finds its deepest utterance in the words of Christ, "Thou shalt love the Lord thy God with all thy heart and thy neighbour as thyself"; the life which expresses its profoundest faith in the words Christ taught it to pray, "Our Father"; the life which finds its highest rule of conduct in the words of its first and greatest interpreter, "Let this mind be in you which was also in Christ Jesus our Lord."

The view that Jesus deliberately founded a Church (an ecclesiastical institution), appointed the Apostles its rulers, settled its rites, gave it its doctrine and guaranteed its fidelity, can only be maintained by discarding history altogether. In the 19th century this was transformed into the view that Jesus planted "in germ" what has grown to be the present Catholic doctrine and order. Among those who differ only in detail about what happened, there are, however, diametrically opposite judgments of the value of the change. (i.) Liberal Protestant scholars, on the whole, regard it as the kind of corruption to which religions are always subject as they absorb alien elements with their imperfectly instructed converts. They find the essential Christian element to be a power, shown by no other religion, first of elevating and spiritualizing these alien elements and then of eliminating them. This they ascribe to the higher idea of redemption inseparable from the faith in Christ (which, however much overlaid, has always wrought like leaven), and to what goes with it—the Revelation of the Father. Thus, for them, an essential quality of Christianity is its power to regenerate itself by a return to the Jesus of the Gospels. They would maintain that all other religions have their place, but it is as a preparation, or if their elements remain in Christianity, it is only as a temporary substitute for the true Christian redemption. (ii.) Liberal Catholic scholars on the other hand regard it as the highest perfection of Christianity that it can thus "syncretize" (absorb and transform) what has appealed to human need in any religion. By this comprehensiveness, they maintain, Christianity, from being an enthusiastic but incoherent movement, grew into a permanent and effective institution, with its original puritanism enriched in all kinds of religiously valuable ways.

The foregoing statement is a definition not of two positions but of two *directions*, and allows for various intermediate doctrines and interpretations. All these are naturally exemplified in the principal branches of organized Christianity, and reference must be made to the various articles on these subjects: ROMAN CATHOLIC CHURCH; ENGLAND, CHURCH OF; PRESBYTERIANISM; LUTHERANS; CONGREGATIONALISM; METHODISM; etc.

BIBLIOGRAPHY.—On such a vast subject we can here refer to only a few of those books which give guidance for further study and are typical of each of its main lines. For Roman Catholicism: P. Batiffol, *L'Église naissante et le catholicisme* (4th ed., 1909); Wilhelm and Scannell, *Manual of Catholic Theology* (1899); C. S. Devas, *The Key to the World's Progress* (1906); and many articles in the *Catholic Encyclopaedia*. For Anglicanism: *Lux Mundi* (1890); Gore, *Orders and Unity* (1909); *The Reconstruction of Belief* (1927); Darwell Stone, *The Church, its Ministry and Authority* (1902); A. C. Headlam (Bishop of Gloucester), *The Church of England* (1927). For the Free Churches: *Towards Reunion*, by Church of England and Free Church writers (1919); G. K. A. Bell, *Documents on Christian Unity*

(1924); G. K. A. Bell and W. Robertson (eds.), *The Church of England and the Free Churches* (1925); A. E. Garvie, "Christianity" in James Hastings' *Encyclopaedia of Religion and Ethics*, 12 vol. (1908–22), for liberal Evangelicalism; J. E. Carpenter (ed.), *Freedom and Truth* (1925), for Unitarian Christianity. *See* also James Drummond, *Via, Veritas, Vita* (Hibbert Lectures, 1894); and Charles Beard, *The Reformation of the Sixteenth Century in Its Relation to Modern Thought and Knowledge* (Hibbert Lectures, 1883; new ed., 1927).

For the principles of Protestantism as a religion: A. Ritschl, *Christian Doctrine of Justification and Reconciliation* (Eng. trans., 1900), most important for its present influence (for a critical estimate, Garvie, *The Ritschlian Theology*, 1897); E. Troeltsch, *Die Absolutheit des Christenthums* (1902); W. Hermann, *Communion of the Christian with God* (Eng. trans., 1895), a discussion in the spirit of Luther; A. Sabatier, *Religions of Authority and the Religion of the Spirit* (Eng. trans., 1904). On primitive Christianity, *see* Harnack, *Mission and Expansion of Christianity in the First Three Centuries* (Eng. trans., 1904); Wernle, *Beginnings of Christianity* (Eng. trans., 1904); Weizsacker, *The Apostolic Age* (Eng. trans., 1897); Edwin Hatch, *Influence of Greek Ideas and Usages upon the Christian Church* (Hibbert Lectures, 1888).

(G. W. Kn.; S. H. M.)

CHRISTIAN OF BRUNSWICK (1599–1626), bishop of Halberstadt, a younger son of Henry Julius, duke of Brunswick-Wolfenbüttel, was born in Groningen, Neth., on, Sept. 20, 1599. Having succeeded his father as "bishop" of Halberstadt in 1616, he obtained some experience of warfare under Maurice, prince of Orange, in the Netherlands. Raising an army he entered the service of Frederick V, elector palatine of the Rhine, and attacked the lands of the elector of Mainz and the bishoprics of Westphalia. After some successes he was defeated by Johann (later Count van) Tilly at Höchst, Prus., in June 1622; then, dismissed from Frederick's service, he entered that of the United Provinces, losing an arm at the battle of Fleurus. In 1623 he was beaten by Tilly at Stadtlohn, Prus., and driven back to the Netherlands. When in 1625 Christian IV, king of Denmark, entered the arena of the war, he took the field again in the Protestant interest, but after some successes he died at Wolfenbüttel, Ger., on June 16, 1626. (*See* also Thirty Years' War.)

Bibliography.—Count van Tilly, *Relacion de la vitoria que de dar al Conde de Tylli contra el Duque Cristiano de Bronzuyque* (Madrid, 1623).

CHRISTIANSAND, a fortified seaport of Norway, the chief town of the diocese (*stift*) of Agder on a fjord of the Skagerrack, 175 mi. S.W. of Oslo. Pop. (est. 1936) 18,781. It stands on a square peninsula flanked by the western and eastern harbours and by the Otter river, among wooded hills and islands. It is a fishing centre (salmon, mackerel, lobsters), with sawmills, woodpulp factories, shipbuilding yards and mechanical workshops. The port is the largest on the south coast; coast and foreign steamers on the way north to Oslo ordinarily touch there. The Saetersdal railway follows that valley north to Byglandsfjord (48 mi.), whence a good road continues to Viken i Valle at the head of the valley. Flekkerö, a neighbouring island, is a favourite pleasure resort. The town was founded in 1641 by Christian IV.

CHRISTIAN SCIENCE, the religion founded by Mary Baker Eddy; the religion represented by the Church of Christ, Scientist. Applicable to health, as the Christian religion originally was, Christian Science is a religious teaching and practice based on the words and works of Christ Jesus. As defined by Mrs. Eddy, it is "divine metaphysics"; it is "the scientific system of divine healing"; it is "the law of God, the law of good, interpreting and demonstrating the divine Principle and rule of universal harmony" (*Science and Health, with Key to the Scriptures*, p. 111, 123; *Rudimental Divine Science*, p. 1). For many years prior to 1866 Mrs. Eddy had observed and studied mental causes and effects. Profoundly religious, she was disposed to attribute causation to God and to regard Him as divine Mind. At Lynn, Mass., in that year, she recovered almost instantly from a severe injury after reading an account of healing in the Gospel according to St. Matthew ix, 1–8. The discovery of what she named Christian Science ensued from this incident. As she has said, "I knew the Principle of all harmonious Mind-action to be God, and that cures were produced in primitive Christian healing by holy, uplifting faith; but I must know the Science of this healing, and I won my way to absolute conclusions through divine revelation, reason and demonstration" (*Science and Health*, p. 109).

At Boston, Mass., in 1875, Mrs. Eddy published her principal work, first called *Science and Health* but afterward entitled *Science and Health, with Key to the Scriptures*. It is known also as the Christian Science textbook. Occasionally revised by the author, "only to be a clearer and fuller expression of its original meaning" (p. 361), this book received from her its final revision in 1907. It is read in Christian Science services in connection with the Bible, and is to be found in all Christian Science reading rooms as well as in public libraries. (For other works on Christian Science by Mrs. Eddy, *see* the bibliography under Eddy, Mary Baker.) Mrs. Eddy also attached great importance to periodical literature. Publications of the church, issued by the Christian Science Publishing society, include *The Christian Science Journal* (1883); the *Christian Science Quarterly* (1890); the *Christian Science Sentinel* (1898); *The Herald of Christian Science*, published in seven foreign languages and in Braille in English; and the *Christian Science Monitor* (1908). All except one of these periodicals circulate chiefly among people who have some degree of interest in Christian Science, but the *Christian Science Monitor* has become established as an excellent newspaper in the estimation of many people who are entirely indifferent toward the religion which it promotes but does not obtrude or even stress.

At first, Mrs. Eddy did not expect to found a distinct church or denomination; she hoped that her discovery would be accepted soon by existing churches. In a short time, however, a distinct church became needed to facilitate co-operation and unity between Christian Scientists, to present Christian Science to other people and to maintain the purity of its teaching and practice. Accordingly, at Boston, in 1879, Mrs. Eddy with her followers founded the Church of Christ, Scientist. Soon the original organization became inadequate for the growing denomination. To the first congregation in Boston there were added numbers of Christian Scientists at other places. Local churches as well as a central organization or Mother Church became necessary. Therefore, in 1892, Mrs. Eddy with her followers founded the Christian Science Mother Church, The First Church of Christ, Scientist, in Boston, of which the local churches throughout the world are regarded as branches.

Mrs. Eddy passed away in 1910. Until then she had initiated every step in the progress of Christian Science. Nothing of moment was done without her approval. Furthermore, although the organic law of the Christian Science movement, its *Church Manual*, confers extensive and sufficient powers upon an administrative board, the Christian Science board of directors, yet this board always had functioned under her immediate supervision. Mrs. Eddy's demise, therefore, immediately tested the adequacy of the *Church Manual* as an organic law and the loyalty of Christian Scientists to this law, in the absence of its author. Nevertheless, the period since 1910 has been the most fruitful and prosperous in the history of Christian Science.

The theology of Christian Science begins with the propositions that God is the only might or Mind; that He is "the divine Principle of all that really is" (*Science and Health*, p. 275). To define God further, it employs frequently the word Good, besides such terms as Life, Truth, Love, Soul, Spirit and Infinite Person. Next to God, the name Jesus and references to him occur most frequently in the authorized literature of Christian Science. Concerning Jesus the Christ and his relation to God and men, Christian Science distinguishes between what is in the New Testament and what is in the creeds, doctrines and dogmas of later times. Accordingly, Christian Scientists speak of him oftenest as the Way or Way-shower and they regard his atonement, his chief work, as "the exemplification of man's unity with God, whereby man reflects divine Truth, Life and Love" (*Science and Health*, p. 18).

The most distinctive feature of Christian Science teaching is its absolute distinction between what is real and what is apparent or seeming but unreal. This distinction Mrs. Eddy explains, for instance, as follows: "All reality is in God and His creation, harmonious and eternal. That which He creates is good, and He makes all that is made. Therefore the only reality of sin, sickness

or death is the awful fact that unrealities seem real to human, erring belief, until God strips off their disguise. They are not true, because they are not of God" (*Science and Health*, p. 472). Contrary to common misapprehension, Christian Science does not ignore what it regards as unreal. This religion teaches its adherents to forsake and overcome every form of error or evil on the basis of its unreality; that is, by demonstrating the true idea of reality. This it teaches them to do by means of spiritual understanding, spiritual law and spiritual power.

In this connection, Christian Science maintains that the truth of being, the truth concerning God and man, includes a rule for its practice and a law by which its practice produces effects. To a certain extent Jesus declared this rule and law when he said, "Ye shall know the truth, and the truth shall make you free" (John viii, 32). Accordingly, for an individual to gain his freedom from any form of error or evil, he should know the truth, the absolute truth of being, applicable to his case; and Christian Science further teaches that this practice is effective when employed by one individual for another, because such is the unity of real being and such is the law of God. For these reasons, evidently Jesus could and did declare the possibility of Christian healing in unlimited terms. *See* Matthew x, 5–10, and xxviii, 16–20; Mark xvi, 14–18; John xiv, 12.

The practice of Christian Science is not merely mental; it must be also spiritual. Indeed, it is truly mental only as it is absolutely spiritual. The nonspiritual elements in the so-called human mind do not contribute to harmony or health. The practitioner must know or realize spiritually, and his ability to do this is derived from the divine Mind. Therefore, he must agree with the Teacher and Way-shower who said, "I can of mine own self do nothing" (John v, 30), and must prepare for the healing ministry and keep himself in condition for it by living the life of a genuine Christian. The practice of Christian Science is not limited, as is commonly supposed, to the healing of the sick. On the contrary, Christian Scientists regard their religion as applicable practically to every human need.

While the adherents of Christian Science are chiefly found among people who read English, it has followers among Christian people everywhere and also among Jews.

In Jan. 1950 there were 3,006 branches of the Mother Church, in addition to which there were 108 college and university organizations besides many groups not yet formally organized. Of these churches, there were in the United States 2,251; in Great Britain, 344; in Germany, 119; and in other countries, 292.

BIBLIOGRAPHY.—Mary Baker Eddy, *Science and Health, with Key to the Scriptures*, rev. ed. (1910); Edward A. Kimball, *Lectures and Articles on Christian Science* (1921); Charles Herman Lea, *A Plea for the Thorough and Unbiased Investigation of Christian Science* (London, 1923).

CHRISTIAN SOCIALISM is a term that has been used to denote a wide variety of social doctrines and movements which have attempted to give a basic, structural application to the social principles of Christianity. In the 19th century the term socialism in this context was employed in a loose sense, denoting, in opposition to *laissez-faire* individualism a Christian demand for some form of political or economic action in the interest of all the people. Christian Socialists usually did not demand the common ownership and control of the means of production and exchange. Roman Catholic Christian socialism, for example, promoted certain reforms to improve social relations, but its ultimate aim, in accord with papal encyclicals, was the establishment of a neofeudal corporative system, an order quite different from what is usually called socialism. In the 20th century, Christian social and industrial reform movements have been more and more referred to as the Christian social, the Protestant social or the Catholic social movement. The term Christian socialism tends to be reserved for those movements which attempt to combine the fundamental aims of socialism with the religious and ethical convictions of Christianity. It is this sort of Christian socialism that is mainly dealt with here.

Christian Socialism in England.—Although anticipations of Christian socialism are to be found in early Christian "communism of love" and in the radical sects of the middle ages, of the "left wing" of the Reformation and of the 17th century (*e.g.*, the Levellers in England), the term Christian socialism was first appropriated by the Broad Churchmen, J. F. D. Maurice, Charles Kingsley (the novelist), J. M. Ludlow and others, who entered on public propaganda immediately after the collapse of the chartist uprising of 1848. Their general purpose was to vindicate for "the Kingdom of Christ" its "true authority over the realms of industry and trade" and "for socialism its true character as the great Christian revolution of the 19th century." Four years after Karl Marx characterized religion as "opiate for the people," Kingsley (probably unaware of Marx's phrase) asserted that the Bible had been wrongly used as "an opium-dose for keeping beasts of burden patient while they were being overloaded" and as a "mere book to keep the poor in order" (in *Politics for the People*, 1848). Greatly stirred by the sufferings of the poor, the group vigorously criticized socially conservative Christianity and *laissez-faire* industrialism, extolling "the Bible principles" of self-sacrifice and co-operation as against self-interest and competition.

Reviving the co-operative movement, they favoured copartnership and profit-sharing in industry; they organized the Council for Promoting Working Men's Associations, which gave rise to or encouraged producers' and consumers' co-operatives; they aided in securing the enactment in 1852 of the Industrial and Provident Partnerships bill, the Magna Carta of the modern co-operative movement; and they instituted workers' education by founding the Working Men's college in London (1854). The movement as such continued for only a decade.

In 1877 Stewart Headlam founded the (Anglo-Catholic) Guild of St. Matthew, which espoused a composite of doctrines drawn from Maurice, from Tractarianism and from Fabian socialism. Somewhat similar if less definitely socialistic ideas gained influence after the turn of the century through the support of certain high churchmen who founded the Christian Social union (1889).

Subsequent to Headlam's effort numerous Christian Socialist organizations were formed, both in the established church and among the free churches. Prominent among these were the interdenominational Christian Socialist league, originating in the early 1880s, the labour churches (organized in 1891), and the (Anglican) Church Socialist league (founded in 1906), which emanated from the industrial north of England and brought the churches closer to labour and Socialist movements. Following internal dissension the Church Socialist league was succeeded in 1923 by the League of the Kingdom of God, which called for a generically Catholic Christian sociology looking toward the establishment of a neomediaeval social system. The (official Anglican) Industrial Christian fellowship, founded in 1919, was of a mediating character. The later (predominantly Free Church) Socialist Christian league and the (Anglo-Catholic) Order of the Church Militant made explicit demand for the communal control of the means of life and regarded socialism as the economic expression of Christianity. The Malvern declaration of 1941, drawn up by Anglicans under the leadership of Archbishop William Temple, was considered to be left-wing in character, but it was criticized for its "vagueness" by the Council of Clergy and Ministers for Common Ownership (founded in 1942). More sympathetic to Marxist philosophy was the (Free Church) Christian Left, which, under the leadership of John Macmurray, flourished in the 1930s and which viewed it to be "the religious mission of the working class to achieve Socialism."

Christian Socialism on the Continent.—The precursors of this movement on the continent are dealt with in another place. Roman Catholic Christian socialism (now called the Catholic social movement) was the first of its kind on the continent, but it was not socialistic except in the sense of a clerical socialism.

In France the Protestant Association for the Practical Study of Social Questions (founded in 1888) was mainly concerned with the need for social reform. T. Fallot, one of its principal found-

ers, opposed bourgeois, individualistic Protestantism and strove for a Protestant socialism that would achieve liberty through co-operation and through resisting an "artificial and deadly" equalitarian socialism. Until World War I, Protestant left-wing views were for the most part mildly social-reformist in character. In the 20th century Protestant Socialists found their most effective mediums of expression in the periodical *Le Christianisme Social* (founded in 1877), edited by Élie Gounelle, and in the Fédération du Christianisme Social. In this group one of the most influential Christian Socialists of the second quarter of the century was André Philip, an economist, a prolific writer on Christianity and socialism and a leader in labour and government circles.

Outstanding among German Protestant Christian Socialists in the 19th century were Rudolf Todt, Adolf Stöcker (who deviated into anti-Semitism), Friedrich Naumann and J. C. Blumhardt. The state Socialists Todt and Stöcker (anti-Marxist and in the throne and altar tradition) were, like the Catholic groups, opposed by the Social Democrats. Naumann took a more democratic attitude toward the worker and also believed it desirable for churchmen to co-operate with a revisionist social democracy. A still more favourable attitude toward social democracy was adopted by Blumhardt, who held that the Kingdom of God can be hindered by the churches and can be advanced by seemingly anti-Christian secular movements; indeed, he joined the Social Democratic party.

In the early part of the 20th century Hermann Kutter, "the Zürich Savonarola," held that the Social Democrats were revolutionary because God is; God's Kingdom must go forward in a revolutionary way despite, and even because of, the sluggishness of the churches. Leonhard Ragaz of Zürich, who looked forward to a Socialist society organized in freedom and love, was the connecting link with postwar movements in Switzerland and Germany. Christian socialism now assumed a great variety of forms. Some Christian Socialists (1) held that socialism is the logical consequence of Christianity, (2) others made socialism into a religion, (3) others tried to bring about understanding and interpenetration between the churches and the organized Socialist proletariat and (4) still others tried to uncover the roots of both Christianity and Marxist socialism toward the end of understanding more critically the affinities and the needed correctives. Representative of the fourth type was the League of Religious Socialists of south Germany, which included both Protestants and Catholics in its membership. Philosophically and theologically the most important and fruitful was the (Berlin) Kairos circle, which belonged to the fourth type mentioned and which for the decade preceding the nazi revolution was under the leadership of the theologian Paul Tillich. After 1933 Tillich went to the U.S., where his religious socialism exercised an influence.

Movements similar to the above-mentioned types have appeared also in other European countries; they were especially successful in the Scandinavian countries. Of intellectual significance in the 1930s and 1940s was the religious-Socialist "personalist" philosophy of the one-time Marxist, theosophical Russian Orthodox writer Nicolas Berdyaev, whose antecedents appear in the writings of 19th-century Russian lay theologians such as Theodore Dostoievski and Leo Tolstov.

Developments in America.—As the result of the absence of an archaic period in the history of the U.S., neofeudal and patriarchal forms of Christian socialism have played a small role; Puritan activism, the enlightenment and radical democratic tendencies have been more in evidence. Although ethical rationalism and deism exercised considerable influence in 18th-century religion and politics, although semi-Utopian Fourierist communities were established in the 1840s and 1850s and although progressive social concerns during this period found strong advocates in the Unitarians W. E. Channing, Joseph Tuckerman and Theodore Parker, a social Christianity was not widely expounded until after the Civil War. Its outstanding leaders down to the 1930s were R. H. Newton (an Episcopalian), Washington Gladden, Josiah Strong, G. D. Herron (Congregationalists), Shailer Mathews (a Baptist), Bishop Francis J. McConnell (a Methodist) and F. G. Peabody and J. H. Holmes (Unitarians). Of these men only Herron and Holmes were Socialists.

As early as 1849 Henry James, Sr., had argued the identity of the aims of Christianity and socialism. Largely under the leadership of W. D. P. Bliss, an Episcopalian who had been a member of the Knights of Labor, the Society of Christian Socialists was organized in 1889. Vigorously criticizing economic individualism and its ruinous progeny of plutocracy, industrial crises and wage slavery, the society attempted to show that "the aim of socialism is embraced in the aim of Christianity."

In the first quarter of the 20th century numerous Christian Socialist or quasi-Socialist groups were formed, as for example the nondenominational Christian Socialist fellowship (1906), the (pacifist) Fellowship of Reconciliation (started in England in 1914 and extended to the U.S. in 1915), the (Episcopalian) Christian Socialist league (1911–19), followed by the Church League for Industrial Democracy.

This period was the heyday of the Social Gospel movement, which, in the spirit of evolutionism and evangelical humanitarianism, interpreted the Kingdom of God as requiring social as well as individual salvation. Its most influential exponent was Walter Rauschenbusch (a Baptist), who demanded "a new order that would rest on the Christian principles of equal rights and democratic distribution of economic power." He distinguished sharply between the ultimate presuppositions of Christian socialism and those of secular socialism. Influences from this movement extended to Japan (*e.g.*, through T. Kagawa), China, South America and India.

Following World War I, Marxist doctrine and also radically democratic doctrine began to play a larger role. Harry F. Ward (a Methodist) and his disciples were moving toward a Christian Marxism which showed a marked sympathy with Russian communism. In the 1930s and 1940s a neo-Marxist and theologically neo-orthodox Christian socialism gained wide attention under the leadership of Reinhold Niebuhr (an Evangelical); attacking the "Utopian naturalism" of Marxism and the overoptimism of the "liberal" Social Gospel, the nondenominational Fellowship of Socialist Christians, founded in 1932, undertook a "Christian espousal of socialism" as the logical next step in a technical society; and the group published a magazine, *Christianity and Society*. The National Religion and Labor foundation (1932 *et seq.*), the Fellowship of Southern Churchmen (1934 *et seq.*) and the (Canadian) Fellowship for a Christian Social Order (1934 *et seq.*) advocated similar economic policies, as did the United Christian Council for Democracy (1936 *et seq.*) which provided a means of common action for the left-wing organizations of six liberal Protestant denominations. Beginning in 1939 *The Protestant Digest*, later named *The Protestant*, a journal edited by Kenneth Leslie (a Baptist), served as a medium of expression for Christian, Jewish and secular left-wing and neo-Marxist viewpoints. The Highlander Folk school (Monteagle, Tenn., 1932 *et seq.*) espoused a Christian Socialist gospel, co-operatives, unionism and adult education among rural and industrial workers. In most of these groups social planning tended to replace gradualist socialism as the remedy proposed for the ills of capitalism.

Although it has not been markedly successful in attracting the alienated working classes to the churches, Christian socialism has done much to stimulate churchmen to give a radical social application to Christian ethics in an industrial society.

CHRISTIANSUND, a seaport on the west coast of Norway, in Romsdal *amt* (county), 259 mi. N.E. by N. of Bergen, in the latitude of the Faeroe Islands. Pop. (1936) 14,646. It is built on four small islands, by which its harbour is enclosed. The chief exports before World War II were wood, cod, herrings and fish

products, and butter to Great Britain. The town is the chief port of the Nordmöre district. Till 1742, when it received town privileges from Christian VI, Christiansund was called Lille-Fosen.

CHRISTIAN UNITY: *see* REUNION, CHURCH.

CHRISTIE, RICHARD COPLEY (1830–1901), English scholar and bibliophile, was born on July 22, 1830, at Lenton, Notts., the son of a millowner. He was educated at Lincoln college, Oxford, was called to the bar at Lincoln's Inn in 1857 and in 1872 became chancellor of the diocese of Manchester. He resigned this position in 1893. He held numerous appointments, notably the professorships of history (from 1854 to 1856) and of political economy (from 1855 to 1866) at Owens college, Manchester. He always took an active interest in this college of which he was a governor; in 1893 he gave the Christie library building designed by Alfred Waterhouse, and in 1897 he devoted £50,000 of the funds at his disposal as trustee of Sir Joseph Whitworth's estate for the building of Whitworth hall, which completed the front quadrangle of the college. He was an enthusiastic book collector and bequeathed to Owens college his library of about 75,000 vol., rich in a complete set of books printed by Etienne Dolet, a wonderful series of Aldines, and of volumes printed by Sebastian Gryphius. His *Etienne Dolet, the Martyr of the Renaissance* (1880) is the most exhaustive work on the subject. He died at Ribsden on Jan. 9, 1901.

CHRISTIE, SIR WILLIAM HENRY MAHONEY (1845–1922), British astronomer, son of Samuel Hunter Christie, professor of mathematics at the royal military academy, Woolwich, was born at Woolwich on Oct. 1, 1845. He was educated at King's college school, London, and at Cambridge. In 1870 Christie was appointed chief assistant to Sir George Airy at the royal observatory, Greenwich, and in 1881 astronomer royal.

While Christie was at the observatory, the work was considerably extended, and it was largely because of him that regular spectroscopic and photographic observations were started. Some of these photographs form a valuable part of the work of the observatory, and the observations are still continued. Between 1890 and 1898 Christie supervised the construction of a new building and the erection of a 30-in. reflector and a 26-in. photographic refractor, enabling the observatory to take part in the international photographic map of the heavens; the measurements and publication of results occupied a number of years. Christie erected a wooden building for magnetic observations, designed a new altazimuth to replace a faulty one which had been used by Airy and also designed a "duplex" micrometer for identifying stars on overlapping plates. Christie wrote a number of papers embodying his work on the solar eclipses observed in Japan (1896), India (1898) and Portugal (1900), on the measurement of double stars, on the observations of Eros for determining the solar parallax and on the duration of exposure in photographing stars.

Christie received the C.B. on the occasion of Queen Victoria's Jubilee and the K.C.B. in 1904. He died on Jan. 22, 1922, while on a voyage to Mogador, Morocco, and was buried at sea.

CHRISTINA (MARIA CHRISTINA) (1858–1929), queen regent of Spain (1885–1902), widow of Alphonso XII and mother of Alphonso XIII, was born at Gross Seelowitz, Aus., on July 21, 1858, being the daughter of the archduke Charles Ferdinand and the archduchess Elizabeth of Austria. In 1879 she married Alphonso XII of Spain, whom she had met at the court of Vienna when he was only a pretender in exile, before the restoration of the Bourbons, and whose first wife, Mercedes, daughter of the duc de Montpensier, had died childless. Queen Christina bore her husband two daughters—Doña Mercedes, born on Sept. 11, 1880, and Doña Maria Theresa, born on Nov. 12, 1882. On her husband's death on Nov. 25, 1885, she became regent, and during the long minority of the posthumous son of Alphonso XII, later Alphonso XIII, she exhibited her wisdom, tolerance and unselfishness.

In spite of the excessive rotation of political parties under Práxedes Sagasta and Antonio Canovas del Castillo, the restlessness of the army, the economic depression and the disastrous war of 1898 with the United States, in which Spain renounced its rights over Cuba, Puerto Rico and the Philippines, the country, under Christina, won the respect of the great powers, and opposition from the former royal family gradually diminished. Her regency ended in 1902, when Alphonso XIII came of age.

Christina died Feb. 7, 1929.

CHRISTINA (1626–1689), queen of Sweden, daughter of Gustavus II and Marie-Eleonore of Brandenburg, was born at Stockholm, Swed., on Dec. 8, 1626. Her father was killed at Lützen (1632) when she was only six years old.

She was educated principally by the learned Johannes Matthiae, in as masculine a way as possible, while the chancellor, Count Axel Oxenstjerna, instructed her in politics. Christina became queen on her 18th birthday (Dec. 8, 1644). From the moment when she took her seat at the head of the council board she impressed her veteran counsellors with the conviction of her genius. Unfortunately her brilliant and commanding qualities were vitiated by an inordinate pride and egoism, which exhibited themselves in an utter contempt for public opinion, and a prodigality utterly regardless of the necessities of the state. She maintained a luxurious court, frequented by French artists, scholars and philosophers, and seemed to consider Swedish affairs as far too petty to occupy her full attention. Her unworthy treatment of the great chancellor was mainly caused by her jealousy of his extraordinary reputation. Recognizing that he would be indispensable as long as the Thirty Years' War lasted, she used every effort to bring it to an end; and her impulsive interference seriously hampered the diplomacy of the chancellor, and materially reduced the ultimate gain of Sweden. Yet she gave fresh privileges to the towns; she encouraged trade and manufactures, especially the mining industries of the Dales; in 1649 she issued the first school ordinance for the whole kingdom; she encouraged foreign scholars to settle in Sweden; and native science and literature, under her liberal encouragement, flourished as they had never flourished before. In one respect, too, she showed herself wiser than her wisest counsellors. The senate and the estates, naturally anxious about the succession to the throne, had repeatedly urged her majesty to marry, and had indicated her cousin, Charles Gustavus, as her most fitting consort. Wearied of their importunities, Christina settled the difficulty by appointing Charles her successor, and at the *riksdag* of 1650 the Swedish crown was declared hereditary in Charles and his male heirs.

In the summer of 1651 Christina was, with difficulty, persuaded to reconsider her resolution to abdicate, but three years later the nation had become convinced that her abdication was highly desirable.

There were many causes which predisposed her to what was, after all, anything but an act of self-renunciation. First of all she could not fail to remark the increasing discontent with her arbitrary and wasteful ways. Within ten years she had created 17 counts, 46 barons and 428 lesser nobles; and, to provide these new peers with adequate appanages, she had sold or mortgaged crown property representing an annual income of 1,200,000 rix-dollars. Signs were also not wanting that Christina was growing weary of the cares of government, while the importunity of the senate and *riksdag* on the question of her marriage was a constant source of irritation. From 1651 there was a notable change in her behaviour. She cast away every regard for the feelings and prejudices of her people. She ostentatiously exhibited her contempt for the Protestant religion. Her foreign policy was flighty to the verge of foolishness. She contemplated an alliance with Spain, a state quite outside the orbit of Sweden's influence, the first fruits of which were to have been an invasion of Portugal.

She utterly neglected affairs in order to plunge into a whirl of dissipation with foreign favourites. The situation became impossible, and it was with an intense feeling of relief that the Swedes saw her depart, in masculine attire, under the name of Count Dohna. At Innsbruck she openly joined the Catholic Church, was rechristened Alexandra and kept up a royal household in Rome, surrounded by cardinals. In 1656, and again in 1657, she visited France, on the second occasion ordering the assassination of her major-domo, Giovanni Monaldischi, for continuous betrayal of her confidence.

Twice she returned to Sweden (1660 and 1667) in the vain

hope of recovering the succession, finally settling in Rome, where she died on April 19, 1689, poor, neglected and forgotten.

Gribble, *The Court of Christina of Sweden* (1913), *The History of the Intrigues and Gallantries of Christina, Queen of Sweden, and of Her Court Whilst She Was at Rome*, Eng. trans. by P. Hollingworth (1697; repr. 1927).

CHRISTISON, SIR ROBERT, BART. (1797–1882), Scottish toxicologist and physician, was born in Edinburgh on July 18, 1797. He studied in London under John Abernethy and Sir William Lawrence, and in Paris under Pierre J. Robiquet and M. J. B. Orfila. In 1822 he became professor of medical jurisprudence at Edinburgh. In 1829 his *Treatise on Poisons* was published, and he became medical officer to the crown in Scotland, and from that time till 1866 he was called as a witness in many celebrated criminal cases, notably in the case of William Burke and William Hare (1829). Instructions drawn up by him for the examination of dead bodies for legal purposes became the accepted guide for the purpose. He may be said to have placed legal jurisprudence on a scientific basis. In 1832 he gave up the chair of medical jurisprudence for that of medicine and therapeutics, which he held till 1877. His work on the pathology of the kidneys and on fevers brought him many honours, including a baronetcy in 1871. Christison died at Edinburgh on Jan. 23, 1882.

See *The Life of Sir Robert Christison* (1885–86), edited by his sons, which contains his autobiography, with chapters on his work by Gairdner and T. R. Fraser.

CHRISTMAS (*i.e.*, the mass of Christ), in the Christian Church, the festival of the nativity of Jesus Christ. The history of this feast coheres so closely with that of Epiphany (*q.v.*), that what follows must be read in connection with the article under that heading.

Origin.—Christmas was not among the earliest festivals of the church, and before the 5th century there was no general consensus of opinion as to when it should come in the calendar, whether on Jan. 6, March 25 or Dec. 25. The earliest identification of Dec. 25 with the birthday of Christ is in a passage, otherwise unknown and probably spurious, of Theophilus of Antioch (*c.* 180), preserved in Latin by the Magdeburg centuriators (i, 3, 118), to the effect that the Gauls contended that since they celebrated the birth of the Lord on Dec. 25, they ought to celebrate the resurrection on March 25. A passage, almost certainly interpolated, in Hippolytus' (*c.* 202) commentary on Daniel iv, 23, says that Jesus was born at Bethlehem on Wednesday, Dec. 25, in the 42nd year of Augustus, but no feast is mentioned, and such a feast, indeed, would conflict with the then orthodox ideas. As late as 245 Origen (hom. viii on Leviticus) repudiated the idea of keeping the birthday of Christ, "as if he were a king Pharaoh."

The first certain mention of Dec. 25 is in the calendar of Philocalus (354), which was first published entire by Theodor Mommsen in *Abhandlungen d. sächs. Akad. d. Wissensch.* (1850), and is dealt with in Joseph Strzygowski's *Kalenderbilder des Chron. vom Jahre 354* (1888). This states that in "Year 1 after Christ the Lord Jesus Christ was born on Dec. 25, a Friday, and 15th day of the new moon"—though, in fact, Dec. 25, A.D. 1, was a Sunday. Here again no festal celebration of the day is attested.

Clement of Alexandria (*c.* 200) mentions several speculations on the date of Christ's birth, and condemns them as superstitious. Some chronologists, he says, alleged the birth to have occurred in the 28th year of Augustus, on 25 Pachon (an Egyptian month); *i.e.*, May 20. Others assign it to 24 or 25 Pharmuthi (April 19 or 20). Clement himself sets it on Nov. 17, 3 B.C.; and the anonymous author of a Latin tract, *De Pascha computus* (written in Africa, 243), sets it, "by private revelation," on Wednesday, March 28, the supposed anniversary of the creation of the sun, which typifies the Sun of Righteousness.

Similar symbolical reasoning led Polycarp (in a fragment preserved by an Armenian writer, Ananias of Shirak, dated before 160) to set His birth on Sunday, when the world's creation began, but His baptism on Wednesday, as the analogue of the sun's creation. On such grounds certain Latins as early as 354 may have transferred the birthday from Jan. 6 to Dec. 25, which was then a Mithraic feast, the *natalis invicti solis* or birthday of the unconquered Sun of Philocalus. The Syrians and Armenians, who clung to Jan. 6, accused the Romans of sun worship and idolatry, contending that the feast of Dec. 25 had been invented by disciples of Cerinthus and its lections by Artemon to commemorate the *natural* birth of Jesus. Ambrose (*On Virgins*, iii, ch. 1) seems to imply that as late as the papacy of Liberius (352–356) the birth was feasted together with the marriage at Cana and the "feeding of the four thousand," which were never feasted on any other day but Jan. 6.

Chrysostom, in a sermon preached at Antioch on Dec. 20, 386 or 388, says that the feast of Dec. 25 was known in the west, from Thrace as far as Cadiz, from the beginning. It certainly originated in the west, but spread quickly eastward. In 353–361 it was observed at the court of Constantius; Basil of Caesarea (d. 379) adopted it; Honorius, emperor (395–423) in the west, told his mother and brother Arcadius (395–408) in Byzantium how the new feast was kept in Rome, separate from Jan. 6 with its own *troparia* and *sticharia;* and they adopted it. The patriarchs Theophilus of Alexandria, John of Jerusalem and Flavian of Antioch were won over to it under Pope Anastasius, 398–401. John or Wahan of Nice (Combefis, *Historia monothelitarum*) affords the above details. The new feast was communicated by Proclus, patriarch of Constantinople, to Sahak, Catholicos of Armenia, about 440; and the Armenians within the Byzantine pale adopted it for about 30 years, but finally abandoned it, together with the decrees of Chalcedon, early in the 8th century. Many writers of the period 375–450 (*e.g.*, Epiphanius, Cassian, Asterius, Basil, Chrysostom and Jerome) contrast the new feast with that of the baptism as that of the birth *after the flesh*, implying that the latter was generally regarded as a birth according to the spirit. Hermann Usener notes that in 387 the new feast was reckoned according to the Julian calendar by writers of the province of Asia, who in referring to other feasts use the reckoning of their local calendars. As early as 400 in Rome an imperial rescript includes Christmas (with Easter and Epiphany) among the three feasts on which theatres must be closed. Epiphany and Christmas were not made judicial *non dies* until 534.

For some years in the west (as late as 353 in Rome) the birth feast was appended to the baptismal feast on Jan. 6 and was altogether supplanted by it in Jerusalem from about 360 to 440, when Bishop Juvenal introduced the feast of Dec. 25, which about the same time was finally established in Alexandria. The *quadragesima* of Epiphany (*i.e.*, the presentation in the Temple) continued to be celebrated in Jerusalem on Feb. 14 until the reign of Justinian. In most other places it had long before been put back to Feb. 2 to suit the new Christmas. But in Jerusalem, as Armenian historians record, the transference occasioned riots.

In Britain, Dec. 25 was a festival long before the conversion to Christianity, for Bede (*De temp. rat.*, ch. 13) relates that "the ancient peoples of the Angli began the year on Dec. 25 when we now celebrate the birthday of the Lord; and the very night which is now so holy to us, they called in their tongue *modranecht* (*môdra niht*), that is, the mothers' night, by reason we suspect of the ceremonies which in that night-long vigil they performed." In England the observance of Christmas was forbidden by act of parliament in 1644; Charles II revived the feast, but the Scots adhered to the Puritan view. Outside Teutonic countries Christmas presents are unknown. Their place is taken in Latin countries by the *strenae*, French *étrennes*, given on New Year's day. The setting up in Latin churches of a Christmas crèche is said to have been originated by St. Francis.

(X.)

Christmas Customs.—Christmas customs are an evolution from times that long antedated the Christian period—a descent from seasonal, pagan, religious and national practices, hedged about with legend and tradition. Their seasonal connections with the pagan feasts of the winter solstice relate them to the beginning of time and their legacy in the birthday of Christ makes them shareholders in the most significant event in the history of

the world—an event that gave it a new date, anno Domini.

In the beginning many of the earth's inhabitants were sun worshippers because the course of their lives depended on its yearly round in the heavens, and feasts were held to aid its return from distant wanderings. In the south of Europe, in Egypt and Persia, the sun gods were worshipped with elaborate ceremonies at the season of the winter solstice, as a fitting time to pay tribute to the benign god of plenty, while in Rome the Saturnalia reigned for a week. In northern lands mid-December was a critical time, for the days became shorter and shorter and the sun was weak and far away. Thus these ancient peoples held feasts at the same period that Christmas is now observed; they built great bonfires in order to give the winter sun god strength and to bring him back to life again. When it became apparent that the days were growing longer, there was great rejoicing because of the promise of lengthening days to follow. Thus, the central idea of the winter solstice—the return of light—became the hope of the world in the birth of Christ, the light of the world.

The exact day and year of Christ's birth have never been satisfactorily settled, but when the fathers of the church in A.D. 440 decided upon a date to celebrate the event, they wisely chose the day of the winter solstice which was firmly fixed in the minds of the people and which was their most important festival. Because of changes in man-made calendars, the time of the solstice and the date of Christmas vary by a few days.

The transition from paganism to Christianity was gradual but became apparent after the fall of Rome (A.D. 476) when the church was the one organization which had the strength and wisdom to withstand the disorganized centuries of the dark ages. During this time great progress was made by the Christian leaders in extending the new faith.

When missionaries were sent from Rome to the outlying provinces in 601, their instructions given by Pope Gregory I made clear the policy of the church: "Let the shrines of idols by no means be destroyed but let the idols which are in them be destroyed. Let water be consecrated and sprinkled in these temples: let altars be erected . . . so that the people, not seeing their temples destroyed, may displace error, and recognize and adore the true God. . . . And because they were wont to sacrifice oxen to devils, some celebration should be given in exchange for this . . . they should celebrate a religious feast and worship God by their feasting, so that still keeping outward pleasures, they may more readily receive spiritual joys." (Bede, *Ecclesiastical History of the English Nation.*)

For several centuries Christmas was solely a church anniversary observed by religious services. But as Christianity spread among the people of pagan lands, many of the practices of the winter solstice were blended with those of Christianity because of the liberal ruling of Gregory I, the Great, and the co-operation of the missionaries.

Thus, Christmas became both religious and secular in its celebration, at times reverent, at others gay. From the pagan accent on light it is not difficult to trace the rise of lights and open fires —from the bonfires of sun worship and their variant, the yule log, to the many customs centring around the candle and its legends to light the Christ child.

Many customs besides those of light and fire date back in some way to these pre-Christian origins, among them Christmas decorations. The Romans ornamented their temples and homes with green boughs and flowers for the Saturnalia, their season of merrymaking and the giving of presents; the Druids gathered mistletoe with great ceremony and hung it in their homes; the Saxons used holly, ivy and bay.

It is generally believed that the first Christmas tree was of German origin dating from Boniface, English missionary to Germany in the 8th century, who replaced the sacrifices to Odin's sacred oak by a fir tree adorned in tribute to the Christ child. Accounts persist that Martin Luther introduced the tree lighted with candles. It is known that the German prince Albert, soon after his marriage to Queen Victoria, introduced it into England, and that German immigrants brought the custom to the United States.

Music early became a marked feature of the season. But the first chants, litanies and hymns were in Latin and too theological for popular use. The 13th century found the rise of the carol written in the vernacular under the influence of Francis of Assisi: carol meaning a song in which a religious topic is treated in a style that is familiar or festive. From Italy, it passed to France and Germany, and later to England, everywhere retaining its simplicity, fervour and mirthfulness. Music in itself has become one of the greatest tributes to Christmas, and includes some of the noblest compositions of the great musicians, especially George Frederick Handel's *Messiah* with its "Hallelujah Chorus."

Anthems sung by choirs with organ accompaniment and hymns and carols sung by the congregation constitute modern Christmas church music. As a setting for the music and services of the Protestant churches, evergreen trees and branches and other seasonal decorations transform the church, pulpit and choir loft, combining thus the details of customs that have evolved with the centuries.

In Roman Catholic churches the heart of the celebration is the crèche, or crib, the realistic tableau in miniature of the nativity, another custom introduced in an Italian church by Francis of Assisi in 1224, in his efforts to bring Christmas to the people. The secular singing of folksongs and carols on the Christmas theme by minstrels and waits was customary, especially in England. House-to-house singing survives in many communities.

In keeping with the religious significance of Christmas, the church, as early as the 6th century, set apart the four Sundays preceding Christmas as a time of devotional preparation, known as the Advent season, which ends with Christmas eve. From this date on, the Catholic Church held a midnight mass as one of the solemnities of Christ's birthday. Equally solemn is the Christmas morning service in Lutheran churches, especially the Swedish; the service was put at an early hour by the Lutherans because the shepherds, the first to worship Him, came early and then returned to their work.

Merrymaking came to have a share in Christmas observance through popular enthusiasm even while emphasis was on the religious phase. The mediaeval secular celebrations were no matter of a day or two but lasted for a season extending from Christmas eve to Epiphany, and in some localities even longer, from St. Thomas' day to Candlemas. In England Christmas became increasingly the great festival of the year from the 11th to the 17th centuries, with observance from Christmas eve to Twelfth day. In the holly-decked great halls of the feudal lords, whose hospitality extended to all their friends, tenants and household, wassailing, feasting, singing and games, dancing, masquerading, mummers presenting pantomimes, and masques were all part of the festivities. A lord of misrule and his jester directed the revels and kept them uproarious, from the dragging in of the yule log to the end of the holiday. The Christmas feast, brought in state into the hall, heralded by the lord of misrule and the minstrels headed by the chief cook carrying the boar's head followed by the servants bearing an incredible number of dishes, was the outstanding event. But the wild licence of these celebrations, with no semblance of the inner vision and meaning of Christmas, came under the disfavour of the Puritans and were forbidden by parliament in 1644, after the Puritans came into power.

England gradually found Christmas again and made it both a church ceremonial and a home festival. There are family reunions, gifts, decorations, carols and parties, and a pantomime for the children, whose day it is and for whom Father Christmas, the English counterpart of Santa Claus, was introduced. It is a season of good will with much hospitality, roast goose and plum pudding being associated with the day. The true spirit of the day prevails, as set forth in the immortal *A Christmas Carol* by Charles Dickens, written in the year 1843.

Although many of the picturesque customs were suppressed, they have contributed vicariously to modern observance through Christmas pageants, in the designs of Christmas cards and favours and in adapted formalities of social functions. Descriptive accounts and crude drawings found in old household or day books and other chronicles, together with the narratives in ballads and

carols, have aided in this artistic restoration, keeping the old English Christmas always present.

The Scandinavian countries have always had a natural tendency for the keeping of Christmas, because of the northern location and their winter solstice traditions; they have transplanted their customs wherever they have settled. Elaborate preparations are begun weeks in advance, and there is a great amount of cooking of special meats and baking of breads, fancy cakes, cookies and other special foods.

Germany has also kept Christmas with much heartiness in the old manner with emphasis on home celebrations and attendance at church services. The observance centres around the Christmas tree, and carols include "O Tannenbaum" and "Stille Nacht."

In the Netherlands and Belgium the feast of St. Nicholas, Dec. 6, is the children's holiday, when the customs associated with Christmas and feasting are observed. Dec. 25 is a religious holiday, with services in the churches and quiet family gatherings at home, where Christmas cakes and other favours are served. One of the traditions of Christmas is Santa Claus, a contraction for St. Nicholas who was born in the 3rd century; he became a bishop and gained distinction in the councils of the church, being especially famed for unexpected gifts, and later associated with the giving of presents during the season at the end of the year. He seems to have been first adopted by the Netherlands as the patron saint of children, and there, on St. Nicholas eve, they leave their wooden shoes, filled with hay for the saint's white horse. He is real to children the world over, under such various names as Kris Kringle, La Befana, Yule Tomten and Christkindli.

New Year's day came to be the great festival in France and Scotland, many of the Christmas customs being observed on that day. The religious features are prominent in France, especially the crèche in churches and homes and the midnight mass followed by elaborate Christmas suppers. The Feast of the Kings, or Epiphany, finishes the holiday season with traditional parties.

The Italian Christmas is a sacred holiday, observed with solemn ceremonies including a midnight mass in the churches. Though there are home customs and special foods, gifts are reserved for Epiphany.

The *Presepio*, or miniature representation of the nativity, rather than the Christmas tree, came to be the holiday symbol in Italian homes.

Christmas in the United States, composed of threads from many countries and reflecting their customs in church and home, has evolved into a celebration that is more or less uniform, with some variations according to sections and origins, such as those of the Pennsylvania Germans in Bethlehem and the Scandinavians in Wisconsin and Minnesota. The festive aspects were not accepted in New England until about 1875, because of Puritan influence.

For generations Christmas customs have focused around the fact that it belongs to the season of frost and snow. Transplanted to a tropical climate, its celebration would, of course, be different in many ways.

In tropical Mexico, where Roman Catholicism is the state religion, every home is decorated with flowers and has an altar erected with a representation of the nativity, in preparation for the *Posadas*. This means "resting place" and commemorates the journey Mary and Joseph took from Nazareth to Bethlehem. The *Posadas* begin on Dec. 16, and groups of nine families hold one every night before Christmas eve, meeting in the different homes. Carrying candles and following an image of the Virgin and Joseph; they re-enact the search for shelter, stopping at the door of each room and pleading for entry. In the last room they are admitted and there sing their thanks.

Christmas in Brazil, for example, falls in midsummer, giving it the characteristics of a summer festival with flowers for decorations, fireworks, picnics, fiestas and boating excursions. The religious phase is the same as in other Catholic countries, with a *Presepio* in homes and churches; the midnight mass, with an out-of-door procession of the priests to the church, is a colourful part of the festival. Family suppers are served on Christmas eve; the people hold carnivals in the streets, and everywhere there is much gaiety. Various customs brought by people from the United States have crept in, including Papa Noel, dressed like Santa Claus. Both Christmas and King's day, as Epiphany is called, serve as gift-giving occasions.

CHRISTMASBERRY (*Photinia arbutifolia*), a handsome American shrub or small tree of the rose family (Rosaceae), called also California holly and toyon, native chiefly to the chaparral (*q.v.*) belt of the Sierra Nevada and coast ranges.

It grows from 5 to 15 ft. high and bears oblong, pointed, evergreen leaves and numerous small, white flowers in large, terminal clusters, followed in late autumn by bright red, hollylike fruits. It is very popular for Christmas decoration, being sold in Pacific coast cities in the same manner as holly in the eastern United States.

CHRISTMAS ROSE: *see* HELLEBORE.

CHRISTODORUS, of Coptos in Egypt, epic poet, flourished during the reign of Anastasius I (A.D. 491–518). According to Suidas, he was the author of Ἱάτρια, accounts of the foundation of various cities; Ὑδιακά, the mythical history of Lydia; Ἰσαυρικά, the conquest of Isauria by Anastasius; three books of epigrams; and many other works.

In addition to two epigrams (*Anthol. Pal.*, vii, 697, 698) we possess a description in hexameters of 80 statues in the gymnasium of Zeuxippus at Constantinople; this forms the second book of the Palatine anthology. Some critics regard it as important for the history of art and a model of description; others consider it valueless.

See F. Baumgarten, *De Christodoro poëta Thebano* (1881), and his article in Pauly-Wissowa's *Realencyklopädie*, iii, 2 (1899); W. Christ, *Geschichte der griechischen Literatur* (1898).

CHRISTOPHE, HENRY (1767–1820), Negro king of Haiti. After purchasing his freedom from slavery he played a prominent part in the insurrection against the French and in the rising of 1803. He was general in chief of the army during the short-lived government of Jean Jacques Dessalines. Appointed president of Haiti in 1807, after the ensuing civil war, he was crowned king on June 2, 1812.

Under him the country prospered, but his cruelty led to an insurrection, and being deserted by his troops, he shot himself on Oct. 8, 1820. (*See* HAITI: *History*.)

See J. Vandercook, *Black Majesty* (1928).

CHRISTOPHER, SAINT (CHRISTOPHORUS, CHRISTOFERUS), patron saint of ferrymen, is honoured in the Latin Church on July 25 and in the Greek Church on May 9. He appears to have been born a pagan in Syria, to have been baptized by Babylas, bishop to Antioch; he preached in Lycia and was martyred *c.* A.D. 250 during the persecution under the emperor Decius. The more conspicuous of the legends which collected about this nucleus of possibility are included in the Mozarabic *Breviary* and *Missal*, the best known being given in the *Golden Legend* of Jacopus de Voragine. According to this, Christopher was a giant in search of a master stronger than himself. He left the service of the king of Canaan because the king feared the devil, and that of the devil because the devil feared the Cross. He was converted by a hermit; but since he had neither the gift of fasting nor that of prayer, he decided to devote himself to a work of charity, and set himself to carry wayfarers over a bridgeless river.

One day a little child asked to be taken across, and Christopher took him on his shoulders. When halfway over the stream, he staggered under what seemed to him a crushing weight; but he reached the other side and then upbraided the child for placing him in peril. "Had I borne the whole world on my back," he said,

"it could not have weighed heavier than thou!" "Marvel not!" the child replied, "for thou hast borne upon thy back the world and Him who created it!"

CHRISTOPHORUS, pope or anti-pope, elected in 903 against Leo V, whom he imprisoned. In Jan. 904 he was treated in the same fashion by his competitor, Sergius III, who had him strangled.

CHRISTOPOULOS, ATHANASIOS (1772–1847), Greek poet, was born at Castoria in Macedonia. He studied at Buda and Padua, and became teacher of the children of the Vlach prince Mourousi. After the fall of Mourousi in 1811 he was employed by Prince Caradja, hospodar of Moldavia and Walachia, in drawing up a code of laws for that country. On the removal of Caradja, he retired into private life and devoted himself to literature. He wrote drinking songs and love ditties which are very popular among the Greeks. He also wrote *Politika Parallela* (a comparison of various systems of government), translations of Homer and Herodotus, a tragedy and some philological works on the connection between ancient and modern Greek.

His *Hellenika Archaiologemaia* (Athens, 1853) contains an account of his life.

CHRIST'S HOSPITAL (the BLUE COAT SCHOOL) was originally one of three royal hospitals in the city of London, founded by Edward VI. Christ's hospital was specially devoted to fatherless and motherless children. The buildings of the monastery of Grey Friars, Newgate street, were appropriated to it; liberal public subscription added to the king's grant endowed it richly, and the mayor, commonalty and citizens of London were nominated its governors in its charter of 1552. Not long after its opening Christ's was providing home and education (or, in the case of the very young, nursing) for 400 children. The popular name of the Blue Coat school is derived from the dress of the boys—originally (almost from the time of the foundation) a blue gown, with knee breeches, yellow petticoat and stockings, neckbands and a blue cap. The petticoat and cap were given up in the middle of the 19th century. In 1902 the buildings on the Newgate street site were vacated by the school, which was moved to new buildings at Horsham. It includes a preparatory school for boys, established in 1683 at Hertford, where the buildings have been enlarged for the use of the girls' school on the same foundation.

CHRISTUS, PETRUS (d. 1472/73), Flemish painter, born at Baerle in Brabant, in 1444 acquired citizenship rights at Bruges, where he worked until his death. Following the example of Jan van Eyck, he added a date and signature, usually in the form "PETRUS XPI," to some of his pictures. These include "Edward Grymeston," 1446 (earl of Verulam's collection), "A Carthusian," 1446 (New York), "St. Eligius," 1449 (New York, Lehman coll.), "Virgin and Child," 1449 (Lugano, Thyssen coll.), altar wings with "Annunciation," "Nativity" and "Last Judgment," 1452 (Berlin) and the "Virgin With SS. Jerome and Francis," probably 1457 (Frankfurt). Among others ascribed to him are two versions of the "Nativity" (Washington, D.C.; New York, Wildenstein), three versions of the "Lamentation Over the Dead Christ" (Brussels; New York; Paris), the "Virgin With a Carthusian" (Berlin) and two portraits (Berlin; London).

Christus appears as the closest of Jan van Eyck's followers, yet some of his motifs and compositions show that he was no stranger to the different tradition exemplified by the Master of Flémalle and Rogier van der Weyden. These borrowings from more powerful spirits tend to overshadow and confuse his personal development. Compared with Van Eyck's all-seeing eye or with Rogier's emotional force his pictures seem empty, conventional and phlegmatic. Nevertheless, they remain admirable for their careful construction and jewellike execution. The Frankfurt "Virgin With Saints" is the earliest Netherlandish picture with a single vanishing point.

See W. H. J. Weale, *Peintres Brugeois: les Christus* (Bruges, 1909); M. J. Friedländer, *Die Altniederländische Malerei*, vol. i (Berlin, 1924), xiv (Berlin, 1937). (D. Ku.)

CHRISTY, HENRY (1810–1865), English ethnologist, was born at Kingston-on-Thames, Eng., on July 26, 1810. From 1850–58 he travelled in Europe and America, studying ethnology. In 1858 the discoveries by Boucher de Perthes of flint implements in France and England were first held to have proved the great antiquity of man. Christy joined the Geological society, and with his friend Edouard Lartet explored the caves in the valley of the Vézère. An account of the explorations appeared in *Comptes rendus* (Feb. 29, 1864) and *Transactions of the Ethnological Society of London* (June 21, 1864). He died, on May 14, 1865, leaving a half-finished book, entitled *Reliquiae Aquitanicae*, which was issued in parts and completed first by Lartet and, after the latter's death in 1870, by Rupert Jones. Christy's archaeological collection was placed in the British Museum in 1884.

CHROMATES AND DICHROMATES: *see* CHROMIUM.

CHROMATIC, a term meaning "coloured," used in science, particularly in the expression "chromatic aberration" or "dispersion" (*see* ABERRATION OF LIGHT). In Greek music χρωματική μουσική was one of three divisions—diatonic, chromatic and enharmonic—of the tetrachord. Like the Latin *color*, χρῶμα was often used of ornaments and embellishments, and particularly of the modification of the three *genera* of the tetrachord. The chromatic, being subject to three such modifications, was regarded as particularly "coloured." To the Greeks chromatic music was sweet and plaintive. From a supposed resemblance to the notes of the chromatic tetrachord, the term is applied to a succession of notes outside the diatonic scale, and marked by accidentals. A "chromatic scale" is thus a series of semitones.

CHROMATOMETER or TINTOMETER, an instrument for standardizing the *intensity* and *hue* of a given colour (*q.v.*). The specimen is compared with a standard by viewing the two simultaneously and interposing in front of the standard various standard coloured plates until a match is obtained. Instead of the plates, strata liquids of the three primary colours may be used. (*See* also COLORIMETER.)

CHROME STEEL: *see* IRON AND STEEL; STAINLESS STEEL.

CHROMITE, a member of the spinel group of minerals; an oxide of chromium and ferrous iron, $FeCr_2O_4$. It is the chief commercial source of chromium and its compounds. It crystallizes in regular octahedra, but is usually found as grains or as granular to compact masses. In its iron-black colour with submetallic lustre and absence of cleavage it resembles magnetite (magnetic iron ore) in appearance, but differs from this in being only slightly, if at all, magnetic and in the brown colour of its powder. The hardness is 5½; specific gravity, 4.5. The theoretical formula $FeCr_2O_4$ corresponds with chromic oxide (Cr_2O_3) 68%, and ferrous oxide 32%; the ferrous oxide is, however, usually partly replaced by magnesia, and the chromic oxide by alumina and ferric oxide, so that there may be a gradual passage to picotite or chrome spinel. Much of the material mined as ore does not contain more than 40% to 50% of chromic oxide. The earliest-worked deposits of chromite were those in the serpentine of the Bare hills near Baltimore, Md. The principal producing areas of chromite are, in the order of their importance, Southern Rhodesia, U.S.S.R., Turkey, Union of South Africa, Philippines, Cuba, Yugoslavia, India, Greece and New Caledonia. Chrome ore is used in manufacturing special steels and alloys, as a metallurgical refractory and in manufacturing chemicals. Chemical uses include dyeing, tanning and for pigments. (W. F. Fg.)

CHROMIUM is a metallic chemical element, called so from the Greek χρῶμα, colour, because of the varied colours of its compounds. In 1798 L. N. Vauquelin and M. H. Klaproth simultaneously and independently discovered a new element in addition to lead in the mineral crocoisite or crocoite (lead chromate, $PbCrO_4$) first described by J. G. Lehmann in 1762. The metal was not isolated, however, until 1859, when F. Wöhler obtained small quantities of it by reduction of the trichloride with potassium. Because of the difficulty of reduction and of electrodeposition, the metal remained a chemical curiosity for many decades, although it was in 1950 produced on a large scale for use in stainless and alloy steels. Its symbol is Cr, and it has an atomic number of 24 and an atomic weight of 52.01.

Stable isotopes of the following mass numbers are known: 50 (4.49%), 52 (83.77%), 53 (9.43%), 54 (2.30%) and the artificially radioactive isotopes 51 (half life 26.5 days) and 55 (2.3 hr.). The distribution of the 24 electrons in the various quantum groups, $1s^2$, $2s^2$, $2p^6$, $3s^2$, $3p^6$, $3d^5$, $4s^1$, is indicated by the superscripts. The valence electrons are in the $3d$ and $4s$ states and thus are 6 in number.

Occurrence and Production.—Igneous rocks contain on the average 0.037% chromium, usually as compounds of Cr_2O_3. The metal is not found free in nature. The principal commercial ore is chromite, $FeCr_2O_4$ or $FeO.Cr_2O_3$. The world production of crude chromite (approximately 50% Cr_2O_3) was 1,744,000 metric tons in 1943 and the five largest producing countries were: Cuba (354,152 tons), U.S.S.R. (325,000 tons), Southern Rhodesia (266,272 tons), Turkey (196,836 tons) and Union of South Africa (163,232 tons). In addition to chromite and crocoisite, chromium is also found as sesquioxide in chrome ochre, Cr_2O_3, as potassium chromate, K_2CrO_4, as redingtonite (a hydrated sulphate), as phosphochromates, as basic chromates, as ferrous thiochromite, $Fe(CrS_2)_2$, and in various other combinations. The green colour of emerald, serpentine, chrome mica and chrome garnet is due to chromium, as is also the red colour of ruby, and some sapphires and spinels.

Metallurgy and Uses.—In the metallurgy of the element, chromite is usually reduced to ferrochrome, $FeCr_2O_4+4C=Fe+2Cr+4CO$. Low chrome steel contains 0.5% to 1% of Cr which increases the hardness and tensile strength. Stainless steel (6%–30% Cr) is very resistant to chemical oxidation and is widely used in the manufacture of cutlery, turbine blades and apparatus for the chemical industries. These steels are generally made by the addition of ferrochrome to steel scrap in an electric furnace, but some are made directly in the open-hearth furnace. Other alloys are nichrome (60% Ni, 15% Cr and 25% Fe), used as resistance wire, and stellite (60% Co, 15% Cr, 20% W and 5% Mo), employed for high-speed cutting tools. Chrome plating on steel or copper has become highly important in the automobile industry. The metal cannot be deposited from pure chromic-acid solutions, but the electrolytic deposition proceeds if a high concentration of sulphate as chromic sulphate or sulphuric acid is present. The metal may also be prepared by the Goldschmidt process in which the sesquioxide is reduced by aluminum. The distillation of chromium amalgam at 350° C. in hydrogen yields a pyrophoric (spontaneously inflammable) powder form of the metal. A large fraction of the chromite production is used in the manufacture of refractory chrome bricks for lining metallurgical furnaces. Among the more important chromium pigments are: chrome oxide green, Cr_2O_3, a highly stable pigment; zinc yellow, a basic potassium zinc chromate, used as a corrosion inhibitor; chrome orange, basic lead chromate, similar use; and chrome yellow, lead chromate, used in paints and printing ink. The most important commercial salt is sodium dichromate, $Na_2Cr_2O_7$. It may be prepared by fusing the ore with sodium carbonate in air and extracting with dilute acid. Chrome tanning is in general use in the leather industry. In one method, the hides are first treated with a weak acidified bath of sodium dichromate. The hides are then transferred to a second bath containing an acid solution of sodium thiosulphate which reacts to form basic chromic sulphates and rapidly converts the hide into leather.

Properties.—Chromium is a steel-white metal, harder than iron, cobalt or nickel, and capable of taking a brilliant polish. It is nonmagnetic at ordinary temperatures, but becomes magnetic at −15° C. The melting point is 1,900° C. and the boiling point 2,482° C., the melting point being higher than that of manganese, iron, cobalt or nickel, though the boiling point is less than that of any of these. The density of the metal varies from 6.7 to 7.1. The electrolytically deposited metal occludes about 250 times its volume of hydrogen. It has a normal body centred crystal structure at room temperature, but a hexagonal and a complex cubic structure exist at high temperatures. Its coefficient of thermal expansion is 8.2×10^{-6} at 20° C., and its resistivity, 2.6×10^{-6} ohm cm. at 0° C.

Though pyrophoric in the finely divided condition, chromium in the massive form is not affected by moist air and only very slowly by dilute acids. Neither fuming nitric acid nor aqua regia attacks it, but with hot concentrated sulphuric acid it gives sulphur dioxide and a dark solution. Warm dilute hydrochloric or sulphuric acid slowly dissolves the metal, hydrogen being evolved with the formation of chromous salts. Heated in hydrogen chloride, the metal yields crystalline colourless chromous chloride, while chlorine yields violet chromic chloride. Chromium is not attacked even by fused alkalies, but fused potassium nitrate or chlorate oxidizes it rapidly to potassium chromate. Heated with sulphur or in hydrogen sulphide, chromium yields chromous sulphide, CrS, whereas with carbon, silicon or boron, various carbides, silicides or borides are formed. Though a chromium carbonyl, $Cr(CO)_6$, is known, it is not formed by heating chromium in carbon monoxide, but by treating chromic chloride with carbon monoxide in the presence of magnesium phenyl bromide. Pyrophoric chromium combines directly with nitrogen to form a magnetic nitride.

Chromium amalgam also combines with nitrogen to form chromic nitride (CrN), chromous nitride (Cr_2N_2) being formed by heating chromium to 850° C. in ammonia.

In addition to the metal, the element exists in the +2 (chromous), +3 (chromic) and +6 (chromate) valence states. The potentials of the oxidation-reduction couples relating the oxidation states are: $Cr=Cr^{++}+2e^-$, +0.86 v.; $Cr^{++}=Cr^{+++}+e$, +0.41 v.; and $2Cr^{+++}+7H_2O=Cr_2O_7^{--}+14H^++6e^-$, −1.36 v.

Chromous Compounds.—As indicated by the potential values, chromous ion may be formed by the reaction $Cr + 2Cr^{+++} = 3Cr^{++}$. The reduction of chromic to chromous also goes readily with zinc. The chromous ion is such a powerful reducing agent that it is readily oxidized to the chromic state even by weak oxidizing agents such as hydrogen ion, $2Cr^{++} + 2H^+ = 2Cr^{+++} + H_2$. The properties of chromous ion are similar to those of ferrous. The colour in aqueous solutions is blue. Chromous fluoride, CrF_2, is green; potassium chromous carbonate, $K_2Cr(CO_3)_2.3H_2O$, is yellow; and chromous acetate, $Cr(CH_3CO_2)_2$, is red. The hydroxide is but slightly soluble and is readily oxidized in air, $4Cr(OH)_2 + O_2 + 2H_2O = 4Cr(OH)_3$. The sulphide and carbonate, like the ferrous salts, are not readily soluble.

Chromic Compounds.—In the properties of its hydroxide and the solubilities of its compounds, chromic ion resembles aluminum ion. However, in its capacity to form double and complex salts, it shows similarity to the cobaltous ion. The hydrous oxide, $Cr_2O_3.nH_2O$, dissolves readily in both acids and strong bases but is readily precipitated by ammonium hydroxide from solutions of its salts. The acidic nature of the oxide gives rise to an extended series of chromites, among these are a number of natural and artificial gemlike minerals called chrome spinels: for example, nickel spinel, $NiO.Cr_2O_3$. The carbonate and sulphide are hydrolyzed to the hydrous oxide. Chromic sulphate forms chrome alums of the type $RCr(SO_4)_2.12H_2O$. The anhydrous chloride, $CrCl_3$, is a beautiful violet colour and dissolves but slowly in water. The aqueous solution of the chloride generally contains the violet ion $[Cr(H_2O)_6]^{+++}$ when the solution is dilute but the ion $[Cr(H_2O)_4Cl_2]^+$ when the chloride concentration is high. Equilibrium is established but slowly between the two ionic species.

Chromic ion forms many complexes, especially with the halides, cyanide, thiocyanates and ammonia. In nearly all these salts it is possible to discern six nonionizing groups attached or co-ordinated to the chromium atom, which is accordingly said to possess the co-ordination number six like cobalt. In the case of the ammonia-addition compounds (*see* AMMINES) whole series are known which are indistinguishable in appearance and general properties from the corresponding cobaltammines. These comprise such types as luteochromic ammines, $Cr(NH_3)_6Cl_3$, purpureo-ammines, $CrCl(NH_3)_5SO_4$, and among many others, praseo-ammines, $CrCl_2(NH_3)_4NO_3$. Complex salts are also formed by replacing ammonia with pyridine, ethylenediamine and similar organic bases. Some of these complex salts have been shown

to be capable of existing in optically active forms, thus proving that the groups co-ordinated to the chromium atom are not planar but have a spatial distribution which is octahedral. The use of chrome alum and chromic fluoride as mordants in fixing soluble dyestuffs on fabrics has been shown to be due to the capacity of the chromium atom to enter into complex formation with the dyestuffs, yielding highly insoluble compounds, often of different colour from the combined dyestuff, firmly fixed on or in the fibre. It is probable that the use of chromium compounds in tanning is due to complex reaction with the organic substances present in hides.

Chromates and Dichromates.—The +6 state of chromium is represented by compounds of the two ions, yellow-coloured chromate, CrO_4^{--}, and orange-red-coloured dichromate, $Cr_2O_7^{--}$. In water solution there exists the equilibrium, $2CrO_4^{--} + 2H^+ = Cr_2O_7^{--} + H_2O$. The value for the equilibrium constant $(C_2O_7^{--})/(CrO_4^{--})^2(H^+)^2$ is 4.2×10^{14}. Thus, in high acid, the ionic species is largely $Cr_2O_7^{--}$ and in alkali CrO_4^{--}. In acid solution, powerful oxidizing agents such as sodium bismuthate are required to oxidize chromic to dichromate, $2Cr^{+++} + 3NaBiO_3 + 4H^+ = Cr_2O_7^{--} + 3Bi^{+++} + 3Na^+ + 2H_2O$. Alkali chromates may be prepared by roasting chromites in air (O_2 oxidizing agent) or by treating chromite with sodium peroxide, $2CrO_2^- + 3HO_2^- = 2CrO_4^{--} + H_2O + OH^-$. Chromic anhydride, CrO_3, or chromium trioxide, may be crystallized from a concentrated solution of an alkali chromate in concentrated sulphuric. It is readily soluble in water, forming chromic and dichromic acids. There are many slightly soluble chromates, but they dissolve in strong acid because of the formation of dichromate ion, $2PbCrO_4 + 2H^+ = 2Pb^{++} + Cr_2O_7^{--} + H_2O$. In very concentrated acid higher polychromate ions exist, and salts of trichromate and tetrachromate may be prepared such as $K_2Cr_3O_{10}$ and $K_2Cr_4O_{13}$. Chromates and dichromates are all therapeutically dangerous, very strongly caustic and destructive of red corpuscles of the blood.

Normal chromates are known of nearly all the stronger bases, both organic and inorganic, and are generally yellow. Ammonium, lithium, sodium, potassium, cuprous, cupric, rubidium, caesium, magnesium, calcium, zinc, cobalt and nickel chromates are soluble in water; strontium and the rare-earth chromates are sparingly soluble in water; mercuric chromate is decomposed by water, while silver, thallous, mercurous, cadmium, barium and lead chromates are insoluble in water. With the exception of cuprous, mercurous and magnesium dichromates which are unknown, all the metals forming soluble chromates also yield soluble red dichromates.

Chromates and polychromates are readily reduced by hydrochloric acid, sulphurous acid, hydrogen sulphide, ferrous salts, alcohol, etc., with formation of chromic salts or hydroxide. The chromates of the strongly basic elements are not readily decomposed by heating, but those of the feebler bases yield chromium sesquioxide and oxygen. Ammonium chromate, on heating or exposure to air, loses ammonia and yields the dichromate, which decomposes with explosive violence on further heating, leaving a residue of chromium sesquioxide, while nitrogen, ammonia, oxides of nitrogen, water and oxygen are also formed.

On treatment of chromates or dichromates with concentrated cold solutions of the halogen acids, or phosphorus halides, salts are obtained, derived from hypothetical half-acid halides; for example, hydrochloric acid and potassium dichromate yield potassium chlorochromate, a salt of the unknown chlorochromic acid $HCrO_3Cl$ or $CrO_2Cl.OH$, the half-acid chloride of chromic acid $CrO_2(OH)_2$. Fluorochromates, chlorochromates, bromochromates and iodochromates of some of the strong bases are known. If chromates or dichromates are treated with a large excess of hydrofluoric or hydrochloric acid, chromyl fluoride, CrO_2F_2, and chromyl chloride, CrO_2Cl_2, are formed. These compounds, which are red volatile liquids yielding red vapours, are the acid fluoride and acid chloride of chromic acid. The bromine and iodine analogues are unknown.

Though chromates and dichromates are readily decomposed by warm solutions of hydrogen peroxide to form oxygen and chromic salts or chromic hydroxide, cold solutions yield little or no oxygen and form peroxidized compounds, nearly all of which yield hydrogen peroxide by suitable treatment and all readily evolve oxygen. It is accordingly inferred that all contain sexivalent chromium as in chromates and dichromates, the extra equivalents of oxygen being in the same form as in hydrogen peroxide. The highest stage of peroxidation is found in the red perchromates of the general formula R_3CrO_8. These salts are obtained by the action of 30% hydrogen-peroxide solutions on alkaline solutions of the chromates at low temperatures. They are unstable at ordinary temperatures and occasionally evolve oxygen explosively. The acid corresponding to these salts has not been isolated. When 97% hydrogen peroxide is added at −30° C. to chromium trioxide, a dark-blue crystalline acid is formed, having the empirical formula H_7CrO_{10} or $H_3CrO_8.2H_2O$. An intense blue coloration is formed on adding hydrogen peroxide to an acidified solution of a chromate, the reaction being sufficiently delicate to detect traces of either reagent. The blue colour is extracted by ether, and the ethereal solution on neutralization by alkalies yields dark-blue salts. These salts have the general formula RH_2CrO_7 and are as unstable as the more oxygenated red salts. If the red or blue salts are treated with excess of an organic base such as pyridine, blue or violet salts are obtained having the general formula $RCrO_5$. If the red perchromates are heated with ammonia to about 40° C., or with potassium-cyanide solution, derivatives of a chromium peroxide of the formula CrO_4 or Cr_2O_8 are obtained. This peroxide may be regarded as an acid anhydride, formed by the loss of a molecule of hydrogen peroxide from two molecules of the acid $HCrO_5$, or one molecule of the dimeric acid $H_2Cr_2O_{10}$. The derivatives of this peroxide yield oxygen and chromates with alkalies, and oxygen, hydrogen peroxide and chromic salts with acids.

Analytical.—Chromium can be detected in compounds by the formation of a green borax bead, by the yellow colour of chromates formed on fusion with potassium nitrate, by the formation of red chromyl chloride and by the blue colour of peroxychromic acid. In the general systematic separation, chromium is precipitated with aluminum since they are not precipitated by H_2S in 0.3*n* H^+, but do precipitate with NH_4OH as the hydrous oxides. When this precipitate is treated with sodium peroxide, the chromium is oxidized to chromate and may be identified by the precipitation of lead chromate from a dilute acid solution after first destroying the excess peroxide by heating. Chromates may be quantitatively determined by reduction with ferrous, $Cr_2O_7^{--} + 6Fe^{++} + 14H^+ = 2Cr^{+++} + 6Fe^{+++} + 7H_2O$, or by reduction with excess of iodide and the titration of liberated iodine with thiosulphate.

CHROMOLITHOGRAPH: *see* LITHOGRAPHY; COLOUR PRINTING.

CHROMOSOME. So called because of their affinity for certain dyes, the chromosomes are minute bodies seen in the dividing cells of which the bodies of animals and plants are composed. Their characteristic configurations and remarkable behaviour in cell division, in the process of development and in the union and formation of the reproductive elements have been the subject of a large body of research, since their discovery in 1873 by Anton Schneider, Flemming, Otto Bütschli and others. The progress achieved during the three decades that followed their discovery made it possible, when J. G. Mendel's law of segregation was rediscovered in the opening years of the 20th century, to identify the structural mechanism predicted by him. From that time on intensive study of the behaviour of the chromosomes in relation to breeding experiments resulted in the building up of one of the most spectacular generalizations of modern biology. An exposition of this chromosome hypothesis is given in the article CYTOLOGY. The word was first used by Wilhelm von Waldeyer-Hartz (1888). (*See* also HEREDITY; GENE.) (L. T. H.)

CHROMOSPHERE is the name which was given by Sir J. Norman Lockyer in 1868 (at the suggestion of William Sharpey, then secretary of the Royal society) to the layer of the sun's atmosphere, just outside the photosphere, which is observed visually when the sun is totally eclipsed and is spectroscopically observable at other times. Observations of the chromosphere had in fact been made before 1868. Thus, C. A. Young (*The Sun*, 1882) mentions that Captain Stannyan, in a report on the eclipse of 1706 observed by him at Berne, Switz., noticed "a blood-red streak of light visible for six or seven seconds upon the western limb," just before the emergence of the sun. It was observed also by Edmund Halley in 1715, and by François Arago, Sir George Airy, Angelo Secchi and others at eclipses in the 19th century. Attention was, however, directed mostly at that time to solar prominences, and the chromosphere escaped serious study. In 1868 Pierre Janssen and Lockyer independently discovered that solar prominences, hitherto only observed at total eclipses, could be seen in full daylight by means of the spectroscope—the principle being that the white light from the sky surrounding the sun's disk was weakened by dispersion on passing through the spectroscope, while any monochromatic constituent of the light from the prominences passed through undispersed and gave rise to a bright line. Lockyer shortly afterward (Nov. 5, 1868) noticed that the prominences jutted out from a continuous spherical envelope surrounding the sun. This envelope was at all times visible in the red (C or $H\alpha$) and blue (F or $H\beta$) lines of hydrogen and in the yellow (D_3) line of the then unidentified element helium. It was to this continuous envelope that Lockyer gave the name chromosphere, in reference to the colour effects seen in the spectroscope.

At a time of total solar eclipse, at the moment of second contact, the chromosphere becomes visible as a thin red crescent, about 10 sec. in thickness, on the east side of the disk. The advancing moon rapidly covers up the layer, which reappears at the western limb just before third contact. The red colour is due to the visual dominance of the $H\alpha$ line of hydrogen.

Astronomers soon recognized that in the chromosphere they must be viewing tangentially the upper layers of the same gases which, when projected against the bright disk, produce the ordinary Fraunhofer absorption spectrum of sunlight, and it was natural to look for confirmation of this. The complete spectrum of the light from the chromosphere might be expected to correspond with the Fraunhofer spectrum, a bright line in the chromospheric spectrum corresponding to each dark line in the Fraunhofer spectrum. This was first verified by Young at the total eclipse of Dec. 22, 1870. Placing the slit of his spectroscope tangential to the advancing limb of the moon, he saw the Fraunhofer spectrum suddenly replaced by a spectrum of bright lines which lasted only two or three seconds. This spectrum was hence called by Young the "flash spectrum." In Young's own words, "as the moon advances, making narrower and narrower the remaining sickle of the sun's disk, the dark lines of the spectrum remain sensibly unchanged though becoming somewhat less intense. A few, however, begin to fade out, and some even turn partially bright a minute or two before totality begins. But the moment the sun is hidden, through the whole length of the spectrum, in the red, the green, the violet, the bright lines flash out by hundreds and thousands, almost startlingly; as suddenly as stars from a bursting rocket, and as evanescent, for the whole thing is over in two or three seconds."

Photography was first successfully applied to the photography of the flash spectrum by A. Fowler and W. Shackleton at the eclipse of April 16, 1893. The flash spectrum may be observed by the use of a tangential slit, as in Young's original observation. But the crescent of atmosphere left exposed by the moon's disk during the period of the flash is so thin that it behaves as a crescent-shaped slit. A direct photograph of the flash spectrum with a prismatic camera without slit reveals a series of crescents, one corresponding to each bright line in the flash spectrum. Each gives an image of the chromosphere and prominences in the corresponding radiation. The thicker the atmosphere as viewed in the light of a particular radiation, the longer will be the arc in the photograph, and it is a matter of simple geometry to deduce the height of the chromosphere in any given radiation from a measurement of the distance from cusp to cusp, using the known diameters of the sun and moon. The following table shows chromospheric heights derived in this way by Lockyer (eclipse of 1898), S. A. Mitchell (1905), C. R. Davidson and F. J. M. Stratton (1926) and D. H. Menzel (1931).

Heights of Elements in Chromosphere from Lengths of Arcs

Element	Radiation	Lockyer 1898	Mitchell 1905	Davidson and Stratton 1926	Menzel 1931

Number of Atoms at a Height H in Kilometres

Menzel, all atoms:

From multiplet intensities.....$\exp\left(-\frac{H}{4050}\right)+59\exp\left(-\frac{H}{1560}\right)$

From microphotometer intensities.....$\exp\left(-\frac{H}{3580}\right)+56\exp\left(-\frac{H}{1050}\right)$

Mitchell and Williams:

Singly ionized titanium.....$\exp\left(-\frac{H}{5000}\right)+60\exp\left(-\frac{H}{2050}\right)$

Iron (of excitation potential 1 v.).....$\exp\left(-\frac{H}{3333}\right)+50\exp\left(-\frac{H}{1067}\right)$

Pannekoek and Minnaert:

Hydrogen.....$\exp\left(-\frac{H}{617}\right)$

Apart from the heights to which the various elements are detected in the chromosphere, the question of greatest interest concerns the distribution of density in the chromosphere. The table also shows the results of various investigations by Menzel, Mitchell and Emma T. R. Williams, and Antonie Pannekoek and Marcel G. J. Minnaert.

As regards wave length, the flash spectrum is an almost exact copy of the Fraunhofer spectrum. The Balmer series of hydrogen extends, however, much further (Stratton and Davidson at Sumatra, in 1926, observed 36 members of the series); also helium is prominent in the flash, while it appears only fitfully and faintly in the Fraunhofer spectrum. But the intensities of the lines in the flash are markedly different from the intensities in the Fraunhofer spectrum. Lines faint in the Fraunhofer spectrum give rise to short intense arcs in the flash; this is easily explained since the faint lines in the Fraunhofer spectrum are probably produced by low-lying vapours at a high temperature, which accordingly shine brightly when viewed tangentially. But in addition many lines are enormously increased in intensity in the flash. It was pointed out by Lockyer that such lines are almost invariably "enhanced" lines; *i.e.*, lines which are relatively strengthened from arc spectra to spark spectra. For example the D-lines of sodium (arc lines) are relatively inconspicuous in the flash; the blue line λ4227 of calcium is much less intense and extends to a smaller height than the H and K lines; the enhanced lines of iron, scandium, titanium and chromium are all strengthened in the flash, and usually extend to greater heights than the unenhanced lines. The flash spectrum, in fact, resembles in many ways the spectrum of stars much hotter than the sun. This was for many years a difficulty, for it was hard to believe that the high-level chromosphere could be hotter than the low-level reversing layer.

The explanation was given by Megnad Saha in 1920. Enhanced lines are now known to be due to the ionized atom (*i.e.*, the atom which has lost one or more electrons) and Saha showed that ion-

ization was promoted not only, as in Lockyer's experiments, by high temperature but also by low pressure. At high temperatures the process of the dissociation of an atom into an electron and a positive ion goes on of its own accord, according to the reversible equation

$$A \rightleftarrows A^{+} + e^{-}$$

until a balance is obtained between the rate of dissociation and the rate of recombination. Reduction of pressure reduces the rate of recombination, while leaving the rate of ionization unchanged, and so favours an increased degree of ionization. Saha showed that at a given temperature and pressure the degree of ionization was calculable, given the ionization potential of the atom. The following table gives the percentage ionization of calcium at 5,000° C. at the pressures mentioned.

Pressure (atmospheres)	10^{-1}	10^{-2}	10^{-3}	10^{-4}	10^{-5}	10^{-6}
Percentage ionization	6.5	20.2	54.5	90	99	(100)

The pressure at the base of the chromosphere is probably less than 10^{-6} atm., and so in the high-level chromosphere calcium must be almost completely ionized. The spectrum must, therefore, be that of the ionized atom, not the neutral atom; hence, the predominance of enhanced lines in the chromospheric spectrum. Similar calculations apply to other elements. The D-lines of sodium, for example, which are due to the neutral atom, are not found in the upper chromosphere, because any sodium there would be completely ionized; the lines of the ionized atom are too far in the ultra-violet to be observable.

The question remains why the chromosphere should extend to such great heights in certain elements. Gravity at the solar surface is about 27 times as powerful as at the earth's surface, and it is readily calculated that under gravity only the solar atmosphere would have a thickness which would be measured in tens of kilometres instead of thousands. (E. A. Mi.)

An explanation with specific reference to the ionized calcium chromosphere was given by E. A. Milne in a series of papers published during the years 1924–27. This theory of Milne is based on the following considerations: when an atom absorbs a quantum of light, and thereby undergoes a transition from one stationary state to another, it experiences a blow in the direction in which the light was moving. In the case of the sun this blow will be in the outward direction. After a short interval the atom must re-emit the quantum, suffering thereby a blow from the recoil, but the recoil blows will be random in direction and will neutralize one another on the average. The net result is that in a succession of absorptions and emissions the atom experiences a series of outward blows. An atom of ionized calcium in the high-level chromosphere experiences about 20,000 such blows per second and this is just sufficient to keep it suspended against gravity. In other words, the pressure of radiation is able to support the ionized calcium atom against gravity and this would account for the enormous extension of the calcium chromosphere. This theory of Milne, attractive in many ways, encounters certain difficulties. For one thing, the density distribution which it predicts does not seem to be in accord with the observations. For another, it appears too special in the sense that it is unable to account for the extent of the other atoms in the chromosphere. This latter failure of Milne's theory, particularly in the case of hydrogen, throws serious doubts on the adequacy of the whole picture; for hydrogen is the most abundant constituent of the chromosphere. These remarks apply not only to Milne's theory but also to other variants of it, as given, for example, by S. Chandrasekhar.

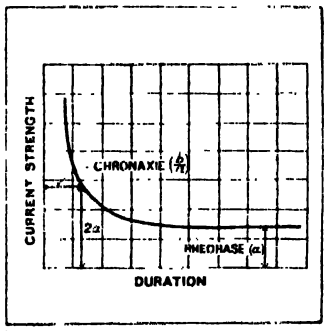
In view of the difficulties encountered by theories based on support from radiation pressure, W. H. McCrea has advanced an alternative theory based on the notion of turbulence. McCrea supposes that the chromospheric gases can be divided into volume elements of finite extent V such that the atomic motion in each group is temperature motion (the temperature corresponding to the ionization and excitation exhibited by the chromosphere) but the elements V themselves have a Maxwellian distribution in velocity corresponding to a temperature $\mathbf{T}$ characterized by a mean velocity C. In the case of an atmosphere consisting of nothing but neutral hydrogen we can expect a relation of the form

$$k\,\mathbf{T} = k\,T + \tfrac{1}{3} M C^2,$$

where M is the mass of the hydrogen atom and k is the so-called Boltzmann constant. The pressure p will be given by

$$p = n\,k\,\mathbf{T}$$

where n is the number of hydrogen atoms per cubic centimetre. Under these circumstances it is not difficult to visualize that the density distribution in the chromosphere will imitate an isothermal atmosphere at the fictitious temperature $\mathbf{T}$. The density distributions in the chromosphere as indicated by the observations would lead to a temperature $\mathbf{T}$ of the order of 18,000° corresponding to a velocity C of about 18 km./sec. It would not seem impossible that turbulent motions of this magnitude exist in the chromosphere. Indeed, there are observations which would lead one to suspect velocities of exactly this order.



Finally, we may refer to an outstanding problem of the chromosphere. The high-level chromosphere rotates around the sun's axis faster than the reversing layer, and moreover does not have the retardation experienced by the latter. No satisfactory explanation had been suggested up to mid-20th century. (Su. C.)

Bibliography.– General accounts of the chromosphere are contained in the following standard works: E. Pringsheim, *Physik der Sonne* (1910); C. G. Abbot, *The Sun* (1911); H. Dingle, *Modern Astrophysics* (1924); S. A. Mitchell, *Eclipses of the Sun* (1923); F. J. M. Stratton, *Astronomical Physics* (1926). *See* also A. S. Eddington, *Stars and Atoms* (1927) and F. J. M. Stratton, *Modern Eclipse Problems* (Halley Lecture, 1927). J. N. Lockyer's early researches on the chromosphere are contained in *Contributions to Solar Physics* (1874) and *Chemistry of the Sun* (1887). Original records of eclipse observations on the chromosphere are given in the following fundamental memoirs: *Phil. Trans. Roy. Soc.*, vol. 187A (1896, J. N. Lockyer, A. Fowler and W. Shackleton); *Mem. Roy. Astron. Soc.*, vol. 54 (appendices) (1901 and 1902, J. N. Lockyer; 1901 and 1903); J. Evershed, vol. 57 (appendix) (1906, F. W. Dyson); *Astrophys. Journ.*, vol. 38 (1913, S. A. Mitchell); *Mem. Roy. Astron. Soc.*, vol. 64 (1927, C. R. Davidson and F. J. M. Stratton). For the rotation of the chromosphere *see* W. S. Adams, *Astrophys. Journ.*, vol. 29 (1909). Saha's fundamental paper on ionization in the chromosphere occurs in *Phil. Mag.*, vol. 40 (1920). The mathematical theory of the equilibrium of the chromosphere is given in E. A. Milne's papers in *Monthly Notices R.A.S.*, vol. 84–87 (1924–27). See also *Monthly Notices*, vol. 87 (1927, S. R. Pike and P. A. Taylor). For recent views on the height of the chromosphere *see* correspondence in *Observatory*, vol. 48, 49 (1925, 1926, J. Evershed, S. A. Mitchell, E. A. Milne, A. A. Buss and G. Abetti); Sir Frank Dyson and R. van der R. Woolley, *Eclipses of the Sun and Moon* (1937); D. H. Menzel, *Lick Obs. Publ.* 17, part I (1931); S. CHRONAXIE or Chronaxia, a term introduced by Louis Lapicque in 1909 to define the character of the stimulus which is required to excite various types of living tissue, particularly muscle and nerve. The most convenient form of stimulus is an electric current, since this can be made to excite (*i.e.*, to cause the tissue to display its characteristic activity) without doing any damage. It is found that a current must fulfil three conditions if it is to excite: (1) it must flow for more than a certain minimal duration; (2) the final strength must exceed a certain value; and (3) the rate of increase of the current from zero must exceed a definite velocity. The need for a minimal duration is shown by the fact that a current alternating at 1,000,000 cycles a second is powerless to excite any tissue in the body; and the modern surgical technique of diathermy is based on this.

The curve relating minimal duration and minimal strength has the form shown in the figure, and as a first approximation it obeys the formula of Weiss, $i = a + \frac{b}{t}$, where i is the current, t its duration and a and b are constants. Lapicque has shown that curves of the same form are obtained from the most diverse tissues, ranging from the human nerve, where the minimal duration is less than .0001 sec., to the cells of a plant where it may be longer than 1 sec. Thus, the character of the stimulus for a given tissue can be defined at once if we know the constants a and b for that tissue. The constant a (the rheobase) is given by the minimal current strength at long durations. The other constant b is the more important, for it determines the slope of the curve, it can be fixed by measuring the chronaxie, which is equal to

$\frac{b}{a}$ and is the least duration required when the current strength is $2a$. The true form of the curve differs somewhat from that given by Weiss's equation, and it has been used as a basis from which to deduce the mechanism of excitation. In Lapicque's hands the measurement of the chronaxie has also been used to investigate the passage of the state of excitation from one tissue to another (*e.g.*, from nerve to muscle). (E. D. A.)

FORM OF A STIMULATING CURRENT IN LIVING TISSUE

The curve shows the relation between the strength and the duration of the smallest current which will excite a living cell. The chronaxie and the rheobase are the two constants which define the curve

CHRONICLE. The historical works written in the middle ages are variously designated "histories," "annals" or "chronicles" (from Gr. χρόνος, "time"); it is difficult, however, to give an exact definition of each of these terms, since they do not correspond to determinate classes of writings. Perhaps the most reasonable definition is that given by H. F. Delaborde at the École des Chartes that chronicles are accounts of a universal character, while annals relate either to a locality, or to a religious community or even to a whole people, but without attempting to treat of all periods or all peoples. The primitive type, he says, was furnished by Eusebius of Caesarea, who wrote (*c.* 303) a chronicle in Greek, which was soon translated into Latin and frequently recopied throughout the middle ages; it embraced the history of the world since the creation. It is certain, however, that mediaeval authors or scribes were not conscious of any clear distinction between annals and chronicles; indeed, they often apparently employed the terms indiscriminately.

In any case, chronicles and annals (*q.v.*) have points of great similarity. Chronicles are accounts generally of an impersonal character, and often anonymous, composed of passages copied from sources which the chronicler is seldom at pains to indicate, and of personal recollections the veracity of which remains to be determined. Some of them are written with so little intelligence that the work of composition seems a mere piece of drudgery imposed on the clergy and monks by their superiors. To distinguish what is original from what is borrowed, to separate fact from falsehood and to establish the value of each piece of evidence is thus a difficult undertaking, and one which has exercised the sagacity of scholars, especially since the 17th century.

The Christian chronicles were first written in the two learned languages, Greek and Latin. At an early stage we have proof of the use of national languages, the most famous instances being the Anglo-Saxon Chronicle (*q.v.*), the most ancient form of which goes back to the 10th century, and the so-called Chronicle of Nestor, in Palaeo-Slavonic, written in the 11th and 12th centuries. In the 13th and 14th centuries the number of chronicles written in the vulgar tongue continued to increase more rapidly on the continent than in England. From the 15th century, with the revived study of Greek and Roman literature, the traditional form of chronicles, as well as of annals, tended to be replaced by another based on the models of antiquity—that of the historical composition combining skilful arrangement with elegance of style. It was not, however, until the 17th century that the traditional form became practically extinct.

See E. Bernheim, *Lehrbuch der historischen Methode*, 4th ed. (1903); H. Bloch, "Geschichte der deutschen Geschichtsschreibung im Mittelalter" in the *Handbuch* of G. von Below and F. Meinecke (Munich, 1903 *et seq.*); Max Jansen, "Historiographie und Quellen der deutschen Geschichte bis 1500," in Aloïs Meister's *Grundriss* (Leipzig, 1906); and the introduction to A. Molinier's *Les Sources de l'histoire de France* (1904). (C. Bem.)

CHRONICLES, BOOKS OF, two Old Testament books of the Bible. The name is derived from *Chronicon*, first suggested by Jerome as a rendering of the title which they bear in the Hebrew Canon; viz., *Events of the Times*. (1 Chron. xxviii, 24; Esth. x, 2, etc.) The Greek translators divided the long book into two, and adopted the title Παραλειπόμενα, "Things Omitted" (*scil.* in the other historical books).

Authorship and Date.—The book of Chronicles begins with Adam and ends abruptly in the middle of Cyrus' decree of restoration, which reappears complete at the beginning of Ezra. A closer examination of those parts of Ezra and Nehemiah which are not extracted from earlier documents or original memoirs leads to the conclusion that Chronicles-Ezra-Nehemiah was originally one work, displaying throughout the peculiarities of language and thought of a single editor, who, however, cannot be Ezra himself as tradition states. The style of the language, and also the position of the book in the Jewish Canon, stamp the book as one of the latest in the Old Testament. In 1 Chron. xxix, 7, which refers to the time of David, a sum of money is reckoned by darics, which certainly implies that the author wrote after this Persian coin had been long current in Judaea. In 1 Chron. iii, 19 *et seq.*, the descendants of Zerubbabel seem to be reckoned to six generations (the Septuagint reads it so as to give as many as 11 generations), and this agrees with the suggestion that Hattush (v, 22), who belongs to the fourth generation from Zerubbabel, was a contemporary of Ezra (Ezra viii, 2). With this it accords that in Nehemiah five generations of high priests are enumerated from Joshua (xii, 10 *et seq.*), and that the last name is that of Jaddua, who, according to Josephus, was a contemporary of Alexander the Great (333 B.C.). A date some time after 333 B.C. is now accepted by most modern critics. (*See* Ezra and Nehemiah, Books of.)

Scope and Object.—The writer lived a considerable time after Ezra and stood entirely under the influence of the religious institutions of the new theocracy. This standpoint determined the nature of his interest in the early history of his people. The true importance of the history of Israel centred in the fact that this petty nation was the people of Yahweh, the spiritual God. The tragic interest which distinguishes its annals from the forgotten history of Moab or Damascus lies wholly in that contest which vindicated the reality of spiritual things and the supremacy of Yahweh's purpose, in the political ruin of the nation which was the faithless depository of these sacred truths. After the return from the Exile it was impossible to write the history of Israel's fortunes otherwise than in a spirit of religious pragmatism. But within the limits of the religious conception of the plan and purpose of the Hebrew history more than one point of view might be taken up. The book of Kings looks upon the history in the spirit of the prophets—in that spirit which is still echoed by Zech. i, 5 *et seq.*, but which had become extinct before the chronicler wrote. The New Jerusalem of Ezra was organized as a municipality and a church, not as a nation. The centre of religious life was no longer the living prophetic word but the ordinances of the Pentateuch and the liturgical service of the sanctuary. The religious vocation of Israel was no longer national but ecclesiastical or municipal, and the historical continuity of the nation was vividly realized only within the walls of Jerusalem and the courts of the Temple, in the solemn assembly and stately ceremonial of a feast day. These influences naturally operated most strongly on those who were officially attached to the sanctuary. To a Levite, even more than to other Jews, the history of Israel meant above all things the history of Jerusalem, of the Temple and of the Temple ordinances. Now the writer of Chronicles betrays on every page his essentially Levitical habit of mind. It even seems possible from a close attention to his descriptions of sacred ordinances to conclude that his special interests are those of a common Levite rather than a priest, and that of all Levitical functions he is most partial to those of the singers, a member of whose guild he may have been. From the standpoint of the post-Exilic age, the older delineation of the history of Israel, especially in the books of Samuel and Kings, could not but appear to be deficient in some directions, while in other respects its narrative seemed superfluous or open to misunderstanding, as for example by recording, and that without condemnation, things inconsistent with the later post-Exilic law. The history of the ordinances of

worship holds a very small place in the older record. Jerusalem and the Temple have not that central place in the book of Kings which they occupied in the minds of the Jewish community after the Exile. Large sections of the old history are devoted to the religion and politics of the ten tribes, which are altogether unintelligible and uninteresting when measured by a strictly Levitical standard; and, in general, the whole problems and struggles of the prophetic period turn on points which had ceased to be cardinal in the life of the New Jerusalem, which was no longer called to decide between the claims of the word of Yahweh and the exigencies of political affairs and social customs, and which could not comprehend that men absorbed in deeper spiritual contests had no leisure for the niceties of Levitical legislation. Thus, there seemed to be room for a new history, which should confine itself to matters still interesting to the theocracy of Zion, keeping Jerusalem and the Temple in the foreground, and developing the divine pragmatism of the history, not so much with reference to the prophetic word as to the fixed legislation of the Pentateuch, so that the whole narrative might be made to teach that the glory of Israel lies in the observance of the divine law and ritual.

Contents.—For the sake of systematic completeness the book begins with Adam, as is the custom with later oriental writers. The early history is contracted into a series of tribal and priestly genealogies, which were doubtless by no means the least interesting part of the work at a time when every Israelite was concerned to prove the purity of his Hebrew descent (*cf.* Ezra ii, 59, 62). Commencing abruptly (after some Benjamite genealogies) with the death of Saul, the history becomes fuller and runs parallel with the books of Samuel and Kings. The limitations of the compiler's interest in past times appears in the omission, among other particulars, of David's reign in Hebron, of the disorders in his family and the revolt of Absalom, of the circumstances of Solomon's accession and of many details as to the wisdom and splendour of that sovereign, as well as of his fall into idolatry. In the later history the ten tribes are quite neglected ("Yahweh is not with Israel," II Chron. xxv, 7), and political affairs in Judah receive attention, not in proportion to their intrinsic importance, but according as they serve to exemplify God's help to the obedient and His chastisement of the rebellious. That the compiler is always unwilling to speak of the misfortunes of good rulers is not necessarily to be ascribed to a deliberate suppression of truth, but shows that the book was throughout composed not in purely historical interests, but with a view to inculcating practical lessons. The more important additions to the older narrative consist partly of statistical lists (I Chron. xii), partly of full details on points connected with the history of the sanctuary and the great feasts or the archaeology of the Levitical ministry (I Chron. xiii, xv, xvi, xxii–xxix; II Chron. xxix–xxxi, etc.), and partly of narratives of victories and defeats, of sins and punishments, of obedience and its reward, which could be made to point a plain religious lesson in favour of faithful observance of the law (II Chron. xiii, xiv, 9 *et seq.*; xx, xxi, 12 *et seq.*, etc.). The minor variations of Chronicles from the books of Samuel and Kings are analogous in principle to the larger additions and omissions, so that the whole work has a consistent and well-marked character, presenting the history in quite a different perspective from that of the old narrative.

Value.—For a critical study of the book it is necessary to compare carefully Chronicles with the parallel narrative in Samuel-Kings. "A careful comparison of Chronicles with Samuel and Kings is a striking object lesson in ancient historical composition: it is an almost indispensable introduction to the criticism of the Pentateuch and the older historical works" (W. H. Bennett, *Chronicles*, p. 20 *et seq.*). Where Chronicles directly contradicts the earlier books there are few cases in which an impartial historical judgment will decide in favour of the later account, and in any point that touches difference of usage between its time and that of the old monarchy it is of no authority. A certain freedom of literary form was always allowed to ancient historians; and the typical speeches in Chronicles are of little value for the periods to which they relate, especially where they are inconsistent with the evidence from earlier writings. According to the ordinary laws of research, the book, being written at a time long posterior to the events it records, can have only secondary importance, although here and there valuable material has been preserved. It must be remembered that the earlier books contain only a portion of the material to which the compilers had access. Hence, it may well happen that the additional details, which unfortunately cannot be checked, were ultimately derived from sources as reputable as those in the books of Samuel, Kings, etc. As examples may be cited Rehoboam's buildings, etc. (II Chron. xi, 5–12, 18 *et seq.*); Jeroboam's attack upon Abijah (II Chron. xiii, *cf.* I Kings xv, 7); the invasion of Zerah in Asa's reign (II Chron. xiv; *see* ASA); Jehoshaphat's wars and judicial measures (II Chron. xvii, xx; *see* I Kings xxii, 45); Jehoram's family (II Chron. xxi, 2–4); relations between Jehoiada and Joash (II Chron. xxiv, 3, 15 *et seq.*); conflicts between Ephraim and Judah (II Chron. xxv, 6–13); wars of Uzziah and Jotham (II Chron. xxvi, *et seq.*); events in the reign of Ahaz (II Chron. xxviii, 8–15, 18 *et seq.*); reforms of Hezekiah (II Chron. xxix *et seq.*, *cf.* Jer. xxvi, 19); Manasseh's captivity, repentance and buildings (II Chron. xxxiii, 10–20; *see* II Kings xxi and MANASSEH); the death of Josiah (II Chron. xxxv, 20–25). In addition to this, reference may be made to such tantalizing statements as those in I Chron. ii, 23 (R.V.); iv, 39–41; v, 10, 18–22; vii, 21 *et seq.*; viii, 13; xii, 15—examples of the kind of tradition, national and private, upon which writers could draw. Although in their present form the additional narratives are in the chronicler's style, it is not necessary to deny an older traditional element which may have been preserved in sources now lost to us.

BIBLIOGRAPHY.—Robertson Smith's famous article in the 9th edition of the *Encyclopædia Britannica* was modified by his later views in *Old Testament in the Jewish Church*, pp. 140–148. Later literature is summarized by Driver in his revision of Smith's article in *Ency. Bib.* and in his *Literature of the Old Testament*, by F. Brown in Hasting's *Dict. Bib.* and by Elmslie (in the Cambridge Bible).

CHRONOGRAPHS. A chronograph is an instrument for making a graphical record by means of which a sequence of events may be accurately co-ordinated with the passage of time. The name is also frequently applied to instruments which give visual indication of the time between two events without making a permanent graphical record. Such instruments are more properly called chronoscopes. A third use of the term is to designate the complete instrumentation used in measuring the velocity of a projectile or other moving object.

VELOCITY CHRONOGRAPHS

The velocity, V, of an object can be determined as the quotient of the increment of its path ds by the time increment dt required to traverse ds. The velocity chronograph consists of two screens, or signalling devices, placed at either end of the path increment, ds, and of the chronograph proper, which records the elapsed time, dt, between the two signals. In the design of the velocity chronograph the first consideration is the accuracy required. For example, in the analysis of the dispersion of projectiles fired from modern cannon with a velocity of about 3,000 ft. per second it is often desired to measure the velocity with an error in the order of 1 ft. per second, or .03%. If the distance between screens is 100 ft. it must be known within $\frac{1}{3}$ in. and the time of flight between screens, which is about $\frac{1}{30}$ sec., must be known within $\frac{1}{100,000}$ sec. As regards knowing the distance between screens the problem is not so much one of measuring the distance accurately, since ordinary surveying methods are sufficient, as it is in designing a screen which gives a signal when the projectile is at a definite position with respect to the screen. Specially designed devices are also required in the measurement of the time.

At least eight different types of screens have been used in the measurement of projectile velocities, the selection depending upon the conditions of the tests and the accuracy required. Perhaps the oldest and most widely used screen, the *Le Boulengé screen* named after Capt. Paul Émil le Boulengé, of the Belgian artillery, who invented it as a component of the Le Boulengé

chronograph, consists of a frame on which a fine wire is strung in many loops to form a fine network. A signal is produced when an electric current passing through the wire is interrupted as the projectile pierces the network. Since electrical contact may be made through the projectile itself, this type of screen is subject to excessive errors. The mass of the wire itself may also appreciably change the velocity of the projectile. An improved screen of the same type has recently been designed in which the electrical current is conducted through a grid printed with conducting ink on a thin sheet of paper.

The *Aberdeen screen* first used extensively at the Aberdeen Proving Ground of the U.S. army ordnance department consists of two conducting foils separated by an insulating sheet. A signal is generated when contact is made between the two foils by the nose of the projectile. This screen has the advantage that it can be used many times. However, it may appreciably alter the velocity of the projectile, and there is intrinsic uncertainty in the time at which contact is first established.

The *solenoid screen,* widely used in many proving grounds, avoids the two main objections to the Le Boulengé and Aberdeen screens. It derives its signal from the voltage generated by magnetic induction when the magnetized projectile passes through a large circular coil of wire. The current induced in the circuit containing the solenoid coil flows first positively as the magnetic flux through it increases; when the magnetic centre of the projectile reaches the centre plane of the coil the current reverses quickly and flows in the negative direction; finally, as the projectile recedes from the coil, the current falls gradually to zero. The sharp crossover from positive to negative current is generally used as the signal for marking the time of passage of the projectile. Although the exact point in the projectile whose passage through the coil produces this signal is never known, it may be assumed that the same point produces the signal in two successive coils. However, there may be some error caused by differences in yaw of the projectile as it passes through the two coils, or by differences in the centring alignment of the coils with respect to the trajectory. *Electrostatic induction* has also been used to produce signals. In this case the screen consists of an insulated loop of wire which forms an antenna through which the projectile passes after it has acquired a static charge of electricity. The potential of the antenna gradually rises as the projectile approaches; it reaches a maximum when the projectile is centred in the loop and then it falls again gradually to zero as the projectile recedes. By means of a suitable amplifier the point of maximum potential can be converted into a pulse of short duration which serves as the desired signal.

Photoelectric screens have been used in two forms. In the telephoto screen an image of the silhouette of the projectile against the light background of the sky is projected by means of a lens onto an opaque disk containing a transparent slit at its centre. As the image passes over the slit, a photocell located behind the disk receives less illumination and there is a change in current through the cell. The sudden increase in illumination when the square base of the projectile image leaves the slit is converted in the amplifier into a sharp pulse which serves as the signal. This type of screen can be used with 90 mm., or larger, shell at distances of 200 ft. from the trajectory, and it thus forms a useful component of a field chronograph. It has the advantage of convenience in setting up, especially for firing tests at high angles of elevation. In another form of photoelectric screen the projectile is fired between a linear light source and a parallel slit behind which is mounted a photocell. The light cut off from the photocell by the shadow of the projectile causes a change in current which is used to generate a signal in much the same way as in the telephoto screen. This type of screen is used extensively in closed ranges for measuring velocities and drag coefficients of small arms projectiles.

Acoustic screens operating from the impact of the bow shock-wave of the projectile upon a microphone have also been used, but variations in the distance between microphone and trajectory introduce errors. The change in the angle of the bow wave with velocity of the projectile is another source of error if the projectile experiences an appreciable change in velocity between the two screens.

For the most accurate measurements of velocity the method of *spark photography* has distinct advantages. In one form the projectile is fired between a photographic plate and a spark gap. An acoustic pickup or one of the other forms of screens already described may be used to trigger the spark while the projectile is in front of the plate. The electric pulse generated by the spark constitutes a signal of less than one microsecond duration and the exact position of the projectile at the instant the spark is fired can be inferred from measurements made on the shadow of the projectile recorded on the plate. In another form used by the German army during World War II a photograph of the projectile is made with two stereoscopic cameras of conventional design using the light of an electric spark for illuminating the projectile against a dark background. After developing the plates, the exact position of the projectile at the instant the spark was fired was reconstructed by reprojecting the images, using the cameras themselves as projectors. Again the spark served as a signal for the time measurements.

Time Measurements.—Up to the end of World War I most ordnance testing establishments measured the time of flight of projectiles between two screens by means of the *Le Boulengé chronograph.* In this instrument the distance of free fall under the acceleration of gravity is used as the basis of the time measurements. The signal from the first screen breaks the current in an electromagnet allowing a weight, in the form of a long rod, to fall freely. The time corresponding to a distance of fall of s cm. is given in seconds by the well-known equation

$$t=\left(\frac{2s}{g}\right)^{\frac{1}{2}}$$

where g is the acceleration of gravity in c.g.s. units and has a value ranging from 978.039 to 983.217 at sea level depending upon the location. The signal from the second screen releases a second weight which falls against a trigger allowing a knife to fly out and mark the falling rod. If both weights are released simultaneously, the knife makes a mark at a distance s_0 corresponding to the dead time,

$$t_0=\left(\frac{2s_0}{g}\right)^{\frac{1}{2}}.$$

The actual time of flight is given by the difference $t-t_0$. Under the conditions of measurement an error of .001 in. in the measurement of the distances s and s_0 corresponds to an error of $\frac{1}{20{,}000}$ sec. in time of flight. The actual errors are somewhat more than this and partly for this reason the instrument has been largely superseded by other more accurate methods.

The *Aberdeen chronograph* was developed during World War I for the U.S. army as a convenient and more accurate instrument than the Le Boulengé chronograph. It consists of a hollow cylindrical drum rotated by a synchronous motor operating from alternating current with an accurately controlled, or accurately measured, frequency of 60 cycles per second. A strip of waxed paper is held by centrifugal force against the inside surface of the drum and it is marked by sparks, triggered by the signals from the screens, which jump through the paper between sharp metallic needle points, mounted close to the inner surface of the paper, and the drum. The paper speed is exactly 1,500 cm. per second and an error of $\frac{1}{4}$ mm. in the measurement of the distance between two spark marks corresponds to an error of $\frac{1}{60{,}000}$ sec. An instrument of similar design with a more slowly rotating drum is used for measuring the time between the firing of a gun and the bursting of the explosive shell.

The *drum camera chronograph* is used extensively for measuring velocities of machine-gun bullets fired in a burst of many rounds, and as a general utility chronograph. In this instrument a strip of photosensitive paper is attached to the outer surface of a drum which rotates inside of a light-tight box, and at the same time moves slowly along its axis to prevent overlapping of

traces made on successive turns. A light beam reflected from the mirror of an oscillographic galvanometer enters the box through a slit and makes a trace on the paper; deflections produced by signals from the screens are thus recorded. On the same record another galvanometer, driven by a standard 1,000-cycle frequency generator, produces time marks at one millisecond intervals. The timing galvanometer is usually arranged to vibrate in the direction of motion of the photosensitive paper and with an amplitude such that the forward velocity of the beam of light at the centre of its swing, where it crosses the slit, is the same as that of the paper. Thus, during that phase of the motion, a sharp, intensely exposed line is produced on the paper, while in the opposite phase of the motion the light is not in contact with the paper long enough for production of a photographic image. In a more refined version of the drum camera chronograph the image of the luminous spot of a cathode-ray tube is focused onto the paper. The signals from the screens are applied to the transverse deflecting plates of the cathode-ray tube and time marks are made by deflecting the beam at one

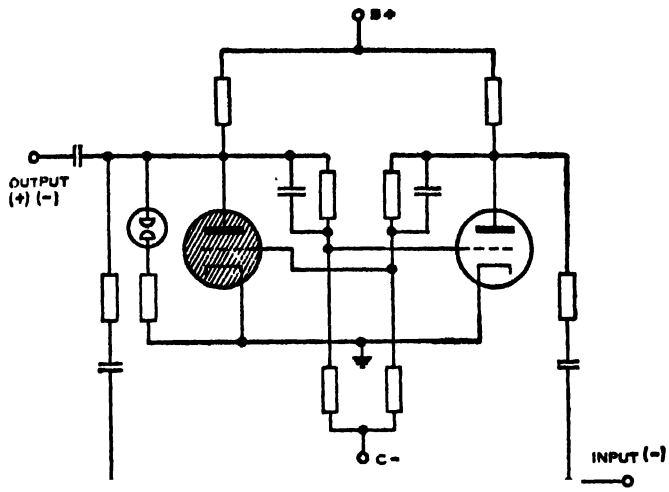

DIAGRAM OF ONE ELEMENT OF THE ELECTRONIC COUNTER CHRONOGRAPH

This circuit is stable with either of the tubes in the conducting state (indicated by the shading) while the other is nonconducting. Each negative pulse applied to the input terminal causes a reversal in the state of the circuit; positive pulses similarly applied have no effect. Negative output pulses are generated when the circuit goes into the state indicated, and these actuate the next stage. Thus, each stage of a circuit, containing several such elements connected in series, sends out half as many negative pulses as are applied to it. The final state of the circuit from which the number, *N*, of pulses applied to it can be determined, is indicated by neon lamps

millisecond intervals to form short pips on the trace. From such a record the time between two signals can be determined with an error of about two microseconds. The *raster chronograph* is a modification of the latter type of drum camera designed to give higher time resolution. In this instrument the cathode-ray beam is swept transversely with sawtooth motion at an accurately controlled frequency of 1,000 cycles per second. The signals are applied to the longitudinal plates, deflecting the beam in the direction of motion of the paper. Thus, the linear distance on the record corresponding to one millisecond is equal to the amplitude of the sweep. The drum speed need be sufficient only to separate one sweep from the next. Another form of raster chronograph capable of a tenfold higher resolution of time than the rotating drum type is one in which the cathode-ray beam scans the screen with several linear horizontal sweeps, each being separated from the preceding one by a small vertical distance to prevent overlap. The signals are applied to the vertical plates, and a photograph of the entire pattern is taken with an ordinary camera. If the lines of the raster are swept with a frequency of 10,000 sawtooth cycles per second and the position of the signals can be determined within 1% of the sweep amplitude, the times can be determined within one microsecond.

During the years just preceding World War II, and during that war, the *electronic counter chronograph* came into use on an ever-increasing scale. This device is based upon an electronic counting circuit first used by Wynn-Williams in England for counting radioactive rays registered by a Geiger counter. It has the great advantage that the time, in units of ten, or even of one, microseconds, can be read directly from the face of the instrument. The complete instrument consists of three parts, a crystal-controlled oscillator, which supplies consecutive pulses at the rate of 100,000 per second (or in the faster instrument at some higher rate), a gate circuit which is opened by the signal from the first screen and is closed by the signal from the second screen, and a counting circuit which registers the number of pulses getting through the gate during the interval while it is open.

In its simplest form the counting circuit consists of a cascaded series of similar circuit elements, each of which may be called a binary pair. One such binary pair consists of two electronic triodes connected together with resistors and capacitors in a so-called trigger circuit which allows one of the triodes to be in a conducting state while the other is held in the nonconducting state. A negative pulse applied to the input point of the circuit reverses the state of the circuit putting the triode which was formerly conducting into the nonconducting state. A small neon tube connecting across one of the triodes glows when that side of the circuit is nonconducting. Finally, a negative pulse is generated by such a binary pair at every second alternation, and this may be used as the input pulse for the next binary pair in cascade. If a series of such circuits is restored to an initial state in which all neon glow tubes are extinguished and then a sequence of pulses is fed into the input point of the first stage the first lamp will glow after one pulse has been received, the second will glow after two pulses, the first and second will glow after three pulses, the third will glow after four pulses and so on. The total count is equal to the sum of a series of terms of the form 2^n where n has the values 0, 1, 2—etc., corresponding to the first, second, third, etc., stages, respectively, and only those terms are to be included in the sum for which the corresponding neon lamps are glowing. By a slight modification of a circuit containing 4 such stages it may be made to recycle to the initial state after 9 pulses have been received, instead of after the 15th as would be the case without the modification. Thus, four binary pairs can be made to form a decade counter and the resulting numbers come out in the decimal system. The conventional electronic counter chronograph for use in measuring the speed of projectiles contains four such decades and it is pulsed at the rate of 100,000 pulses per second. Its range of measurement thus extends from 0.00001 sec. to 0.1 sec. and it gives the time between two signals to the nearest 0.00001 sec. Other counting circuits have operated at more than 1,000,000 pulses per second, and 10,000,000 pulses per second may not be impossible to count in this way.

The development of microwave techniques for radar during World War II afforded the means for designing the *microwave Doppler chronograph* which gave promise of having many practical advantages for measuring the velocities of projectiles under field conditions. In this instrument electromagnetic radiation in the three-centimetre band of wave lengths is projected from behind the gun along a beam which intersects the trajectory and is as nearly parallel to it as the configuration of the gun will allow. Radiant energy reflected backward from the base of the projectile is modified in frequency by the Doppler effect and is received in the same instrument and allowed to beat against the outgoing frequency. Each of the resulting beats corresponds to an increment in the path of the radiation of one wave length of the initial frequency. Half of this distance multiplied by the secant of the angle between the trajectory and the line joining the projectile with the microwave projector is the corresponding distance through which the projectile has moved. In the microwave chronograph an electronic counter records the total number of such units of distance, while another electronic counter records the number of oscillations of a quartz crystal for measurement of the time. The quotient of the former by the latter number is proportional to the velocity of the projectile. (T. H. J.)

ASTRONOMICAL CHRONOGRAPHS

For many years the most common form of time-recording device in astronomical work was the *writing chronograph*, and instruments of this type are still widely used. A writing chronograph utilizes one or more pens, or scribers, writing on paper which moves at a uniform speed beneath them. Sometimes paper tape in roll form is used, while in other cases paper sheets are wrapped around cylindrical drums on which the pens draw spiral lines. The motion of the paper is actuated by weight-driven or electric motors, the speed being usually controlled by centrifugal governors. In the most common form of the single-pen drum chronograph the drum makes either one or two revolutions per minute. The pen is actuated by an electromagnet which is opposed by a spring. When the electric current flowing in the magnet is interrupted, the spring pulls the pen a short distance to the side, producing a jog in the line. A clock or chronometer is connected to produce timing signals, either on every second or on certain seconds of the minute. When such a sheet is removed from the drum, the record for each minute (or half minute) appears as one line across the sheet, and the jogs in the line produced by the timing signals serve as marks for setting a scale. The timing signals should be of short duration so that they will interfere as little as possible with the signals to be measured. In the usual forms of the single-pen chronograph it is possible to make measurements accurately to the hundredth of a second. When two pens are used, one of them serves to record the timing signals and the other the signals which are to be measured, thus eliminating interference between the two sets of signals. Several pens are used when signals from more than one source are to be recorded simultaneously.

Efforts to reduce the labour of the measurements which are necessary with the writing chronograph have led to the development of *printing chronographs*. These devices generally print from rotating type wheels which are driven by governor-controlled motors. In a typical instrument of this kind, manufactured by William Gaertner of Chicago, there are three wheels alongside each other carrying type to print the minute, second and hundredth of a second. The governor is adjusted to run slightly faster than the controlling clock or chronometer. If the type wheels reach the position corresponding to the beginning of a second before a synchronizing signal from the clock is received, the clock wheels are automatically disengaged from the driving motor and held motionless until such a signal is received. In this manner the type wheels are retarded every few seconds by a hundredth of a second, and are thereby kept in fairly close agreement with the clock. The signals, the times of which are to be measured, are connected so that they cause a set of hammers to press the paper against the type wheels. It is necessary that the hammers rebound quickly from the paper, so that the record made by the fastest of the type wheels will not be blurred.

There are of course numerous variations of these instruments. The U.S. naval observatory employs a type of printing chronograph which prints a series of small marks instead of figures, and the time to the nearest five-thousandths of a second is read from the position of these marks. The instrument prints eight columns at once. Its printing wheels are not synchronized with a clock, but the clock signals are printed in one of the columns, thus providing a standard for calibrating the readings in the other columns.

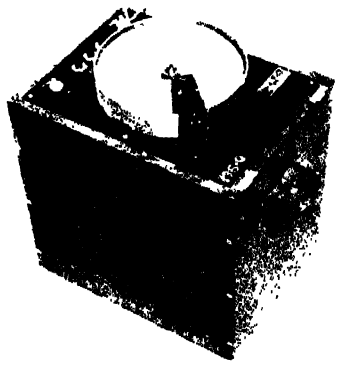
All of the instruments thus far described are limited in their accuracy by the fact that they employ moving mechanical parts. A certain time is required for the motion of these parts, and this time varies according to the strength of the electric current which actuates them, as well as from various other causes. The writing chronograph of one pen is basically the best in this respect, since its travel time is eliminated if it is the same on the clock signals and the signals to be measured. Although such instruments are usually read only to the hundredth of a second, by using a sufficiently fast and uniform drive for the paper they could doubtless be made accurate within two or three thousandths of a second. When more than one pen is used, however, an error of several hundredths of a second can easily arise from the variable lags and uncertain relative positions of the different pens. The chronographs which print figures are also subject to similar errors, mostly because of the variable reaction times of the hammers. The fact that the type wheels are usually slightly out of synchronism with the master clock also contributes to this error.

The elimination of the errors which are caused by the moving mechanical parts has been made possible by the use of electron tubes and their associated equipment. These tubes make it possible for very feeble currents to control powerful ones without the use of mechanical relays, and with negligible time delay. Moreover, they have made possible a new type of time keeper, the quartz crystal-controlled oscillator. In this device the vibrating crystal takes the place of the pendulum. Since the frequency of the crystal oscillations is high, a means is provided of dividing the second into small parts. Alternating current of various frequencies may be generated, making it possible to operate synchronous motors in unison with the crystals.

One form of chronograph which may be conveniently driven by a synchronous motor is the *spark chronograph*. This type of device utilizes electric sparks to perforate or mark the recording paper. Ordinary paper may be used, although the record is rendered more legible by the use of waxed or chemically treated paper.

Alfred Loomis of Tuxedo Park, N.Y., constructed such a chronograph for making continuous comparisons of several precision clocks. Roll paper is utilized, moving slowly under a row of 100 electrodes which extend across the paper's width. Wires lead from the electrodes to a distributor which connects them in rotation to the source of the electric spark. The period of rotation of the distributor is one-tenth of a second, so that each electrode is capable of being energized during an interval of one-thousandth of a second. When a clock producing seconds signals is connected to control the sparks, these sparks occur every ten revolutions of the distributor. As long as the chronograph driving motor runs in exact synchronism with the clock, the sparks will always pass through the same one of the electrodes. As a result a straight line of perforations will be produced on the paper. If the signal clock gains or loses with respect to the chronograph mechanism, however, the line of perforations will move diagonally across the paper. Several clocks may be connected to the recorder at the same time. Each clock then produces a line of perforations on the sheet, and the relative inclinations of these lines indicate the relative rates of the clocks. The differences of the times indicated by the various clocks may be read off at any time, so far as the hundredth and thousandth parts of the second are concerned, but the whole seconds and tenths must be otherwise determined.

Later designs of the spark chronograph have eliminated the wiring between the distributor and the spark electrodes. The national bureau of standards has an instrument in which this is accomplished by causing the paper to pass between a metal cylinder, rotating several times per second, and a metal strip or comb. The length of the cylinder is about equal to the width of the paper. The sparks jump from a ridge on the cylinder to the metal strip. The ridge is spiral in shape and extends just one turn around the cylinder. As the cylinder makes each revolution the point on the spiral which is closest to the paper and the metal strip therefore moves across the width of the paper. The records secured are similar to those described.



The U.S. naval observatory developed a *photographic chronograph* which makes use of a flashing gas-filled lamp, and records figures showing the times of signals in minutes, seconds and thousandths. A 1,000-cycle alternating current, controlled by a crystal oscillator, is used to drive a synchronous motor at 10 r.p.s. A dial attached to the motor shaft is engraved from 00 to 99 to indicate the hundredth and thousandth parts of the second. Other slower moving dials are located alongside to show the tenths of seconds, whole seconds and minutes. All of these dials are in a dark box. When signals are received, they cause the flashing lamp to illuminate the figures. A suitable lens

1. Solenoid screens on a 100-ft. base line for measuring velocities of projectiles fired at low angles. The wooden frames support wire coils in which signals are generated when the magnetized projectile passes through
2. The Aberdeen chronograph, showing the hollow drum which contains the record paper. Spark points which mark the paper when excited by signals from the screens are mounted under the bracket projecting into the drum
3. An electronic counter chronograph with a capacity of 10,000 counts
4. One of a pair of spark photographs used for determining the successive positions of a projectile in the precise measurement of its velocity. The illuminating spark, which is triggered after a brief time delay by a voltage pulse induced by the projectile on the antenna wire at the left, has a duration of about one-tenth microsecond. The position of the projectile is determined with reference to the notches in the mask along the lower edge of the plate. The time between the two sparks used in making a pair of such plates is measured by a megacycle counter chronograph

forms a reduced image on microfilm. The accuracy of the device is such that the ten-thousandth of a second may be estimated from the position of the figures showing the thousandth of a second, with an error of one or two ten-thousandths. (P. Sr.)

CHRONOLOGY, a time scale, a system of reckoning time massively. In testimony of the social memory and of the classification and exploitation of social experiences embedded therein mankind has learnt to recognize the orderly recurrence of natural phenomena and to base thereon his calendar (*q.v.*).

Astronomy.—Every science has now its chronology. The astronomer reminds us that "looked at in the astronomical time-scale, humanity is at the very beginning of its existence—a new born babe, with all the unexplored potentialities of babyhood" (J. H. Jeans in *Nature,* Supplement [March 1928]); so that the chronology of the astronomer "uses a clock which does not tick seconds but years: its minutes are the lives of men." It tells us "that light travelling 186,000 mi. a second, takes about 140,000,000 years to come to us from the most remote objects visible in the biggest telescope on earth" (*ibid.*).

Geology.—We turn now from chronology of this vastness—to the chronology of this habitable globe, to the time scale of geology (*q.v.*) which is based for its larger divisions on the record of physical events, displaying ice ages, periods of mountain building, of tectonic activity. By the aid of palaeontology, smaller divisions are established: yet here again we deal with vast figures.

Anthropology.—The earth (*q.v.*) must be 2,000,000,000 years old and man from the best evidence now available has existed thereon for something like 300,000 years.[1] Where then—with a time measure as our scale—shall we place the beginnings of our race? Each division of an inch stands for 160,000,000 years, so we divide the last of our inches of our scale by 50 and there place the first appearance of man. Where shall we place the Piltdown man (*see* MAN, EVOLUTION OF), or Heidelberg man? Divide one fiftieth of an inch into tenths and mark the fifth of these divisions the age of Piltdown man.

Archaeology.—Where shall we put the beginnings of the Neolithic age, when agriculture, domestication, settled life, metallurgy all have their beginning? It is so near us that we cannot mark it successfully. We can no longer use our big scale. We must change our scale and take a scale of 12 in. to represent the 300,000 years of man's existence. Each inch stands for 25,000 years and we must place the dawn of what is essential to modern life about halfway in the last or 12th of our inches. Ur and its treasures go to 3500 B.C. or 5,000 years ago and are one fifth of an inch from to-day. Egypt is but a century or two later. The Indus civilization comes next and then that of China. The archaic culture of Central America is 3,000 years old, but by then great empires in the east had waxed and waned and disappeared. Egypt was then old Egypt; and the Greeks like Herodotus were children in cultural growth.

History.—Again we must change our scale. If we take the Neolithic age as 12,000 years ago, as a basal point (ignoring thereby all the Palaeolithic and Eolithic periods), each inch stands for 1,500 years. The discovery of the new world called America comes half way in the last inch upon this scale and there is so much to cram into the last tenth of the last inch that we are almost tempted to augment our scale once more.

Dynastic Reckoning.—When we come to the great civilizations of antiquity in the valleys of the Euphrates, the Tigris and the Nile or in China, we find established the method of chronological computation by reckoning dynasties of rulers. Social continuity finds its expression and its measure in this development of social organization. But dynasties are human, and disappear. Within the framework of historical chronology we may at will establish periods based on the varying phases and variable elements of human culture. The founders of great religions are remembered in the chronologies of their followers. There are great periods in art, in literature, in science, not inaptly recorded and recollected and concentrated by the names of great individuals. It is still true that the world forgets. The record of their existence and often their deeds are being revealed to us by archaeology (*q.v.*) so that we seem to know more of them and their forerunners than they even knew themselves. Yet in their flourishing days, which by scale of time are so near to us and by scale of culture seem so different, there was behind them a long past, unheeded, ignored, yet potent in their lives as their achievements are still potent in and even essential to our lives. (*See* CALENDAR.)

[1] Sir A. Keith places the Piltdown skull as of 1,000,000 years ago.

CHINESE

From the time of the emperor Yao, upward of 2,000 years B.C., the Chinese had two different years—a civil year, regulated by the moon, and an astronomical year, which was solar. The civil year consisted in general of 12 months or lunations, but occasionally a 13th was added to preserve its correspondence with the solar year. Even at that early period the solar or astronomical year consisted of 365¼ days, like our Julian year, arranged in the same manner, a day being intercalated every fourth year. The civil day begins at midnight and ends at the midnight following.

Since the accession of the emperors of the Han dynasty, 206 B.C., the civil year of the Chinese has begun with the first day of that moon in the course of which the sun enters into the sign of the zodiac which corresponds with our sign Pisces. From the same period also they have employed, in the adjustment of their solar and lunar years, a period of 19 years, 12 of which are common, containing 12 lunations each, and the remaining 7 intercalary, containing 13 lunations. It is not, however, precisely known how they distributed their months of 30 and 29 days, or, as they termed them, great and small moons.

The Chinese divide the time of a complete revolution of the sun with regard to the solstitial points into 12 equal portions, each corresponding to 30 days, 10 hours, 30 minutes. Each of these periods, which is denominated a *tsieh,* is subdivided into two equal portions called *chung-ki* and *tsie-ki,* the *chung-ki* denoting the first half of the *tsieh,* and the *tsie-ki* the latter half. The *tsieh* are thus strictly portions of solar time, and give their name to the lunar months, each month or lunation having the name of the *chung-ki* or sign at which the sun arrives during that month. As the *tsieh* is longer than a synodic revolution of the moon, the sun cannot arrive twice at a *chung-ki* during the same lunation; and as there are only 12 *tsieh,* the year can contain only 12 months having different names. It must happen sometimes that in the course of a lunation the sun enters into no new sign; in this case the month is intercalary, and is called by the same name as the preceding month, with the addition of the word *jun* (intercalary). (X.)

EGYPTIAN

The chronology of Ancient Egypt has been ascertained by means of the statements of classical authors, by regnal years and other indications on the monuments, by the results of close archaeological study, and the ascertaining of certain fixed astronomical data, checked by comparison with the known chronology of the ancient nations which afford synchronisms with events in Egyptian history. The Egyptians never possessed a regular era, as the Assyrians did with their list of *limmu* officials (*see* BABYLONIA AND ASSYRIA). Only once is an era mentioned, in the description of Rameses II, mentioning the 400th year of the Hyksos king (?) Nubti which fell in his reign. We only hear of such and such a regnal year of a king or, in early days, of the years of certain fiscal numberings. Regular regnal annals are very rarely preserved, though we have fragments of them in the Old Kingdom in the Palermo stone, and there is of course the famous *Turin Papyrus of Kings,* which is invaluable even in its mutilated condition. Under the 12th and 22nd dynasties the custom of the association of fathers and sons on the throne enables us to check the chronology of the overlapping years of those periods (as when the 10th year of one king is stated to be the first of another), and so reconstitute the length of the dynasty with some accuracy. The use of synchronisms with Mesopotamian history is evident when we see that the reign of Rameses II is contemporary with that (of certain date) of Shalmaneser I of Assyria (*c.* 1250 B.C.), a datum with which other synchronisms agree. And dates fixed astronomically are of great importance. The Egyptian did not note eclipses

as the Mesopotamian did, so that we have not this evidence. But we have the observations of the heliacal risings of the star Sothis (Sirius), which have supplied us with certain fixed dates which are of great importance, the more so as they agree with the results obtained from synchronisms. The Egyptian calendar was regulated by the observations of the heliacal risings of Sirius, which were supposed to take place on the first day of the first month of the year. But as an additional leap year day was not intercalated every four years in addition to the year of 360–5 "epagomenal" days, the months gradually lost all relation to the seasons, and it was not till 1,460 years after the last accurate coincidence that the heliacal rising of Sirius again took place accurately on the first day of the first month. When it did the event was celebrated as the beginning of a new "Sothic cycle." We know that a new cycle began either in 139 or in 143 A.D. An Alexandrian mathematician calls the initial year of the preceding cycle (1321 or 1317 B.C.) the "epoch of Menophres." The "throne-name" of Rameses I., who began to reign, it is known from the synchronism of Rameses II. with Shalmaneser III., about 1320 B.C., is Menpehtira or more shortly Menpehra' (a form that constantly occurs), which is obviously "Menophres." Now it would appear from contemporary evidence that Sothis rose heliacally on the first day of the month Pharmouthi in the seventh year of Senusret III., of the 12th Dynasty; so that it would seem easy to calculate that the seventh year of that king should be 1876 or 1872 B.C. (although another computer [Nicklin] has arrived at the date 1924 B.C. for the same year), on the assumption that this king reigned during the immediately preceding cycle which began in 2781 or 2778 B.C. Here, since synchronisms fail us, our knowledge of the historical development of Egyptian civilization and art comes to our aid to assure us that this must have been so, in spite of the fact that it is very difficult to square the lengthy list of kings given us by the Egyptians themselves with so short an interval as the two hundred years only which, if this conclusion is right, can have elapsed between the end of the 12th Dynasty and the beginning of the 18th. If it is right, the 12th Dynasty must have ended about 1788 B.C., and we know that the 18th cannot have begun later than 1580, from our full knowledge of the length of the reigns of that dynasty, confirmed by records of certain new-moon festivals at the time, as well as by synchronisms. So short is this period that Prof. Sir Flinders Petrie has preferred the view that Senusret and the 12th Dynasty really belong to the preceding cycle, and so go back to the fourth millennium B.C. This view however goes clearly against our archaeological knowledge. The resemblances between the culture of the early 18th Dynasty and the 12th are enough to forbid us to suppose that 1600 years elapsed between them, an epoch as long as that which separates Augustus from Queen Elizabeth. And our knowledge of the development of Minoan civilization (*see* AEGEAN CIVILIZATION) confirms this prohibition. The 12th Dynasty was contemporary with the Second Middle Minoan period; the early 18th with the First Late Minoan period. No student of Minoan archaeology could admit that these two Cretan epochs were separated by more than two or three centuries; 16 is impossible. Yet the fact remains that only two centuries or at the most three between the 12th and the 18th Dynasties are rather hard to accept. Four would seem more probable; and so it remains a moot question whether or not something has happened, some mistake in the observation of the star, or some unrecorded modification of the calendar, which would invalidate the modern calculation of the distance of time between Senusret and Rameses I. If, however, it is maintained that no such mistake is possible, then we must accept 1788 as the latest date of the end of the 12th Dynasty, 1861 B.C., as the earliest. The length of the dynasty we know from its recorded reigns to have been 212 years, so that it began about 2000 B.C. or about a century earlier, unless we choose to allow a little more time for a possible error, and suppose a date for it of *c.* 2212–2000 B.C. Further back we reach a state of great uncertainty. There are no synchronisms and no Sothic records to help us. The length of time between the beginning of the 12th Dynasty and the end of the 6th is unknown, but it cannot have been longer than two or three centuries. The Turin papyrus comes to our help with the statement that 955 years elapsed between the beginning of the 1st Dynasty and the end of the 8th, a statement that agrees with historical and archaeological probability, and if we reckon the latter at about 2400 B.C. we reach 3350 as that of "Menes," the conflate founder of the kingdom (=the historical kings "Scorpion," Narmerza, and "Ahai") (*see* EGYPT: *History*; *Art*). But Prof. Meyer now takes *c.* 3200 B.C. as the date of "Menes," assuming, as we have not, that the Sothic date of Senusret III. is incontrovertible. We have assumed 2212 as the beginning of the 12th Dynasty, and 2370 as that of the beginning of the 11th. The 8th may well have been contemporary with the 9th and 10th (Herakleopolites) and have lasted until *c.* 2400. If the "Kahun" date is correct, as Meyer assumes, and the end of the 8th dynasty is brought down to 2300, the Sothic cycle that began in 2781 or 2778 B.C. will then have fallen about the time of the 3rd Dynasty. If 2400 is taken as the date it will have fallen as late as the 5th. In either case, the yet earlier cycle-era in 4241 or 4238 B.C. will belong well before the beginning of the kingdom. And it has been supposed that the calendar must have been invented at that time, because the calendar was known before the 4th Dynasty. But the invention of a calendar presupposes a settled state and civilization, not the undeveloped culture of the predynastic period, though we do not know that there did not exist in Lower Egypt before the unification a political state where culture was sufficiently developed for such an invention to be made, and there have been considered to exist indications of the existence of such a state. Still, eight centuries between the invention and the unification under Menes is a very long time for such a hypothetical civilization to have endured apart from the fact that such an invention as a calendar must have occurred at the end of its development rather than its beginning; and recently a suggestion has been made by Dr. Scharff that revolutionizes our ideas on this point. This is that since the older date is so improbable the invention of the calendar in reality took place in 2781–2778 B.C., and since it was known before the time of the 4th Dynasty, this dynasty must in reality be later than that date, so that this Sothic cycle probably began about the time of the 3rd Dynasty. And it is significant that it is precisely in the time of the 3rd Dynasty, in the reign of king Zoser, that the great development of Egyptian culture took place that is ascribed to the inspiration of that king's minister, Imhotep, who was later deified as the patron of art and learning, including medicine, architecture, astronomy and science generally. It is then surmised that the calendar was invented by Imhotep or in his time, and that therefore the date 2781–2778 falls in the reign of Zoser. Now if this new surmise is correct, the 1st Dynasty will have begun rather later than 3200 B.C., and then the end of the 8th Dynasty will certainly fall about 2300. But in this case we shall have to assume the astronomically calculated "Kahun" date of Senusret III. to be unquestionably correct, as Meyer does, and must accept two centuries only between the 12th Dynasty and the 18th, in spite of the long Turin list of kings of this period, who then must have been mostly very ephemeral rulers. In any case the ancient list-compilers were evidently as much at sea in the two "intermediate" periods (6th–12th and 12th–18th Dynasties), as we are, for they suffered from absence of reliable material just as we do.

In later days, after the time of Rameses II., we have various data to help us. The date of Sheshonk (Shishak), the contemporary of Rehoboam and founder of the 22nd Dynasty, is fixed to *c.* 930 B.C. by Assyrian and biblical evidence, and for the Ethiopian kings, Shabak, Taharka and the rest, we have the fixed synchronisms with Assyrian kings whose dates are fixed by the *limmu*-lists. From the time of Psammetichus I., the founder of the 26th Dynasty, Babylonian and Greek authorities assist us, and his date is definitely known to be 663 (651 independent of Assyria)–609 B.C. After him we are dealing with the known facts of general ancient history as reported by the classical historians.

BABYLONIAN AND ASSYRIAN

Evidence of Babylonian documents, from 330 B.C. onward, dated by kings' regnal years has settled many points in relation to the chronology of late as well as of early periods, though this evidence has been much discussed and often wrongly represented. It is now fairly clear that the era of the Arsacid dynasty was reckoned from 1st Nisan, 246, and that apparent divergences from this reckoning depend on ancient scribal errors or modern errors of interpretation. The Seleucid era was reckoned from 1st Nisan 311. There was no difference between "civil" and "religious" reckoning, as has sometimes been maintained. The reckoning of the Seleucid era from 311 B.C. must have been introduced in or before 305 B.C.; the years before that were actually spent by the Babylonians in a state of confusion as to dating which was introduced with the advent of Alexander the Great. The confusion was due in part to the use of two systems; in one reckoning, the year dates according to the Macedonians was used, in another a dating strictly true of Babylon only, but this will not explain every case. The effect of this may be seen from the following list:—

Year	King	Numbering (*a*)	Numbering (*b*)
330–329	Alexander the Great	7th	1st
323–322	Philip Arrhidaeus	2nd	1st
317–316	Alexander IV	..	1st
316–315	Antigonus	1st	2nd

The exact method of dating between 311 and 305 is not certain; a broken document renders it possible that 311 was called "the seventh year of Alexander and Seleucus," *i.e.*, that Seleucus associated his name with the king's for the first time, and that would account for the Babylonian reckoning of the Seleucid era. It should be noted that from the advent of Alexander the year reckoning commenced immediately from the accession of the king.

From 626 B.C.–331 B.C.—The ordinary Babylonian reckoning of regnal years, always observed before the Macedonian invasion, was from the 1st Nisan after a king's accession; months or days prior to Nisan were reckoned "beginning of kingship." There are two sources for the chronology of the New Babylonian and Persian empires, the canon of the Greek historian Ptolemy, and the reckoning which can be traced almost month by month and day by day; the tablets give names of rebels against the Persian kings otherwise unknown, and allow of more accuracy in dating, *e.g.*, the coregency of Cambyses to the first year only of his father's reign.

New Babylonian Empire	Accession	1st full year
Nabopolassar	626	625
Nebuchadrezzar II	605	604
Evil-Merodach	562	561
Neriglissar	560	559
Labashi-Marduk	556	...
Nabu-na'id	...	555
Persian Empire.		
Cyrus	539	538
Cambyses	...	529
"Smerdis," Nebuchadrezzar III	...	522
Darius I	522	521
Xerxes I	486	485
Artaxerxes I	465	464
Darius II	...	423
Artaxerxes II	...	404
Artaxerxes III (Ochus)	...	358
Arses	...	337
Darius III	...	335

Between 648 and 626 B.C.—The dating of the New Babylonian empire secures the long uncertain dating of the fall of Nineveh; a chronicle, dating by the regnal years of Nabopolassar, places that event in 612 B.C. The period from 648 to 626, the accession year of Nabopolassar, is still very obscure; the statements of Ptolemy's canon cannot exactly accord with the facts. Dating by Sin-sharishkun, the last king of Assyria up to the 7th year has been found at Sippar; since this year must at latest be 616, his first full year must at latest be 622. A certain Sin-shum-lishir, intervened between Assur-etil-ilani, who reigned at least four years, and Sin-sharishkun, so that reckoning by Ashur-etil-ilani commenced in 627 at latest. Between 648 and 626 documents were dated by Kandalanu, the Kineladan of Ptolemy's canon; that this was a name assumed by Assur-bani-pal as king of Babylon is doubtful, as there are good grounds for assuming that cuneiform scribes distinguished between the two. But since a building inscription dating from Assur-bani-pal's 30th year has been found in Babylon, *i.e.*, 639 B.C., the Assyrian must have claimed the kingship also.

From 911–648 B.C.—Assyrian chronology depends on lists of eponymous officials called *limmu*, by whom years were dated. These lists were drawn up in two ways; the first class consists of simple lists of names, the second gives in a column opposite the name an entry concerning the events of the year. An entry opposite the name Pur-Sagale reads, "Governor of Gozan. Revolt in the city of Ashur. In Siwan there was an eclipse of the sun," and this eclipse has been astronomically fixed as having taken place on June 15, 763 B.C. This fixes the years of all *limmus* in the continuous list which reaches from 890–648. There are discrepant versions of these *limmu* lists which affect the reigns of Adad-nirari III and Shalmaneser III; these kings are allowed 29 or 28 and 35 or 34 eponyms to their reign. The weight of authority seems to lie with the lower numbers, but the question is not definitely settled; otherwise the Assyrian chronology of the period is fixed.

The Babylonian chronology of the time is less certain. Ptolemy's canon and cuneiform documents give the regnal years from Nabonassar's first year, 747 B.C. The belief that some kind of era commenced then is baseless; it was chosen by Ptolemy for some accidental reason, perhaps because that was the first fixed point that was known to him, but not for any scientific reason. Before Nabonassar, the continuous king-list is now known to have included between Shamash-mudammiq, who was reigning about 910 B.C., and Nabonassar 16 names, an average of about 10 years apiece, but the exact lengths of reigns cannot yet be ascertained.

Babylonia		*Assyria*	
Shamash-mudammiq, abt.	910	Adad-nirari II	911–889
Nabu-shum-ukin		Tukulti-Enurta II	889–884
Nabu-apal-iddin	?–851	Assur-nasir-pal II	884–859
Marduk-bel-usate	851–850	Shalmaneser III	859–824
Marduk-zakir-shum	850 839

Sennacherib	688–681		
Esar-haddon	680–669	Esar-haddon	680–669
Shamash-shum-ukin	668–648		
Kandalanu	647–626	Assur-bani-pal	668–638 (?)

From About 1380–911 B.C.—There are broken *limmu* lists which once gave the eponymous officials from about 1200 B.C.; in their present state they give a framework for the Assyrian kings

from about 1068–911, the margin of error within which is not more than ten years. Complete king-lists for Assyria being now obtained from broken documents, approximate dates for the kings of the 13th century can be based on intervals sometimes mentioned between them and later kings. The approximate date of Ashur-uballit can be determined from his correspondence with Akhnaton, the Pharaoh of Egypt, with a marginal error of ten years, as about 1380.

Babylonian chronology depends upon the cases where the number of years are known, and on synchronisms with the Assyrian kings. The result can only be an approximation with a margin of error perhaps exceeding a decade. The arrangement is then roughly:—

Babylonia	*Assyria*	
Burnaburiash	Ashur-uballit . .	1380–1335
Karaindash		
Kadashman-kharbe		
Shuzigash		
Kurigalzu III. (23 years)	Enlil-nirari . . .	1335–
	Arik-den-ili . . .	–1311
Nazimaruttash (26 years)	Adad-nirari I. . .	1310–1280
Kadashman-turgu (17 years)	Shalmaneser I. . .	1280–1250
Kadashman-Enlil (6 years)		
Kudur-Enlil (9 years)		
Shagarakti-shuriash (13 years)	Tukulti-Enurta I. .	1250–1216
Kashtiliash (8 years)		
Enlil-nadin-shum (1½ years)		
Kadashman-Kharbe (1½ years)		
Adad shum-iddin (6 years)		
Adad-shum-nasir (30 years)	Ashur-nadin-apal .	1215–1212
	Ashur-nirari III. .	1211–1206
	Enlil-kudur-usur .	1205–1201
Meli-shipak (15 years)	Enurta-apal-ekur .	1200–1188
Merodachbaladan I. (13 years)	Ashur-dan I. . .	1187–1150
Ilbaba-shum-iddin (6 years)		
Enlil-nadin-akhkhe (3 years)		
Marduk-shapik-zeri (17 years)		
Enurta-nadin-shum (6 years)		
Nebuchadrezzar I.	Enurta-tukulti-Ashur	
	Mutakkil-Nusku	
Enlil-nadin-apal	Ashur-resh-ishi I. .	?–1099
Marduk-nadin-akhkhe	Tiglathpileser I. . .	1098–1068
Itti Marduk-balatu	Enurta-apal-ekur II .	1067–
Marduk-shapik-zer-mati	Ashur-bel-kala	
Adad-apal-iddin (22 years)	Eriba-Adad II.	
	Shamshi-Adad IV. .	–1048
Marduk-akhkhe-eriba (1½ years)	Ashurnasirpal I. . .	1047–1027
Marduk-zer (12 years)	Shalmaneser II. . .	1026–1015
Nabu-shum-libur (8 years)	Ashur-nirari V. . .	1014–1009
Simmash-Shipak (18 years)	Ashur-rabi II. . .	1008–?
Ea mukin-zer (5 months)		
Kashshu nadin-akhkhe (3 years)		
Eulmash-shakin-shum (17 years)		
Enurta-kudur-usur (3 years)		
Shiriqtum-Shuqamuna (3 mos.)		
Marbiti-apal-usur (6 years)		
Nabu-mukin-apal (36 years)	Ashur-resh-ishi II. .	?–964
Enurta-kudur-usur	Tiglathpileser II. .	963–933
Marbiti-akh-iddin	Ashur-dan II. . .	932–912

Before 1380 B.C.—All earlier chronology must be subject to considerable margin of error. It depends on (1) Babylonian king-lists which give the number of regnal years; in many instances, where these figures can be checked by other sources, they are proved unreliable; (2) statements of Assyrian kings about their predecessors; the figures given are sometimes round numbers, and are never absolutely reliable; (3) dead reckoning on the basis of generations, coupled with the use of the rare synchronisms known between the two countries.

The Babylonian king-list allows 36 kings, and 576 years 9 months for the period during which the country was ruled by Kassite kings. Enlil-nadin-akhkhe, the last of the dynasty, succeeded to the throne in the time of Ashur-dan I., roughly about 1170, within a decade, and ruled three years: this would place Gandash, the first king, about 1743–42, but an increased margin of error must be allowed owing to the inaccuracy of the list. The 13th Kassite king, Ulam-Buriash, may have ruled about 1530–20; he occupied the Sea-land, the marshes at the head of the Persian gulf, when the last independent king of the Sea-land fled to Elam. This Sea-land dynasty numbered, according to variant accounts, 11 or 12 kings, who ruled for the long period of 368 years, which would place Iluma-ilum, the first king, about 1900 B.C., if the last king fled just before 1530 But Iluma-ilum can be proved by various documents to be a contemporary of Samsu-iluna and Abi-eshu', kings of the 1st dynasty of Babylon. Iluma-ilum is said to have reigned 60 years, and Samsu-iluna and Abi-eshu' reigned respectively 38 and 28; it is not probable that Samsu-iluna began to reign before Iluma-ilum, and if he be assigned a date about 1900–1863, the end of the 1st dynasty is brought to about 1746, almost immediately before the accession of the first Kassite king This cross-reckoning is satisfactory in itself and supported by the Assyrian king-list. There were 42 kings between Ilushuma, an early governor of Ashur, and Ashur-uballit, about 1380. According to kings' statements Ilushuma lived about 2000 B.C., and this accords roughly with other statements about his son. It is certain from an entry in a chronicle that Ilushuma carried out some military enterprise in Babylonia in the time of Sumu-abu, the first king of the 1st dynasty. If the 1st dynasty ended about 1746–45, the first king dated about 2045–44 to 2032–31. This would accord with the Assyrian statements.

Some modern authorities hold that a fixed dating, not based on the king-lists, can be secured from tablets dealing with observations of Venus. From an entry for the sixth year of Ammizaduga they calculate certain astronomical possibilities, and check the date obtained—one out of four or five possible—by calculations as to the probable period of the date-harvest. Arguing on these lines they hold the sixth year of Ammizaduga to be 1916–15, which would place the commencement of the 1st dynasty in 2170, its close in 1871; another, arguing on the same lines, would date these events 2049–1750. The former, if correct, will necessitate the abandonment of a great deal of Babylonian historical writing as worthless; the question is at present open, and scholars differ by some 120 to 130 years for this period.

Accepting the dating 2045–1745, admittedly open to a margin of error, for the 1st dynasty as fairly accurate, the date lists for the kings' reigns provide an accurate scheme which correct the king-lists in many places. These date-lists arose from the custom of naming a year by some event; in some cases the event was one of religious importance, and may actually have taken place in the year so named, but where military campaigns are mentioned the event probably belongs to the previous year. These date lists establish a synchronism between Hammurabi and Rim-Sin which leads to a date about 2175 for the commencement of the rival dynasties of Isin and Larsa, subject to an error not greater than the date given for the 1st dynasty. Similarly, the 3rd dynasty of Ur of which date-lists are extant may be dated 2282-2175 with the same error. Probably less than seven years actually passed between the accession of Utu-khegal, who ended the oppression by the foreign dynasty of Gutium, and Ur-Nammu's assumption of sovereignty in 2282; this places the Gutium dynasty about 2375–2287, with an increased margin of error. Dating earlier than this is a matter of speculation, for the king-lists, which are complete, give figures that cannot be checked, and for earlier dynasties quite impossible reigns are assigned. There is a general probability that Sargon of Agade commenced his reign between 2550 and 2525, and that the 4th dynasty of Kish began to rule not earlier than 2580. An estimate for the 1st dynasty of Ur, the third after the Flood, based upon comparison with objects from Lagash and the generations, would assign a date between 3000 and 2900 for the commencement of that dynasty, the earliest historical kings known belonging to it. (S. Sm.)

HINDU

The early Hindu astronomers selected a period in the course of which a given order of things is completed by the sun, moon and planets returning to the state of conjunction from which they started. This is known as the Great age of 4,320,000 sidereal solar years, the aggregate of the *Krita* or Golden age, the *Trēta* or Silver age, the *Dvāpara* or Brazen age, and the *Kali* or Iron age (in which we now are). There is, however, the system of the *Kalpa* or aeon, consisting of 1,000 (or 1,008) Great ages.

The Hindus now recognize three standard sidereal solar years determined in that manner. (1) A year of 365 days 6 hours 12 min. 30 sec. according to the *Āryabhaṭīya*, otherwise called the *First Ārya-Siddhānta*, which was written by the astronomer Āryabhaṭa (b. A.D. 476); this year is used in the Tamil and Malayālam districts, and in Ceylon. (2) A year of 365 days 6 hours 12 min. 30·915 sec. according to the *Rājamṛigā ka*, a treatise based on the *Brāhma-Siddhānta* of Brahmagupta (b. A.D. 598) and attributed to king Bhōja, of which the epoch, the point of time used in it for calculations, falls in A.D. 1042: this year is used in parts of Gujarāt (Bombay) and in Rājputānā and other western parts of Northern India. (3) A year of 365 days 6 hours 12 min. 36·56 sec. according to the present *Sūrya-Siddhānta*, a work of unknown authorship which dates from probably about A.D. 1000: this year is used in almost all the other parts of India. According to modern science, the true mean sidereal solar year measures 365 days 6 hours 9 min. 9·6 sec., and the mean tropical year measures 365 days 5 hours 48 min. 46·054440 seconds.

The result of the use of this sidereal solar year is that the beginning of the Hindu astronomical solar year, and with it the civil solar year and the lunar year and the nominal incidence of the seasons, has always been, and still is, travelling slowly forward in our calendar year by an amount which varies according to the particular authority. For instance, Āryabhaṭa's year exceeds the Julian year by 12 min. 30 seconds. This amounts to exactly one day in 115½ years, and five days in 576 years. Thus, if we take the longer period and confine ourselves to a time when the Julian calendar (old style) was in use, according to Āryabhaṭa the Mesha-saṁkrānti began to occur in A.D. 603 on March 20 and in A.D. 1179 on March 25. The intermediate advances arrange themselves into four steps of one day each in 116 years, followed by one step of one day in 112 years: thus, the Mesha-saṁkrānti began to occur on March 21 in A.D. 719, on March 22 in A.D. 835, on March 23 in A.D. 951, and on March 24 in A.D. 1067 (whence 112 years take us to March 25 in A.D. 1179). It is now occurring sometimes on April 11, sometimes on the 12th; having first come to the 12th in A.D. 1871. (*See* CALENDAR: *Hindu.*)

Eras.—The Kalachuri or Chēdi era, commencing in A.D. 248 or 249, is known best from inscriptional records, which range from the 10th to the 13th century A.D., of the Kalachuri kings of the Chēdi country in Central India; and from them it derived its name. In earlier times, this era was well established, without any appellation, in Western India, in Gujarāt and the Ṭhāṇa district of Bombay, where it was used by kings and princes of the Chalukya, Gurjara, Sēndraka, Kaṭachchuri and Traikūṭaka families. It is traced back there to A.D. 457, to the reign of a Traikūṭaka king named Dahrasēna. Beyond that point, we have at present no certain knowledge about it. But it seems probable that its founder was an Ābhīra king Īśvarasēna, or his father Śivadatta, who was reigning at Nāsik about A.D. 248–249.

The Gupta era, commencing in A.D. 320, was founded by Chandragupta I., the first paramount king in the great Gupta dynasty of Northern India. When the Guptas passed away, their reckoning was taken over by the Maitraka kings of Valabhī, who succeeded them in Kāṭhiāwār and some of the neighbouring territories; and so it became also known as the Valabhī era.

From Halsī in the Belgaum district, Bombay, we have a record of the Kadamba king Kākusthavarman, which was framed during the time when he was the Yuvarāja or anointed successor to the sovereignty, and may be referred to about A.D. 500. It is dated in "the eightieth victorious year," and thus indicates the preservation of a reckoning running from the foundation of the Kadamba dynasty by Mayūrāvarman, the great-grandfather of Kākusthavarman. But no other evidence of the existence of this era has been obtained.

The records of the Gāṅga kings of Kaliṅganagara, which is the modern Mukhaliṅgam-Nagarikaṭakam in the Gañjām district, Madras, show the existence of a Gāṅga era, which ran for at any rate 254 years. And various details in the inscriptions enable us to trace the origin of the Gāṅga kings to Western India, and to place the initial point of their reckoning in A.D. 590, when a certain Satyāśraya-Dhruvarāja-Indravarman, an ancestor and probably the grandfather of the first Gāṅga king Rājasiṁha-Indravarman I., commenced to govern a large province in the Koṅkaṇ under the Chalukya king Kīrtivarman I.

An era beginning in A.D. 605 or 606 was founded in Northern India by the great king Harshavardhana, who reigned first at Ṭhāṇēsar and then at Kanauj, and who was the third sovereign in a dynasty which traced its origin to a prince named Naravardhana. This era continued in use for apparently four centuries after Harshavardhana, though his line ended with him.

The inscriptions assert that the Western Chālukya king Vikrama or Vikramāditya VI. of Kalyāṇi in the Nizam's dominions, who reigned from A.D. 1076 to 1126, abolished the use of the Śaka era in his dominions in favour of an era named after himself. He or his ministers adopted, for the first time in that dynasty, the system of regnal years, according to which, while the Śaka era also remained in use, most of the records of his time are dated, not in that era, but in the year so-and-so of the Chālukya-Vikrama-kāla or Chālukya-Vikrama-varsha, "the time or years of the Chālukya Vikrama." There is some evidence that this reckoning survived Vikramāditya VI. for a short time. But his successors introduced their own regnal reckonings; and that prevented it from acquiring permanence.

In Tirhut, there is still used a reckoning which is known as the Lakshmaṇasēna era from the name of the king of Bengal by whom it was founded. The exact initial point of this reckoning appears to be in A.D. 1119. This era prevailed at one time throughout Bengal, from a passage in the *Akbarnāma*, written in A.D. 1584, which specifies the Śaka era as the reckoning of Gujarāt and the Dekkan, the Vikrama era as the reckoning of Mālwā, Delhi and those parts, and the Lakshmaṇasēna era as the reckoning of Bengal.

The Rājyābhishēka-Śaka, "the era of the anointment to the sovereignty," was in use for a time in Western India. It dated from the day Jyaishṭha śukla 13 of the Śaka year of 1597 current, =June 6, A.D. 1674, when Śivajī, the founder of the Marāṭhā kingdom, had himself enthroned.

There are four reckonings which it is difficult at present to class exactly. Two inscriptions of the 15th and 17th centuries, recently brought to notice from Jēsalmēr in Rājputānā, present a reckoning which postulates an initial point in A.D. 624 or in the preceding or the following year, and bears an appellation, Bhāṭika, which seems to be based on the name of the Bhaṭṭi tribe, to which the rulers of Jēsalmēr belong. No historical event is known, referable to that time, which can have given rise to an era. It is possible that the apparent initial date represents an epoch, at the end of the Śaka year 546 or thereabouts, laid down in some astronomical work composed then or soon afterwards and used in the Jēsalmēr territory. But it seems more probable that it is a purely fictitious date, set up by an attempt to evolve an early history of the ruling family.

In the Tinnevelly district of Madras, and in the territories of the same presidency in which the Malayāḷam language prevails, namely, South Kanara below Mangalore, the Malabar district, and the Cochin and Travancore States, there is used a reckoning which is known sometimes as the Kollam or Kōlamba reckoning, sometimes as the era of Paraśurāma. The years of it are solar: in the southern parts of the territory in which it is current, they begin with the month Siṁha; in the northern parts, they begin with the next month, Kanyā. The initial point of the reckoning is in A.D. 825; and the year 1076 commenced in A.D. 1900. The popular view about this reckoning is that it consists of cycles of 1,000 years; that we are now in the fourth cycle; and that the reckoning originated in 1176 B.C. with the mythical Paraśurāma, who exterminated the Kshatriya or warrior caste, and reclaimed the Koṅkaṇ countries, Western India below the Ghauts, from the ocean. But the earliest known date in it, of the year 149, falls in A.D. 973; and the reckoning has run on in continuation of the thousand, instead of beginning afresh in A.D. 1825. It seems probable, therefore, that the reckoning had no existence before A.D. 825. The years are cited sometimes as "the Kollam year (of such-and-such a number)," sometimes as "the year (so-and-

so) after Kollam appeared"; and this suggests that the reckoning may possibly owe its origin to some event occurring in A.D. 825, connected with one or other of the towns and ports named Kollam, on the Malabar coast; perhaps Northern Kollam in the Malabar district, perhaps Southern Kollam, better known as Quilon, in Travancore. But the introduction of Paraśurāma into the matter, which would carry back (let us say) the foundation of Kollam to legendary times, may indicate, rather, a purely imaginative origin. Or, again, since each century of the Kollam reckoning begins in the same year A.D. with a century of the Saptarshi reckoning, this reckoning may be a southern offshoot of the Saptarshi reckoning, or at least may have had the same astrological origin.

In Nēpāl there is a reckoning, known as the Nēwār era and commencing in A.D. 879, which superseded the Gupta and Harsha eras there. One tradition attributes the foundation of it to a king Rāghavadēva; another says that, in the time and with the permission of a king Jayadēvamalla, a merchant named Sākhwāl paid off, by means of wealth acquired from sand which turned into gold, all the debts then existing in the country, and introduced the new era in commemoration of the occurrence. The era may have been founded by some ruler of Nēpāl: but nothing authentic is known about the particular names mentioned in connection with it. This era appears to have been discarded for State and official purposes, in favour of the Śaka era, in A.D. 1768, when the Gūrkhas became masters of Nēpāl; but manuscripts show that in literary circles it has remained in use up to at any rate A.D. 1875.

Inscriptions disclose the use in Kāṭhiāwār and Gujarāt, in the 12th and 13th centuries, of a reckoning, commencing in A.D. 1114, which is known as the *Siṁha-saṁvat*. No historical occurrence is known, on which it can have been based, and the origin of it is obscure.

The eras mentioned above have for the most part served their purposes and died out. But there are three great reckonings, dating from a very respectable antiquity, which have held their own and survived to the present day. These are the Kaliyuga, Vikrama and Śaka eras. The Kaliyuga era is the principal astronomical reckoning of the Hindus. It is frequently, if not generally, shown in the almanacs: but it is not now in practical use for civil purposes; and in previous times we have instances of its use in inscriptions from Southern India, one of A.D. 634, one of A.D. 770, three of the 10th century, and then, from the 12th century onwards, but more particularly from the 14th, a certain number of instances extremely small in comparison with the use of the Vikrama and Śaka eras and other reckonings: from Northern India the earliest known instance is A.D. 1169 or 1170, and the later ones number only four. Its years are by nature sidereal solar years, commencing with the Mēsha-saṁkrānti, the entrance of the sun into the Hindu constellation and sign Mēsha, *i.e.*, Aries (for this and other technical details, *see* above, under the Calendar); but they were probably cited as lunar years in the inscriptional records which present the reckoning; and the almanacs appear to treat them either as Mēshādi civil solar years with solar months, or as Chaitrādi lunar years with lunar months *amānta* (ending with the new-moon) or *pūrṇimānta* (ending with the full-moon) as the case may be, according to the locality. Its initial point lay in 3102 B.C.; and the year 5002 began in A.D. 1900.

The Vikrama Era, the earliest of all the Hindu eras, is the dominant era and the great historical reckoning of Northern India—that territory on the north of the rivers Narbadā and Mahānadī to which part of the country its use has always been practically confined. Like, indeed, the Kaliyuga and Śaka eras, it is freely cited in almanacs in any part of India; and it is sometimes used in the south by immigrants from the north: but it is, by nature, so essentially foreign to the south that the earliest known inscriptional instance of the use of it in Southern India only dates from A.D. 1218, and the very few later instances, prior to the 15th century A.D., come, along with that of A.D. 1218, from the close neighbourhood of the dividing-line between the north and the south. The Vikrama era has never been used for astronomical purposes. Its years are lunar, with lunar months, though sometimes regarded as solar, with solar months, when cited in almanacs of Southern India which present the solar calendar. Originally they were Kārttikādi, with *pūrṇimānta* months (ending with the full-moon). They now exist in the following three varieties: in Kāṭhiāwār and Gujarāt, they are chiefly Kārttikādi, with *amānta* months (ending with the new-moon); and they are shown in this form in almanacs for the other parts of the Bombay Presidency: but there is also found in Kāṭhiāwār and that neighbourhood an Āshāḍhādi variety, commencing with *Āshāḍha śukla* 1, similarly with *amānta* months; in the rest of Northern India, they are Chaitrādi, with *pūrṇimānta* months. The era has its initial point in 58 B.C., and its first civil day, *Kārttika śukla 1*, is Sept. 19, in that year if we determine it with reference to the Hindu Tulā-saṁkrānti, or October 18, if we determine it with reference to the tropical equinox. The years of the three varieties, Chaitrādi, Āshāḍhādi and Kārttikādi, all commence in the same year A.D.; and the year 1958 began in A.D. 1900.

The Śaka Era, which had its origin in the south-west corner of Northern India, is the dominant era and the great historical reckoning of Southern India. It is also the subsidiary astronomical reckoning, largely used, from the 6th century A.D. onwards, in the *Karaṇas*, the works dealing with practical details of the calendar, for laying down epochs or points of time furnishing convenient bases for computation. As a result of that, it came to be used in past times for general purposes also, to a limited extent, in parts of Northern India. And it is now used more or less freely, and is cited in almanacs everywhere. Its years are usually lunar, Chaitrādi, and its months are *pūrṇimānta* (ending with the full-moon) in Northern India, and *amānta* (ending with the new-moon) in Southern India; but in times gone by it was sometimes treated for purposes of calculation as having astronomical solar years, and it is now treated as having Mēshādi civil solar years and solar months in those parts of India where that form of the solar calendar prevails. It has its initial point in A.D. 78; and its first civil day, *Chaitra śukla* 1, is March 3 in that year, as determined with reference either to the Hindu *Masaṁkrānti* or to the entrance of the sun into the tropical Pisces. The year 1823 began in A.D. 1900. (X.)

GREEK

The difficulty besetting Greek chronology, for ancient and modern investigators alike, is the absence, for the earlier periods especially, of a universally understood era, corresponding to our reckoning, B.C. or A.D., or the Muslim, dating from the Hejira. Generally speaking, each state had its own fashion of dating, the usual method of specifying time being to name the annual magistrate who was then in office, as "in the archonship of Apsephion," or a king, priest etc., as "in the reign of King Agis," "in the third year of such a one's tenure of office as priestess of Hera at Argos." This had the grave disadvantage that unless a list of the functionaries in question was available, the date was unintelligible. Hence the best-known of them, the Athenian archons, were most commonly referred to, and often several parallel dates were given, as "when Chrysis had been priestess at Argos for 47 years, Aenesuis being then ephor at Sparta, Pythodorus having yet four months left of his archonship at Athens" (Thucydides, ii.,2,1; = April, 431 B.C.).

Dating by Olympiads.—Gradually, however, the system of dating by Olympiads came into use; this was much more convenient, for the successive celebrations of the festival at Olympia were numbered, not merely named, and the date of the first was conventionally fixed at 776 B.C. of our reckoning. This is due largely to the Alexandrian chronologists, Eratosthenes and the rest, who also drew up the received list of Olympiads. There remained, however, a further difficulty, viz., that various Greek civic years started at different times (*see* CALENDAR: *Greek*); hence there was often used a conventional Olympiad, beginning at the Attic new year, the summer solstice.

The diligence of the Alexandrians resulted in a fairly satisfactory chronology being drawn up for the fully historical periods

i.e., back to about 600 B.C.; from about 500 onwards the number of dates which are seriously doubtful, where the ancient evidence survives, is comparatively small, although minor divergencies are common. But for earlier times, and especially before the beginning of the series of Olympiads (itself not very dependable until Olymp. 50), even the ancient investigators had but few documents to go upon, and were obliged to trust largely to genealogies. By comparing these, they made out a pre-historic and proto-historic chronology, arrived at by allowing three generations to a century. Supposing the genealogies to be authentic and complete, this was a tolerably accurate method; but, although they contained a large element of real tradition, we know enough of them to be sure that they were often interpolated, telescoped by the omission of obscure persons, and otherwise corrupted; so that the earlier dates, such as that of the fall of Troy, must be taken as being, at best, very rough approximations.

The ancient chronologists are represented, for us, by a few historians, such as Diodorus of Sicily, who adopt the annalistic method, and by the Christian chronologists, such as Eusebius and his Latin translator and continuator, S. Jerome, also by later writers, such as Iulius Africanus and Georgius Syncellus. The desire of apologists to prove the Biblical revelation earlier than any other led to the prominence of this branch of learning among them, and to the creation of a new, Hebraizing chronology, made by combining the existing systems with data from the Old Testament. Although uncritical and biased, these writers are of immense value to modern historians of antiquity.

Contribution of Archaeology.—Further help is given by the results of modern archaeology. By careful and minute study of the details of artistic technique, the stratification of material remains of all sorts, the styles of pottery, coins, and other common objects, and comparison with the comparatively few pieces which are in some way dated (*e.g.*, by bearing the name of an owner or dedicator whose epoch is accurately known) it is possible, not only to determine often within a few years and not infrequently with much greater exactness the date of objects found, but also by working backwards to come to reasonable conclusions as to the epoch of many events long previous to documentary history, whereof only vague accounts, largely mythological, had come down to us. Thus, the stratification of the seven cities at Hissarlik, the ancient Troy, has given us a relative chronology, or order of events, for the history of that place; while careful comparison of the finds there with those from Cretan and Mycenaean sites, and of these again with certain Egyptian and other documents which can be at least approximately dated, is gradually enabling us to fix, at any rate within a century or so, the absolute date of Agamemnon's expedition. But at present such dates must be largely provisional, and subject to revision, sometimes of a sweeping kind, in the light of further discoveries. For instance, there are differences of some four centuries in the dating of the Dorian invasion, and even doubts as to its historicity.

It is usual, in giving an ancient date, to extend the Julian period backwards and speak, for instance, of March 2, 290 B.C., meaning the day which would have been so styled if the Greeks of that time had had our calendar and could have foreseen when our era would begin. As these imaginary Julian years frequently cut across the real Greek ones, it is best, when the year only is given, to use a double date and say, for instance, 501/500 B.C.

In dealing with events in late Greek history (Roman and Byzantine epochs) we frequently find non-Greek systems used, such as the Julian calendar. For these, *see* under *Roman Chronology*.

The most important ancient works are cited in the text. For modern authorities, *see* CALENDAR: *Greek*; GREECE: *History*; *Ancient to 146 B.C.*: *General*. Of modern writers, Clinton (*Fasti Hellenici*, 3 vols., 1834) is still useful, although needing much correction in detail.

ROMAN

Roman chronology was in antiquity wholly dependent upon Greek methods, and hence suffered from all the drawbacks of the latter (*see* above, *Greek*), together with a further one, viz., the scarcity and untrustworthiness of native documents. Working along the lines of the Alexandrians, several Roman scholars, notably Varro and Atticus (the friend of Cicero) arrived at chronological schemes for the early history of Rome, whereof considerable fragments have come down to us in the various historians and antiquarians whose works survive, in lists of magistrates such as the fragmentary Fasti Capitolini, and in S. Jerome's chronicle. They are without exception highly untrustworthy for the regal period and the earlier centuries of the Republic (*see* ROME: *Ancient History*), but at least provide us with an epoch by which to reckon: that from the conventional date (753 B.C. of our reckoning) of the foundation of Rome.

Founding of Rome.—Even this date was by no means a matter on which unanimity was reached; that given is the one which ultimately found most favour, and to which the majority of ancient authors refer when they use the expression *a.u.c.* (*ab urbe condita*, or *anno urbis conditae*). The official method of dating was by consuls, as *M. Messalla et M. Pupio Pisone consulibus* (abbreviated *cos.* or *coss.*), "in the consulship of Marcus Messalla and Marcus Pupius Piso" (Caesar, *de bell. Gall.*, 1, 2, 1 (61 B.C.). This never quite went out of use; but under the empire, official documents emanating from the emperors or referring to them reckoned by their years of tribunician power, to which were frequently added other, less regularly recurring, distinctions, such as the consulate or the salutation as *imperator*, *e.g.*, *Imperator Caesar Vespasianus Augustus pontifex maximus, tribuniciae potestatis viiii, imp(erator) xiix, consul viii, i.e.*, "Vespasian (name and titles in full), in the ninth year of his tribunician power, having been saluted *imperator* 18 times, consul for the eighth time" (A.D. 77; from an official letter *C.I.L., II*, 1423). As, however, documents relating to the emperors are very numerous, this method of dating seldom raises much difficulty; our list of consuls also, for the fully historical periods, is tolerably complete. Naturally, in dealing with pre-Caesarian years (*see* CALENDAR: *Roman*) calculations more or less elaborate are needed to convert the year *urbis conditae* into the conventional Julian year (*see* above, *Greek*). These are based on a few facts, such as the mention of an eclipse or other event which we can date accurately. One such eclipse was that of the sun on Oct. 19, 202 B.C.; we gather from various authors that its civic date was about the beginning of December, and this enables us to calculate the condition of the calendar at that time.

Julian Calendar.—The reformed calendar of Julius Caesar was not imposed by Rome on her empire, but naturally it was widely adopted in various modifications. It became the calendar of Christian Rome and also of Constantinople; but gradually a change was made in the era; the supposed date of the birth of Christ replacing that of the foundation of the city (Christian or Dionysian era). This, however, was very slow to win official recognition, despite its convenience; Charlemagne appears to have been the first secular authority to use it. Before that, Christian chronologists used frequently to reckon in years of Abraham, *i.e.*, from his birth, which was placed by Eusebius at a date corresponding to Oct. 2016 B.C.

More important for the determining of Roman imperial dates, than the former, and for some of the later Republican dates also, are the provincial eras and the indictions. It was a wide-spread custom in Hellenistic times to count years from some notable event. The accession of the reigning king was, and continued to be, commonly used, and this, as we have seen, was followed by the emperors; but the Seleucidae and their subjects counted from 312/11 B.C., the date of Seleucus Nicator's decisive victory at the battle of Gaza and his capture of Babylon. In like manner a few Roman chronologists counted from 45 B.C., the date of the Julian reform; and Spain had an era of its own, beginning with 38 B.C., a date chosen for no very obvious reason. Again, several independent cities, such as Antioch, had local eras. When, therefore, we find a year mentioned in an inscription or other piece of evidence, it is necessary to know where this was written, and thus whether the Seleucid era, or that of Spain, or Antioch, or some other place, is meant; or, if the author be a historian, whether he may be using some peculiar era of his own, counting, for example, from the date which he accepts for the fall of Troy, or from the death of Alexander the Great.

The indictions are late, but important for late events, for they

appear in all manner of official documents, ecclesiastical and secular. Properly, *indictio* means an assessment of taxes; *nec novis indictionibus pressi ad vetera tributa deficiunt,* says the younger Pliny (*Paneg.* 29), "the provincials are not so ground down with fresh exactions as to be unable even to pay the old taxes." Under Diocletian, a five-yearly assessment was ordered, and three of these periods grouped together made what was now called an indiction. One authority traces this arrangement back to comparatively early times, making the first indiction begin in 49 B.C.; but the real date seems to be A.D. 297, although even at the beginning of the empire the germ of such a system existed in Egypt. Its chronological importance is, that it provided a means of dating, without mentioning the several emperors who, by Diocletian's arrangement, ruled simultaneously. A disadvantage was that the cycle began on different days at different times and places. Despite these differences, and the fact that *indictio* meant now the whole cycle, now a year of it, it remained in use until the middle ages, and here and there even later.

See CHRONOLOGY: *Greek;* CALENDAR: *Greek*; CALENDAR: *Roman;* also Clinton, *Fasti Romani,* vol. i., 1845, vol. ii., 1850; Seeck, art. "Indictio," in Pauly-Wissowa, *Realencyclopädie,* and literature there cited. (H. J. R.)

JEWISH

The era which is in present vogue among Jews (*Anno Mundi, li-yitzirah* or *libriath olam,* from the creation of the world) appears not to have come into popular use before the 9th century, though possibly it may have been known to learned writers earlier. The era is supposed to begin, according to the mnemonic *Beharad,* at the beginning of the lunar cycle (*see* CALENDAR: *Jewish*) on the night between Sunday and Monday, Oct. 7, 3761 B.C., at 11 hours 11⅓ minutes P.M. This is indicated by *be* (*beth,* two, *i.e.,* 2nd day of week), *ha* (*he,* five, *i.e.,* fifth hour after sunset) and *Rad* (*Resh, dalet,* 204 minims after the hour). Rühl's theory that this era existed already in A.D. 222 is disputed by Poznanski on strong grounds. In the Bible various eras occur, *e.g.,* the Flood, the Exodus, the Earthquake in the days of King Uzziah, the regnal years of monarchs and the Babylonian exile. During the exile and after, Jews reckoned by the years of the Persian kings. Such reckonings occur not only in the Bible (*e.g.,* Daniel viii., 1) but also in the Assouan papyri. After Alexander, the Jews employed the Seleucid era (called *Minyan Shetaroth,* or era of deeds, since legal deeds were dated by this era). So great was the influence exerted by Alexander, that this era persisted in the East till the 16th century, and is still not extinct in south Arabia. This is the only era of antiquity that has survived. Others, which fell into disuse, were the Maccabaean eras, dating from the accession of each prince, and the national era (143–142 B.C.), when Judaea became free under Simon. That the era described in Jubilees (*see* CALENDAR: *Jewish*) was other than hypothetical, is probable. Dates have also been reckoned from the fall of the second Temple (*Le-Ḥorban hab-bayyith*). The equation of the eras is as follows: 1 after destruction = A.M. 3831 = 383 Seleucid = A.D. 71. Jewish chronology falls into two periods, biblical and post biblical. With the latter alone is this article concerned; for the former *see* BIBLE: *Old Testament: Chronology* and *New Testament: Chronology.* The earliest Jewish chronologies have not survived. Demetrius, a Jew of Alexandria, wrote a treatise in which he endeavoured to deduce the dates of Hebrew history from the Scriptures. Of this work only a very few remnants are extant; they have been published by C. Müller (*Fragmenta Hist. Graecorum,* iii. 214–217). The *Book of Jubilees,* written in the second pre-Christian century, subordinates chronology to its peculiar views on the calendar and theology. For present purposes Josephus must be left out of account, for chronology and history are separate studies. The most important and the earliest of all surviving chronologies is the *Seder 'Olam Rabbah.* This Hebrew book is mentioned in the Talmud; the author and date are unknown, but the authorities cited in the book belong almost exclusively to the 2nd century A.D. According to R. Johanan, the work was transmitted by R. Jose ben Halafta, a pupil of Aqiba, and it is possible that this tradition is correct. The author was possibly the first to make use of the era of Creation. Owing to defective sources he makes many errors in the Persian period. The chronology extends from the creation of Adam to Bar Kochba's fight for liberty in Hadrian's days, but the period from Alexander to Hadrian is compressed into the end of one chapter. The best edition is that of B. Ratner (Wilna, 1897). Various Latin translations exist (*vide* bibliography in *Jewish Encyclopedia, s.v.*).

The *Seder 'Olām Zūta,* a smaller work, was written probably in the 8th century; it completes the *Rabbah* and is based on it. The object of the book, which enumerates the 39 generations of Babylonian exitarchs, is to show that the latter were lineal descendants of David. The best text is that of Neubauer, *Mediaeval Jewish Chronicles,* ii., 67.

Megillat Ta'anith, or scroll of Fasting, is a chronicle rather than a chronology, since the events are grouped according to the months of the year and not in chronological sequence. The book enumerates 35 eventful days in five groups: I., pre-Maccabaean; II., Maccabaean; III., pre-Sadducean; IV., pre-Roman; V., the Diaspora. The author was probably, as stated in the Talmud (Sabbath 13 *b*), Hananya ben Hezekiah of the family of Garon, and the date would be about A.D. 7. A Latin translation exists (*vide* bibliography, *s.v.* in *Jewish Encyclopedia,* to which add the edition of Solomon Zeitlin, New York, 1922).

Tanna debe Eliyahu, a composite Midrash finally redacted in the 10th century, can scarcely be termed a chronology, since the underlying theme is the growth of the world-system; human history is arranged in *Shiṭṭōth* (series) in order to bring the moral into prominence. The absence of dates excludes this book from the category of chronology proper, although it contains much historical information.

For modern purposes the best chronology is that at the end of H. Graetz's *History of the Jews* in the American edition. Others are included in the bibliography in the *Jewish Encyclopedia, s.v.* Chronology. *See* also M. L. Margolis and A. Marx, *History of Jewish People* (1927). (H. M. J. L.)

MAYA AND MEXICAN

For technical terms relating to the calendar, which must be used to explain the chronology, the reader is referred to article CALENDAR: *Maya and Mexican.*

Maya: The Long Count.—The Maya calendar is based upon a year of 365 days, but it seems clear that the Mayas themselves recognized no such period. In their view 365 days was one tun (360-day period) and five days, and they so expressed the distance from a month-day in one year to the same month-day in the following year; *e.g.,* from 9 Imix 10 Zip to 10 Cimi 10 Zip. They never used a year of 365 days in counting the distance in time from one date to another. No glyph for the 365-day year is found, and there is no word with that meaning in the Books of Chilan Balam. It has been stated that haab meant 365-day year, but in fact it means tun (360-day period). All authorities agree, however, as to the method of counting time. The units used are the kin or day, the uinal of 20 days, the tun of 18 uinals, the katun of 20 tuns, and the cycle of 20 katuns. The Maya name for the cycle is unknown, and until proof is available it is undesirable to give it a hypothetical Maya name. In transcribing Maya numerals the numbers are written with a dash between each. Thus 9–10– 6– 5– 9 means 9 cycles, 10 katuns, 6 tuns, 5 uinals, and 9 kins. By this method the Maya counted the time elapsed from a certain day, 4 Ahau 8 Cumhu, which was the starting-point of their era, and thereby fixed dates in the Long Count, as the Maya era is called. What is called an Initial Series shows the position of a date in the Long Count. Thus 8 Muluc 2 Zip will recur every 52 years, but if it is expressed as an Initial Series date, 9–10– 6– 5– 9, 8 Muluc 2 Zip, its position in time is fixed, as its distance from the starting-point of the Long Count is given. In the Inscriptions an Initial Series always begins the inscription (hence the name) and commences with an "introducing glyph" which appears merely to mean "This is an Initial Series." Then follow the Maya numerals written in descending order, that is commencing with the largest period (cycle) and ending with the kin, and then the terminal date (in the above example, 8 Muluc

2 Zip). More often than not, the day number and day name (as 8 Muluc) are separated from the month day (as 2 Zip) by a Supplementary Series. In such cases the month day regularly follows the last glyph of the Supplementary Series. A date which is not fixed in the Long Count is called a "Calendar Round date," as it can recur every 52 years.

Another method of giving dates is by "period-endings." This somewhat resembles the European method of giving the last two figures of the year without the century. Thus '98 may mean 1798 or 1898, etc., recurring every 100 years. But the Maya method differs in that it always denotes a certain day instead of a larger period such as a year, and further it is a day terminating a certain round number. It is as if the European method only denoted Dec. 31, and then only when it ended a decade or century. The most usual period-ending is the katun-ending. This is expressed by (1) a glyph meaning "ending," (2) the number of the katun, (3) the Calendar Round date on which a katun of such a number ended. Example: "Ending Katun 13, 8 Ahau 8 Uo." Such a date cannot occur again in the Long Count for 374,400 years, so it is fixed as effectually as if the Initial Series had been given. The "ending sign" may be omitted. Less common are cycle-ending dates, as "2 Ahau 3 Uayeb ending Cycle 2." These cannot recur for 748,800 years. Very common are the lahuntun-endings, expressed by a special glyph meaning "end of Tun 10" together with the Calendar Round date. This means Tun 10 from the last katun-ending. These cannot recur for 18,720 years. Also common are the hotun-endings, expressed by a special glyph meaning "end of Tun 5" and the Calendar Round date. This Tun 5 may mean either Tun 5 from the last katun or Tun 5 from the last lahuntun (therefore Tun 15 from the last katun). These cannot recur for 9,360 years and are, therefore, practically as much fixed as the others. Example: "4 Ahau 13 Mol, Hotun." This must be 9–11–15– 0– 0 4 Ahau 13 Mol, because that date does not end Tun 5 or 15 elsewhere in cycles 8, 9 or 10 or indeed for 9,360 years before or after. No other satisfactory case of tun-ending occurs in the old empire except the 13- tun ending, expressed by glyphs meaning "ending Tun 13" and the Calendar Round date. These cannot recur for 18,720 years. As all period-endings denote the ends of even periods in the Long Count which itself starts from 4 Ahau 8 Cumhu, they must themselves all end on a day Ahau.

Many dates in the inscriptions are connected with other dates by "Secondary Series" numbers. If a date is connected by a Secondary Series with another date which is fixed in the Long Count, then the former date is called a Secondary Series date and is, of course, itself fixed in the Long Count, as it can be calculated by the Secondary Series from the known date. Example: "6 Imix 19 Zotz, connected by Secondary Series of 2–1–13–19 with 4 Ahau 13 Mol." But the latter is fixed by a period-ending in same inscription as 9–11–15– 0– 0 4 Ahau 13 Mol. so the former is 9–9–13– 4– 1 6 Imix 19 Zotz. But dates may be connected by a Secondary Series, and neither of them may be fixed in the Long Count, in which case both are merely Calendar Round dates.

All Initial Series in the Dresden Codex, and all except two, in the inscriptions, start from 4 Ahau 8 Cumhu. But there are two Initial Series in the inscriptions which start from a date 4 Ahau 8 Zotz which occurred 13 cycles before the date 4 Ahau 8 Cumhu, the starting-point of all the rest. In the Dresden Codex a "great cycle" is used containing 20 cycles. Dr. Sylvanus G. Morley shows that this was used in the inscriptions, and also a great-great cycle of 400 cycles, and a great-great-great cycle of 8,000 cycles. This has been confirmed by Long's discovery of a new interpretation of an inscription at Palenque.

It will be noted that all the Maya time periods (except the tun) are each 20 times the next lower one. In the inscriptions these numbers are written with the glyphs for the periods as well as the numbers. Thus 9–10– 0– 0– 0, if an Initial Series, is expressed by glyphs reading 9 cycles, 10 katuns, 0 tuns, 0 uinals, 0 kins. This is similar to the usual mode of writing measures; *e.g.*, 10ft. 11in. Secondary Series are written in the same manner except that in them the lowest denomination (kin) comes first and the highest last. There are only three or four Secondary Series which do not follow this order, all at Palenque. But in the Dresden Codex the glyphs for the periods are omitted, and the value of the numbers depends upon position alone, as in the Arabic numerals.

Cyrus Thomas remarks that there is nothing to show that the 4 Ahau 8 Cumhu to which the Initial Series count back is the same in actual time in all. This is so, because 4 Ahau 8 Cumhu will recur every 52 years. But Thomas agrees that the assumption that it is the same actual day in all gives the most credible result, as this makes the terminal dates of the inscriptions fall within a reasonable distance of each other, and no doubt the assumption is correct. The earliest dated monument is Stela 9 at Uaxactun, 8–14–10–13–15 and the latest in the old empire is Stela 12 at the same site and is 10– 3– 0– 0– 0. This gives an extreme range of 1– 8– 9– 4– 5 (about 561 years), quite a probable time for any phase of civilization to last. But since the Maya erected the first dated monument about 3,443 years after the beginning of their era, it is clear that 4 Ahau 8 Cumhu represents no historical event and must have fallen long before there was any Maya civilization. Like the Julian period used by astronomers, it was a date calculated by skilled chronologists long after the invention of the calendar, doubtless with the object of harmonizing lesser periods.

But in general the range of Maya dates is even shorter. Many of the monuments record only one date, and where there are several the last date, or at least the last period-ending, seems generally to be the contemporaneous one. Now the dated monuments are very rare in cycle 8, more numerous, but still confined to a few sites, from 9– 0– 0– 0– 0 to 9– 10– 0– 0 0, become very numerous from 9–10– 0– 0– 0– to 9–15– 0– 0– 0, increase much more after 9–15– 0– 0– 0, reach a maximum in 9–18– 0– 0– 0, and then suddenly diminish, becoming much fewer after 9–19– 0– 0– 0, and ceasing after 10– 3– 0– 0– 0. The style of the monuments likewise shews a steady advance in art up to about 9–18– 0– 0– 0. Change is also observable in the method of dating. In cycle 8 the monuments were erected on casual dates which did not end any tun or other time period, and the dates were usually shewn by Initial Series, but early in cycle 9 the practice was adopted of setting up the monuments to mark each hotun. Unfortunately hotun is used by Maya scholars in this case to mean the end of either a katun, lahuntun, or hotun, that is, it means any number of tuns of the Long Count which is divisible by five. Initial Series were still used, and at about 9– 8–15– 0– 0 the practice began of giving several dates on a monument besides the Initial Series, the last one marking the hotun. After 9–10– 0– 0– 0 monuments dated by period-endings became fairly frequent, and after 9–15– 0– 0– 0 the Initial Series became rarer, and monuments were dated mostly by period-endings or Calendar Round dates. Geographically we also see change. The old empire area was roughly triangular with Uaxactun and Tikal in the north-east, Copan and Quirigua in the south-east, and Piedras Negras in the west. Uaxactun and its neighbour, Uoluntun, alone show dates in cycle 8. In the first half of cycle 9 the monuments are almost confined to Uaxactun, Tikal, Copan and Piedras Negras, outliers in the area, while after 9–10– 0– 0– 0 they are numerous everywhere till 9–18– 0– 0– 0, when they cease at Piedras Negras and the west, ceasing at Quirigua and Copan and the south-west after 9–19– 0– 0– 0. Some new cities appear towards the close of cycle 9 in the north-east, and the closing date is at Uaxactun and Xultun near it. It is noteworthy that Uaxactun and Tikal, though at the north-east of the old empire, are almost in the centre of the whole Maya area if we consider the old and new empire territories together, and these sites were probably the original seats of the Maya.

The New Empire.—The Long Count was wanting in the new empire. Instead they used the U Kahlay Katunob, which was a simplification of the older period-ending method. The cycle had entirely dropped out of use, and the only periods were the katun and the tun, the katun being the more important. The katuns were cited by the day Ahau with its day number on which they ended. Thus "Katun 13 Ahau" or simply "13 Ahau." Such a date can recur every 13 katuns (about 256 years) because in

that time the 13 day numbers will be exhausted. The order of succession is 13. 11. 9. 7. 5. 3. 1, 12. 10. 8. 6. 4. 2. Often nothing was mentioned save the katun in which the event occurred, so that not only could the katun recur about every 256 years, but the event might have occurred anywhere within the katun, leaving about 20 years uncertainty. At times an event is described as occurring in tun so-and-so of such a katun, thus fixing it within a period of 360 days within the katun. But if the Calendar Round date is given as well, as *e.g.*, "Katun 13 Ahau, Tun 13, 9 Imix 18 Zip," then (depending upon what date it is) the date can either only occur once in 18,720 years or can occur twice in that time, at intervals of 7,436 years and 11,284 years respectively.

Correlations.—The state of knowledge about the Maya of the old empire has no parallel in archaeology. While on the one hand we do not even know the names of the peoples who erected the monuments, much less their history, nor even if they spoke Maya, seeing that all knowledge of the calendar is based upon Landa's account of the new empire, yet so accurate were their dates that it is possible to date the monuments with regard to each other to the exact day. But widely different views are held by scholars as to the correlation with Christian chronology. The principal elements of the problem are: (1) correlation of the old and new empire chronologies, (2) correlation of the new empire and Christian chronologies, (3) correlation with astronomical discoveries of Teeple. (1) If the month-days on which the katuns of the new empire ended had been stated, there would have been an absolute correlation with the old empire. A tun ends on the same day number every 13 tuns, but will end on the same month-day only every 73 tuns, and on the same day number and month-day only every 949 tuns. Similarly a katun will only end on the same day number and month-day every 949 katuns (18,720 years). But as the new empire method did not state the month, the Katun 13 Ahau which occurred in the 16th century is identified with various katuns of the Long Count by different writers. The Books of Chilan Balam carry back the new empire chronology to about A.D. 163. Mr. J. Eric Thompson alone shortens this. (2) Opinions differ as to what year in the 16th century a katun 13 Ahau ended in, so the new empire chronology is only loosely correlated with Christian chronology within the limits of about a katun. The Maya year was a shifting one and Landa says that in his time Pop began on July 16 O.S. This was in or near 1553. No correlation can stand which does not agree with Landa's statement, consequently all are ruled out but the three given below. (3) Teeple shows certain lunar and Venus dates agreeing with Thompson, but probably the last word has not yet been said on this subject.

The Bowditch correlation depends on a statement as to the month-day and has considerable historical evidence in its favour. Thompson's correlation depends on another statement as to the month-day and raises some difficulties owing to the shortness of its chronology. Dr. Herbert J. Spinden's correlation is at variance with both of these month-dates and also with Teeple's results. Moreover, the astronomical observations on which he relies have been shown by further measurement to be incorrect. The dates of 4 Ahau 8 Cumhu in these correlations are in the Gregorian Calendar (astronomical reckoning):—

Bowditch, Joyce and Long	Feb. 10 3641 B.C.
Spinden	Oct. 14 3373 B.C.
Thompson	Aug. 13 3113 B.C.

As the Maya chronology was the only efficient one in pre-Columbian America it would, if fixed, throw much light on that of America as a whole. Excavation of Maya sites has yielded objects obtained in trade from both northwards and southwards, so that if the correlation was established, the period when these neighbouring cultures flourished could be approximated.

Solving Dates.—A word in conclusion on solving dates. Given such a series as 9–10–6–5–9 and that its starting-point is a known date such as say 4 Ahau 8 Cumhu, the day name can at once be determined by counting the kin number (in this case 9) from the starting-point; thus 9 days from Ahau will reach Muluc. But the finding of the day number and the month-day is a more difficult matter. It is possible to reduce the whole series to single days and then find the day number by dividing by 13 and counting the remainder forward from the day number of the starting point, similarly to find the month-day by dividing the total number of days by 365 and counting forward the remainder from the month-day of the starting-point. But the student is advised not to use this time-wasting method. Many problems can be solved by tables, of which the best are J. T. Goodman's and those of Mr. Thomas A. Joyce, but not all cases can be directly done by tables, and though they are valuable for checking results, it is well to be able to calculate independently of them. By far the best rule is that of Mr. Raymond K. Morley (*see* Bibliography), by which all series can be quickly calculated without any tables.

Cakchiquel Calendar.—This is the only era found in ancient America except the Maya. It was a pure vigesimal count, the units being the *kih* or day; the *vinak* (meaning "twenty") or 20 *kih*, the *a* or 20 *vinak*, and the *may* or 20 *a*. No higher units are known or were required, as the era only started from the day 11 Ah, the date of the revolt of the Tukuche tribe, equivalent to May 20 1493 O.S. This era is altogether unique, not only from its purely vigesimal character, but also that it only commenced in the lifetime of persons who were living at the Spanish conquest. No hint of any other era appears in the Annals, before the revolt, but the use of the special words such as *a* and *may* shows that such a mode of counting from some other epoch or epochs had been previously known. The Cakchiquel, living southwards of the old empire, like the Yucatan Maya to the north of it, used a later simplification of the older time counts. Dates were expressed thus: On 1 Ah was completed 1 *may* and 1 *a*; after the revolt, on 12 Camey (a certain event occurred). Sometimes the number of *vinak* and *kih* was also given.

Mexican Calendar.—There was no chronological system beyond the calendar round. The codices show no means of giving the numbers of years elapsed from one date to another except the clumsy one of stating the year-bearers of all the intervening years. The calendar round began with the year 2 Acatl, in which year the great festival of the "year-binding," *xiuhmolpilli*, was held. The codices denote such a year by a special sign along with the year-bearer, but this is merely the same thing as noting the occurrence of such an event in that year. The sign for the year-binding was never used as an arithmetical sign to show that 52 years or a multiple thereof had elapsed. To do this they had to set out all the individual years. Naturally, there is much confusion in Mexican history and the same event is placed by different authorities at varying numbers of calendar rounds before the Spanish conquest. Mexico surrendered to Cortez on the day 1 Coatl, year 3 Calli, which was Aug. 13 1521 O.S. This was 3 Xocouetzi, as the year-bearers were taken from 1 Toxcatl instead of from the first month of the year. The explanation is probably that the monthly festivals were displaced in the shifting calendar to agree with the seasons, but this question is very obscure.

BIBLIOGRAPHY.—C. P. Bowditch, *The Numeration, Calendar Systems, and Astronomical Knowledge of the Mayas* (Cambridge, U.S.A. 1910); T. A. Joyce, *Mexican Archaeology* (London, 1914), and *Guide to the Maudslay Collections of Maya Sculptures* (British Museum, 1923); S. G. Morley, *An Introduction to the Study of Maya Hieroglyphs* (Washington, Bureau of American Ethnology, 1915), and *The Inscriptions at Copan* (Washington, Carnegie Institution, 1920); R. K. Morley, "Computations for the Maya Calendar" in *American Anthropologist* (1918); R. C. E. Long, "Maya and Christian Chronology," *Journal Royal Anthropological Institute* (1923), "The Age of the Maya Calendar," *Journal Royal Anthropological Institute* (1924), "Maya High Numbers," Man. No. 39 (1923), "The Bowditch and Morley Correlations of Maya Chronology," Man. No. 2 (1925); J. E. Teeple, "Maya Inscriptions, Glyphs," C. D. & E. of the Supplementary Series, and "Further Notes on the Supplementary Series," in *American Anthropologist* (1925); also "Maya Inscriptions, The Venus Calendar and another Correlation," in *American Anthropologist* (1926); H. J. Spinden, *The Reduction of Mayan Dates* (Cambridge, U.S.A., Peabody Museum); J. E. Thompson, *A Correlation of the Mayan and European Calendars* (Chicago, Field Museum of Natural History, 1927).

The student is recommended to read first Joyce's *Guide*, then his *Mexican Archaeology*, then Morley's *Introduction* (with good bibliography), and then Bowditch. The last two are absolutely essential. Morley's *Copan*, a truly great book, presupposes a knowledge of the subject and contains an extensive bibliography. (R. C. E. L.)

MUSLIM

The Muslim Calendar (*see* CALENDAR: *Muslim*) may evidently be carried on indefinitely by successive addition, provided care be taken to allow for the additional day occurring in bissextile and intercalary years. The purely lunar years of this calendar are partitioned into cycles of 30 years, 19 of which are common years of 354 days each, the remaining 11 being intercalary years having an additional day appended to the last month. The mean length of the year is, therefore, $354\frac{11}{30}$ days (354 days, 8 hours, 48 minutes). This gives $29\frac{1}{2}\frac{8}{3}\frac{1}{0}$ days (29 days, 12 hours, 44 minutes) as a period of mean lunation, and this differs from the astronomical mean lunation by only 2·8 seconds. This small error amounts to a day in about 2,400 years.

To find if a year is intercalary or common, divide it by 30; the quotient will be the number of completed cycles and the remainder will be the year of the current cycle; if this last be one of the numbers 2, 5, 7, 10, 13, 16, 18, 21, 24, 26, 29, the year is intercalary and consists of 355 days; if it be any other number, the year is ordinary.

Year of the current cycle (y)				Number of the period of seven cycles = $\left(\frac{C}{7}\right)_r$						
				0	1	2	3	4	5	6
0	8	..	..	Mon.	Sat.	Thur.	Tues.	Sun.	Frid.	Wed.
1	9	17	25	Frid.	Wed.	Mon.	Sat.	Thur.	Tues.	Sun.
*2	*10	*18	*26	Tues.	Sun.	Frid.	Wed.	Mon.	Sat.	Thur.
3	11	19	27	Sun.	Frid.	Wed.	Mon.	Sat.	Thur.	Tues.
4	12	20	28	Thur.	Tues.	Sun.	Frid.	Wed.	Mon.	Sat.
*5	*13	*21	*29	Mon.	Sat.	Thur.	Tues.	Sun.	Frid.	Wed.
6	14	22	30	Sat.	Thur.	Tues.	Sun.	Frid.	Wed.	Mon.
*7	15	23	..	Wed.	Mon.	Sat.	Thur.	Tues.	Sun.	Frid.
	*16	*24	..	Sun.	Frid.	Wed.	Mon.	Sat.	Thur.	Tues.

To find from this table the day of the week on which any year of the Hejira begins, the rule to be observed will be as follows:—

Rule.—Divide the year of the Hejira by 30; the quotient is the number of cycles, and the remainder is the year of the current cycle. Next divide the number of cycles by 7, and the second remainder will be the Number of the Period, which being found at the top of the table, and the year of the cycle on the left hand, the required day of the week is immediately shown.

The intercalary years of the cycle are distinguished by an asterisk.

For the computation of the Christian date, the ratio of a mean year of the Hejira to a solar year is:

$$\frac{\text{Year of Hejira}}{\text{Mean solar year}} = \frac{354\frac{11}{30}}{365{\cdot}2422} = 0{\cdot}970224.$$

The year 1 began July 16, 622, Old Style, or July 19, 622, according to the New or Gregorian Style. Now the day of the year answering to July 19, is 200, which, in parts of the solar year, is 0·5476, and the number of years elapsed = $Y-1$. Therefore, as the intercalary days are distributed with considerable regularity in both calendars, the date of commencement of the year Y expressed in Gregorian years is:

$$0{\cdot}970224\ (Y-1)+622{\cdot}5476,$$
$$\text{or } 0{\cdot}970224\ Y+621{\cdot}5774.$$

This formula gives the following rule for calculating the date of the commencement of any year of the Hejira, according to the Gregorian or New Style.

Rule.—Multiply 970,224 by the year of the Hejira, cut off six decimals from the product, and add 621·5774. The sum will be the year of the Christian era, and the day of the year will be found by multiplying the decimal figures by 365.

The result may sometimes differ a day from the truth, as the intercalary days do not occur simultaneously; but as the day of the week can always be accurately obtained from the foregoing table, the result can be readily adjusted.

CHRONOMETER. A marine timekeeper, used for determining longitude at sea. The word was originally used to denote any time-measuring instrument. The first instance of its employment in its accepted modern meaning is to be found in Jeremy Thacker's "The Longitudes Examined . . ." (London, 1714). On the Continent the analogous term "chronomètre" is still used to describe any high-class timekeeper, whether for marine purposes or otherwise.

History.—The possibility of determining longitude at sea by the use of a timekeeper was first pointed out by the Flemish astronomer Gemma Frisius, in a work on navigation published at Antwerp in 1530. At that date, however, and for long afterwards, the mechanical difficulties in the way of constructing an accurate marine timekeeper appeared to be insurmountable. The first attempt to put Frisius' suggestion into practice was made in 1662–70 by the celebrated Dutch scientist, Christiaan Huygens, of Zulichem, who constructed several marine timekeepers controlled by pendulums and subjected them to actual tests at sea. It was found that the timekeeping of the machines was quite unreliable, owing to the effects of temperature and of the ship's motion. Many later inventors fared no better, but during 1729–60 John Harrison, a self-taught Yorkshire carpenter, invented and constructed four practical marine timekeepers, with the fourth of which (now preserved, in going order, at Greenwich Observatory) he won the reward of £20,000 offered in 1714 by the British Government for any means of determining a ship's longitude within 30 nautical miles at the end of a six weeks' voyage. It may be noted that a timekeeper fulfilling this condition would have to keep time within three seconds per day—a standard which, at the date when the reward was offered, had not been attained by the best pendulum clocks on shore.

Harrison's mechanism, although unquestionably efficient, was complicated, delicate and costly—the Board of Longitude paid Larcum Kendall, a London watchmaker, £450 for a duplicate of the No. 4 timekeeper. Accordingly, it had little direct effect upon the evolution of the modern chronometer. But in 1765 Pierre Le Roy, of Paris, invented and constructed a marine timekeeper whose mechanism embodied, in an embryonic but perfectly recognizable form, practically all the essential features of the modern chronometer. This machine, or a contemporary duplicate, is preserved in the Conservatoire des Arts et Métiers in Paris. Le Roy's work was followed up by Ferdinand Berthoud in France and by John Arnold and Thomas Earnshaw in England. The last-named produced, as early as 1785, several chronometers which, both in appearance and mechanism, are scarcely distinguishable from the machine of to-day.

Description.—The modern chronometer is, broadly speaking, a large, well-made watch, suspended in gimbals (a set of two bearings at right-angles, connected by a ring) and so poised as to remain horizontal whatever the inclination of the ship. It is thus safeguarded from those alterations of position which slightly affect the timekeeping of even the best watches. In addition, it differs somewhat in its mechanism from an ordinary watch, the spiral balance-spring and lever escapement of the latter being replaced by a helical balance-spring and a spring-detent or "chronometer" escapement. This form of escapement is mechanically superior to any other, and requires no oiling, but it is unsuitable for use in pocket watches, as if stopped it has no tendency to re-start itself. For the purpose of equalizing the force of the mainspring, almost all chronometers are fitted with a device known as a "fusee," which has for some time past been discarded in watches, and their compensation-balances, by which the effects of heat and cold upon their timekeeping are practically nullified, also differ in some respects from the ordinary watch type, as well as being considerably larger and heavier.

Accuracy.—The modern chronometer is capable, with fair usage, of going with what must be regarded, in view of the unfavourable conditions to which it is necessarily exposed on board, as astonishing accuracy. Both during the official tests at Greenwich Observatory (which has been held annually, on practically unaltered lines, from 1844 to 1914) and in their subsequent service afloat, many hundreds of chronometers have shown themselves capable of keeping time in all ordinary variations of temperature for six months at a time with an error not exceeding a second a

day—an amount which, in a month's voyage along the equator, would involve an error in the ship's final position of less than eight nautical miles. (*See* also NAVIGATION.)

U.S. Marine Chronometer.—During the years 1942 to 1944 a marine chronometer of very high precision was developed in the United States by the Hamilton Watch company. In general appearance, this chronometer is like any other, but certain changes have been made in the escapement. The hairspring used is made of nickel steel, similar to elinvar; the balance wheel is uncut and has a stainless steel rim with an invar arm. There are a number of timing screws, as in a watch, which permit very close adjustment of the rate. This chronometer shows a practically uniform variation with temperature, with daily rates at 5° C. and 35° C. differing by only a few tenths of a second. The rate during run-down remains uniform for 48 hours after winding.

See R. T. Gould, *The Marine Chronometer, its History and Development* (1923), a general history of the subject. (R. T. Go.; X.)

CHRYSANTHEMUM, a genus of nearly 300 species of annual or perennial herbs of the family Compositae; popularly the name given to forms of certain old world species of this genus which have been remarkably developed by cultivation. Most varieties of the so-called Chinese and Japanese chrysanthemums extensively grown by gardeners and florists are blended hybrids or other forms derived from *C. morifolium* and *C. indicum*, natives of eastern Asia. Other species of interest to flower growers are *C. coccineum* (pyrethrum), *C. parthenium* (feverfew), and *C. frutescens* (marguerite). Other representatives of the genus are *C. balsamita* (costmary) and *C. leucanthemum* (ox-eye daisy), the latter often a pestiferous weed. The common chrysanthemum has probably been known for at least 2,000 years. In Japan, where it can be traced back many centuries, it is the national flower. Breynius in 1689 was the first European to mention the chrysanthemum, giving it the name of *Matricaria japonica maxima*. Pierre Louis Blancard introduced the first large-flowering chrysanthemum into England in 1789. This first flowered in 1790. Just when the plant was first introduced into the United States is uncertain, although horticultural chrysanthemums were exhibited in Philadelphia in 1827 and in Boston the next year. The work of hybridization was first taken up by Dr. H. P. Walcott and later in the '80s by John Thorpe, who organized the Chrysanthemum Society of America in 1890. The only species of economic importance are certain forms of *C. coccineum*, much grown for the aromatic flower heads, the source of pyrethrum powder, widely used in insecticides. Chrysanthemums are popular with the gardeners, both professional and amateur, as an exhibition flower because of their great size and variety of shape and colour, and also because some varieties are extremely hardy, which permits their use in the perennial garden. Chrysanthemums owe their popularity with commercial florists not so much to their value as a crop as to the fact that they may be planted in the late spring and early summer when the greenhouse otherwise would be empty. Moreover, the chrysanthemum is a quick-maturing crop, many varieties being grown without artificial heat, since they bloom from late August to December.

The cultural requirements for chrysanthemums may be adjusted to many rotation schemes, so that the same greenhouse may be used for growing other floral crops, such as calendulas, sweet peas, stocks, snapdragons, annuals and lilies.

Classification of Types.—(1) *Incurved Chinese types* are nearly globular in form and regular in outline; the florets are smooth, rounded or somewhat toothed at the top, and sufficiently long to form a graceful curve (commercial varieties are Maj. Bonaffon, Mrs. Nellie T. Ross, Citronelle). (2) *Japanese types* are varieties with long loosely arranged florets; the florets may be flat, fluted, quilled or tubulated and may be incurved or reflex. Many exhibition varieties (Mrs. H. S. Firestone, F. E. Nash, Miss Ruth C. Twombly, Majestic) come in this type. (3) *Anemones* have high, neatly formed centres with elongated quilled florets, surrounded by flat, more or less horizontally arranged ray flowers. Examples are Gorza, Chestnut, Mapleleaf. (4) *Pompons* may be somewhat flat or nearly globular, generally very neat and compact, formed of short, flat, fluted or quilled florets. The florets of each bloom are all of one form, such as the varieties Varsity, Co-ed, Baby, Pink Dot and Nuggets. (5) *Singles* are arranged sufficiently close together to form a regular fringe. There may be one or two rows of ray flowers and sometimes as many as three or five. The centres of the florets are always tubular, either short or somewhat elongated. Golden Mensa, Mrs. E. D. Godfrey and Margaret Waite are good examples. (6) *Cascades*, derived from a wild Japanese species, comprise a group of showy pot plants which by pinching make handsome, usually drooping, very floriferous sprays of bloom.

During 1936–38 a group of chrysanthemums was launched under the name of *azaleamum*. Most of them were related to old varieties such as Amelia, etc., with no relationship to azalea.

Propagation.—The chrysanthemum is generally propagated by cuttage, seedage or division. Cuttage is by far the most satisfactory, since insects and diseases may be controlled by the careful selection of clean stock. Plants grown from cuttings make better growth, give better flowers and are easier to stake and tie in the garden. Nearly all chrysanthemums grown in commercial greenhouses are produced from cuttings. Division is practised by many outdoor gardeners. Seedage is practised only by breeders who seek new varieties.

Plants for propagation are packed in flats, benches or cold frames, after the flowering season, and wintered over in either a cold greenhouse or frame. In March or April the strong shoots are ideal for making cuttings 2 to 4 in. long. If aphides are present, the cuttings should be placed in a 1-to-500 or 1-to-800 solution of nicotine sulphate in water before planting. Clean sand is best for rooting cuttings, which should be firmly packed and watered. The bed should be lightly shaded for a few days to prevent wilting.

Wilted cuttings generally die, but if they root the resulting plants are stunted. Syringing on warm days will help to keep the cuttings fresh. A temperature of 50° F. is sufficient, but quicker rooting is obtained if 60° F. is maintained.

When the roots are about ½ in. long the plants should be potted in a fibrous loam soil. If allowed to remain too long in the cutting bed, they become hard and are not responsive to good culture. The plants are usually ready for their permanent quarters by early June or July. A good fibrous, well-drained loam is the ideal soil medium for chrysanthemums. If this soil is packed before planting or directly afterward, the new growth becomes firmer and the internodes shorter. Newly set plants should be watered only lightly, since wet soil is unfavourable for their growth. The tops of the plants may, however, be syringed often to keep them fresh.

The planting distances vary with the different types. Commercial growers vary the planting of the large flowering chrysanthemums as follows: 6 in. by 6 in., 7 in. by 8 in., 7½ in. by 8 in., 10 in. by 10 in. Pompons are planted 12 in. by 12 in. and 12 in. by 15 in. inside, while outdoors 15 in. by 15 in. and 18 in. by 18 in is the general practice.

As soon as the plants are placed they should be staked and tied. The tying should be done as the plant grows so that the stem will remain straight. When the stem becomes 6 in. long the plant should be "topped" (top pinched out), if more than one stem is desired. Topping should continue for small-flowered plants until August. Watering, syringing and tying are of chief importance during the summer months.

The plants should be kept as cool as possible by spraying and syringing and by wetting the walks.

In the late summer and early fall "disbudding" becomes a factor. The first bud to appear is generally the crown bud. This bud will flower early and give a large flower, but the shape, colour and habit are not as desirable for commercial use as are flowers from lateral buds. The crown bud is surrounded by vegetative shoots, one of which may be saved to produce the desired flower bud. The terminal bud of the final shoot is surrounded by other buds, which should be removed if only one large flower is desired.

If the soil is a good composted fibrous loam, no fertilizer should be given until the bud is selected. Thereafter, liquid manure should be given once a week until the buds show colour. Continued

use of any fertilizer, especially those that are too strong, will cause the flowers to "blast" and "burn." The foregoing cultural directions apply equally as well to the chrysanthemums in the garden. Systematic fumigation and the propagation of clean stock are the greatest factors in the prevention and control of pests. Upwards of 500 named varieties of the chrysanthemum are listed in catalogues and horticultural works, and new forms are constantly being produced.

For more extensive details, *see* L. H. Bailey, *The Standard Cyclopedia of Horticulture* (1933); for list of recognized American varieties, *see Standardized Plant Names* (Salem, Mass., 2nd edition, 1939). *See* also E. A. White, *The Chrysanthemum and Its Culture* (1930).

(H. O. Y.; N. Tr.)

CHRYSANTHIUS, Greek philosopher of the 4th century A.D. He was a pupil of Aedesius and an exponent of the mystical side of Neoplatonism (*q.v.*). Invited by the emperor Julian to assist in the scheme for the revival of Hellenism, he declined, probably foreseeing its failure. As high-priest of Lydia he kept the respect of Christians and pagans alike.

CHRYSELEPHANTINE, the architectural term given to statues which were built up on a wooden core, with ivory representing the flesh and gold the drapery (Gr. χρυσός, gold, ἐλέφας, ivory). The most celebrated examples are by Pheidias, the statue of Athena in the Parthenon and of Zeus in the temple at Olympia.

CHRYSENE, a hydrocarbon discovered by Laurent in the high boiling point fractions of coal tar distillate, is produced in small quantity in the distillation of amber, or on passing the vapour of benzyl-α-naphthylmethane through a red-hot tube. When impure, it is of a yellow colour; hence its name (χρύσεος, golden yellow). Chrysene, $C_{18}H_{12}$, crystallizes in colourless plates or octahedra (from benzene), which exhibit a violet fluorescence, and melt at 250° C. It boils at 448° C. Chromic acid in glacial acetic acid solution oxidizes it to chrysoquinone $C_{18}H_{10}O_2$, which, distilled with lead oxide, gives chrysoketone $C_{17}H_{10}O$. *See* A. E. Everest, *The Higher Coal-tar Hydrocarbons* (1927).

CHRYSIPPUS (*c.* 280–206 B.C.), Greek philosopher, third leader of the Stoics, born at Soli, Cilicia (Diog. Laert. vii. 179). He came to Athens and studied possibly under Zeno, certainly under Cleanthes. It is said also that he became a pupil of Arcesilaus and Lacydes, heads of the middle academy. His chief fame rested on his controversies in the academy, for which he was called "the column of the portico." Diogenes Laertius says "without Chrysippus there had been no Porch." Of the 750 treatises with which he is credited only fragments survive. The style is said to have been crabbed, the argument lucid.

See G. H. Hagedorn, *Ethica Chrysippi* (1715); J. F. Richter, *De Chrysippo Stoico fastuoso* (1738); F. Baguet, *De Chrysippi vita doctrina et relinquiis* (1822); C. Petersen, *Philosophiae Chrysippeae fundamenta* (1827); A. B. Krische, *Forschungen auf dem Gebiete der alten Philosophie* (1840); R. Nicolai, *De logicis Chrysippi libris* (1859); R. Hirzel, *Untersuchungen zu Ciceros philosophischen Schriften*, ii (1882); A. Gercke, "Chrysippea" in *Jahrbücher für Philologie*, suppl. vol. xiv (1885); L. Stein, *Die Psychologie der Stoa* (1886); J. E. Sandys, *Hist. Class. Schol.* i, 149; E. Brehier, *Chrysippe* (Les Grands philosophes, Paris, 1910). *See* also Stoics.

CHRYSOBERYL, a yellow or green gem stone, remarkable for its hardness, being exceeded in this respect only by the diamond and corundum. The name suggests that it was formerly regarded as a golden variety of beryl. Its composition is $BeAl_2O_4$ or $BeO.Al_2O_3$. It is yellow or pale green, occasionally passing into shades of dark green and brown. Chrysoberyl is often mistaken by its colour for chrysolite (*q.v.*), and has indeed been termed oriental chrysolite, but it is a much harder and denser mineral. A contrast of their chief characters is as follows:

	Chrysoberyl	Chrysolite
Hardness	8.5	6.5 to 7
Specific gravity	3.65 to 3.75	3.34 to 3.37
Chemical composition	$BeAl_2O_4$	Mg_2SiO_4

Chrysoberyl is not infrequently cloudy, opalescent and chatoyant, and is then known as "cymophane" (Gr. κυμα, cloud). The cloudiness is referable to the presence of multitudes of microscopic cavities. Some of the cymophane, when cut with a convex surface, forms the most valuable kind of cat's-eye (*see* Cat's-eye). A remarkable dichroic variety of chrysoberyl is alexandrite (*q.v.*).

Most chrysoberyl comes from Brazil, chiefly from the district of Minas Novas in the state of Minas Gerais, where it occurs as small water-worn pebbles. The cymophane is mostly from the gem gravels of Ceylon. Chrysoberyl is a constituent of certain kinds of granite, pegmatite and gneiss. In the U.S. it occurs at Haddam, Conn.; Greenfield Center near Saratoga Springs, N.Y.; Greenwood, Me.; and Manhattan Island. It is known also in the province of Quebec and near Gwelo, Rhodesia.

CHRYSOCOLLA, a hydrous copper silicate occurring as a decomposition product of copper ores. It is never found as crystals, but always as encrusting and botryoidal masses. It is green or bluish-green in colour, and often has the appearance of opal or enamel, being translucent and having a conchoidal fracture with vitreous lustre; sometimes it is earthy in texture. Not being a definite crystallized substance, it varies widely in chemical composition, the copper oxide (CuO), for example, varying in different analyses from 17% to 67%. The hardness (2–4) and specific gravity (2.0–2.8) are also variable. The mineral occurs in the upper parts of veins of copper ores, and has resulted from their alteration by the action of waters containing silica in solution. Pseudomorphs of chrysocolla after various copper minerals (*e.g.*, cuprite) are not uncommon. Chrysocolla is found in most copper mines. The name chrysocolla (from χρυσός, gold, and κόλλα, glue) was applied by Theophrastus and other ancient writers to materials used in soldering gold, one of which, from Cyprus, may have been identical with the mineral now known by this name. Borax, which is used for this purpose, has also been called chrysocolla.

CHRYSOLITE, a transparent green gem stone. The name chrysolite, meaning "golden stone" (χρυσός and λίθος), has been applied to various yellowish gems, notably to topaz, to some kinds of beryl and to chrysoberyl. The true chrysolite of the modern mineralogist is a pale green olivine (*q.v.*).

CHRYSOLORAS, MANUEL (or Emmanuel) (*c.* 1355–1415), a pioneer in spreading Greek literature in the west, was born at Constantinople. He was a pupil of Gemistus Pletho (*q.v.*). In 1393 the emperor Manuel Palaeologus sent him to Italy to seek the aid of the Christian princes against the Turks. About 1395 he became professor of Greek at Florence, where he taught for three years and became famous as a translator of Homer and Plato. In 1413 he went to Germany on an embassy to the emperor Sigismund, to fix the site of a general council. It was decided to hold the meeting at Constance, and Chrysoloras was on his way thither, having been chosen to represent the Greek Church, when he died suddenly on April 15, 1415. Only two of his works have been printed, his *Erotemata* (published at Venice in 1484), which was the first Greek grammar in use in the west, and *Epistolae III de comparatione veteris et novae Romae.*

John Chrysoloras, a relative of the above, who, like him, had studied and taught at Constantinople and had then gone to Italy, shared Manuel's reputation as one of those who spread the influence of Greek letters in the west. His daughter married Filelfo (*q.v.*).

CHRYSOPRASE is a transparent variety of cryptocrystalline silica of an apple-green colour (Gr. χρυσός, gold, and πράσον, leek), the latter being caused by the presence of nickel, probably in the form of hydrous silicate. A very similar artificial gem may be prepared by immersing chalcedony in solutions of nickel salts. On exposing a natural chrysoprase to light or heat its colour becomes paler, though this may be restored by placing the stone in a damp medium. It is surprising that the colour of the natural gem should be susceptible to the action of light and heat, while the artificial product is quite unaffected. (Max Bauer, *Precious Stones*, trans. by L. J. Spencer, 1904.)

CHRYSOSTOM (St. John Chrysostom) (Χρυσόστομος, golden-mouthed) (A.D. 345–407), the most famous Greek father,

was born at Antioch about A.D. 345. At the school of Libanius, the sophist, he gave early indications of his mental powers and love of classical culture. On being baptized (*c.* 370) by Meletius, bishop of Antioch, he retired to the desert, where for ten years he led a life of asceticism and study. Illness compelled him to return to the world, and in 381 he was ordained deacon and in 386 priest. He won great reputation by his preaching at Antioch, especially by his homilies on *The Statues*, delivered when the people feared the consequences of the destruction of the statues of the emperor Theodosius during a riot.

On the death of Nectarius, Chrysostom was appointed bishop of Constantinople (398). In this capacity he won the love of the people by his eloquent and devout homilies and by the application of his ample revenues to the establishment of hospitals. But his reforming zeal also made him many enemies. The clergy were forbidden to keep lay sisters as servants, aimless monks were confined to their monasteries and the extravagances of the court were strongly denounced. His enemies found a pretext for revenge in the shelter which he had given to four Nitrian monks who had been excommunicated by their bishop, Theophilus of Alexandria. Theophilus was invited to Constantinople (403) and, charging Chrysostom with Origenism, thrice summoned him to appear before a synod. He refused to appear and finally was declared deposed, arrested and exiled. The threats of the people, however, led the empress Eudoxia to recall him. Shortly afterward his denunciation of the honours addressed to a statue of the empress almost within the precincts of St. Sophia led to the calling of a second council, which again deposed him (404) for having resumed his functions without its permission. The people fired the cathedral and the senate house, but Chrysostom was hurried away to Cucusus (Cocysus) among the ridges of Mt. Taurus. His correspondence with the different churches and the recognition of his orthodoxy by Pope Innocent I and the emperor Honorius caused the emperor Arcadius to order his removal to the extreme desert of Pithyus. He died on the way at Comana in Pontus in 407. His exile gave rise to a schism and the Johannists (as they were called) only returned to communion with the bishop of Constantinople after the relics of the saint were brought back (437) and the emperor had publicly implored divine forgiveness. The feast of St. John Chrysostom falls on Nov. 13 in the Greek Church and on Jan. 27 in the Latin Church.

He elevates the ascetic element in religion and stresses the importance of knowing the Scriptures. In exegesis he is pure Antiochene, basing his expositions upon thorough grammatical study and not on the allegorical interpretation of Origen and the Alexandrian school. His writings contain the germ of later Eucharistic teaching and the invocation of the saints, but give no direct expression of the primacy of the pope or the necessity of private confession. As early as 425 Chrysostom was cited by the Greeks and Latins as a great authority.

His voluminous works include the early monastical treatises, including *On Priesthood*, the many homilies and commentaries written during his priesthood and episcopate, the best known being those *On the Statues* and on *Genesis, Psalms, Matthew and Romans*, and the letters which belong to the time of his exile and are valuable sources of history. The best edition is that of Migne (*Patrol. Graec.*, xlvii–lxiv) but many of the treatises have been edited more recently. English translations of some of the homilies and commentaries are in the Oxford Library of the Fathers. The most valuable authorities for his life are the ecclesiastical histories of Palladius, Socrates, Sozomen and Theodoret.

Baur, *S. Jean Chrysostome et ses oeuvres* (Louvain, 1907); J. M. Vance, *Beiträge Byzantinischen Kulturgeschichte aus den Schriften des Chrysostom* (Jena, 1907); A. Harnack, *Hist. of Dogma*, iii and iv.

CHRYSOTILE, a variety of serpentine, a hydrous silicate of magnesia, characterized by a fine, more or less silklike fibrous structure; this is the principal fibrous mineral used in commerce under the name asbestos (*q.v.*). (The name is derived from the Greek χρυσός, gold, and τίλος, down or hair, literally hair of gold.)

CHUB (*Leuciscus cephalus*), a cyprinid fish distinguished from others of the family in English rivers by the broad head and strong jaws and by feeding to a considerable extent on little fish. In England a length of 2 ft. and a weight of 8 lb. is reached, but on the continent 12 lb. In America the name is applied to other large-headed cyprinids; *e.g.*, the river chub (*Hybopsis kentuckiensis*) and the silver chub (*Semotilus corporalis*).

CHUBB, THOMAS (1679–1746), English deist, was born at East Harnham, near Salisbury, on Sept. 29, 1679. The son of a maltster, he was apprenticed to a glovemaker and subsequently worked for a tallow chandler. Later he lived for several years in the house of the master of the rolls, Sir Joseph Jekyll, apparently as a servent. He died in Salisbury on Feb. 8, 1746. He appeared as an author during the Arian controversy with an essay, *The Supremacy of the Father Asserted*, published on Whiston's authority in 1715. Mainly interesting as showing the spread of rationalism in the popular mind of the period, he was regarded by Voltaire as one of the most logical of his school. (*See* DEISM.) His chief works are *Discourse Concerning Reason* (1731); *True Gospel of Jesus Christ* (1739); and *Posthumous Works* (1748).

CHUBUT, a territory of the southern Argentine republic, part of what was formerly called Patagonia, bounded north by Río Negro, south by the military zone of Comodoro Rivadavia, east by the Atlantic and west by Chile. Pop. (1947) 58,856; area 65,669 sq.mi. Except for the valleys in the Andean foothills, which are fertile and well forested, and the land along the banks of the Chubut river, which flows entirely across the territory from the Andes to the Atlantic, the country is a steppeland covered with scanty dwarfed vegetation, with occasional shallow saline lakes. The larger rivers are the Chubut and the Senguer, the latter flowing into Lake Colhué Huapí. There are a number of large lakes among the Andean foothills, the best known of which are Fontana, Menéndez and General Paz, and, in the interior, Colhué Huapí and Musters, the latter named after the English naval officer who traversed Patagonia in 1870. Petroleum was found in the southern part of the territory toward the close of 1907, at a depth of 1,768 ft., and is being exploited. Chubut is known chiefly by the Welsh colony near the mouth of the Chubut river and its branch, the 16th of October colony, farther up the river. The chief town of the Welsh, Rawson, is the capital of the territory (pop. 1947, 9,605) and Port Madryn on Golfo Nuevo is its best port. Other colonies have been founded in the fertile valleys of the Andean foothills. More than 5,000,000 head of sheep grazed in Chubut in 1948. (C. E. Mc.)

CHUCK-A-LUCK or CHUCKERLUCK is a simplified version of the French game hazard. A layout numbered from one to six inclusive, a table, three dice and a dice cup are the essentials. Many times the dice are kept in a wire cage shaped like an hourglass. When the cage is reversed the dice fall through the centre opening to the bottom half. In this form the game is often referred to as the bird cage.

Players can wager any amount within the minimum and maximum limits on one or more of the six numbers. When all bets are down the dice are thrown, or the wire cage is upended. The uppermost faces of the three dice determine the outcome. If the player's selected number shows on one dice, he wins the amount he wagered; if on two dice, he wins double; if on three dice, he wins triple. The house breaks even when three different numbers are thrown; averages a profit of one unit when a pair and a single are thrown; averages a profit of two units when three of a kind are thrown. This amounts to 7.87% of the total.

Crown and anchor, known throughout the Commonwealth of Nations and often played in states contiguous to Canada, uses the same equipment as chuck-a-luck except for the markings on the dice. Instead of dots, the six sides bear various symbols: anchor, crown, club, diamond, heart and spade. The layout used displays these same symbols. Method of play, amount of pay-off and house percentage are identical with chuck-a-luck.

Hazard is the game from which chuck-a-luck evolved. In the United States almost all houses with hazard layouts refer to the game as chuck-a-luck.

The only material difference is in the layout. Besides the six chuck-a-luck numbers the hazard layout provides spaces for wagering on odd or even; on high or low; on triples (called raffles); and on any number the dice may total, from 4 to 17. Three, the lowest number possible, and 18, the highest number possible, can only be made with triples so they are not included in the regular line.

The pay-off on single numbers is the same as in chuck-a-luck. A player betting on high, low, odd, or even, collects even money if he wins. The banker's advantage lies in the fact that he does

not pay off if triples show. There are 216 possible combinations of 3 dice, 6 of which are triples. On this type of wager the house advantage is 2.78%.

If a player bets that any three of a kind will come up, he collects 30 to 1. (Correct odds—35 to 1; house advantage—13.9%.) If he bets that a particular triple will show, and he wins, he collects 180 to 1. (Correct odds—215 to 1; house advantage—16.2%.)

The percentage in favour of the house when a player bets on any particular number varies considerably, as shown by this table:

Combination	*Actual Odds*	*House Pays*	*House Advantage*
4 or 17	71 to 1	60 to 1	15.3%
5 or 16	35 to 1	30 to 1	13.9%
6 or 15	23 to 1	18 to 1	20.8%
7 or 14	67 to 5	12 to 1	9.7%
8 or 13	65 to 7	8 to 1	12.5%
9 or 12	8 to 1	6 to 1	22.2%
10 or 11	7 to 1	6 to 1	12.5%

To explain how the percentages are figured: suppose the chosen number is 6. There are 10 ways to make 6 with three dice—1–1–4, 1–4–1, 1–2–3, 1–3–2, 2–2–2, 2–1–3, 2–3–1, 3–1–2, 3–2–1, 4–1–1. The house does not pay off when 6 is made with three deuces, leaving 9 winning combinations for the player. There are 216 possible combinations. Deduct the 9 winning combinations. The odds are 207 to 9, or 23 to 1. The house pays 18 to 1. The difference between these two figures—24 for the house, 19 for the player—constitutes the house "edge" (advantage)—5/24 of 100 is 20.8%.

Should the house use a layout which reads 18 for 1, instead of 18 to 1, its percentage is increased, in this case 4.2%.

Poker dice requires five dice, a dice cup and a mat. The object is to score as high a poker hand as possible (*see* POKER). The ace has the highest value, the deuce the lowest. The hands run the same as in poker: five of a kind; four of a kind; full house; three of a kind; two pair; one pair. Usually the straight is not played, but when it is it ranks between three of a kind and a full house. Most players make the ace "wild," counting for any number the player wishes.

The first player throws all five dice. He may then put aside any combination he wishes, place the remaining dice in the cup, and throw again. Should he wish to play the first five thrown, he may do so. On the other hand, he may if he wishes pick up all five dice. It is sometimes played that each player in his turn is entitled to three casts of the dice. Subsequent players do likewise. The one getting the highest poker hand wins. Often the game is played with dice bearing regular playing card denominations: ace, king, queen, knave (jack), ten and nine. Occasionally pentagonal dice with values from ace to ten are used.

Many variations of poker dice are played as "counter games," so called because they are played on the counters of small retail stores with the merchant as banker. Each player has an equal chance. The advantage to the banker lies in the fact that the player must take his winnings, if any, in merchandise, upon which the owner of the store makes a profit. Such games therefore come under the heading of "trade stimulators."

Twenty-six is a counter game played for direct profit by the banker. Ten dice, a dice cup and a score card are required. The house always banks the game. The player first chooses any number from 1 to 6. The ten dice are thrown from the cup, the operator counts the number of times the selected number has shown, marks the total on the score card, and replaces the dice in the cup. The player is allowed 13 throws in all. If the number named by the player appears less than 11 times, or more than 25 times, the house pays the winner four units for every unit wagered. Sometimes the pay-off is increased if the player throws the chosen number more than 26 times.

Manufacturers of the paraphernalia guarantee their customers a profit of 15%. The dice girls who usually handle the game claim that the actual percentage is higher, often running as much as 20%. (S. M. M.)

CHUGUYEV, a town in the Kharkov county of the Ukrainian S.S.R., on the right bank of the Donetz river where the railway linking Kharkov to Kupyansk crosses the river; 49° 49′ N. lat., 36° 41′ E. long. Pop. (1926) 13,311.

CHUKCHI, a Mongoloid people inhabiting northeastern Siberia between Bering strait, Chaun bay and the Anadyr river. Culturally they belong to the circumpolar area, along with the Eskimo of North America and the Lapps, Samoyedes and other peoples of arctic Eurasia. Their language, however, is related only to those of the neighbouring Koryak and Kamchadal.

The Chukchi number about 12,000. Approximately 3,000 Maritime Chukchi live in permanent villages along the Arctic and Pacific coasts, subsisting primarily by fishing and the pursuit of seals, walrus and whales. About 9,000 Reindeer Chukchi wander in the interior, hunting, gathering and grazing their herds of domesticated reindeer on the tundra. Both groups live today in skin tents, but the Maritime Chukchi once occupied semisubterranean dwellings. Each community is politically independent under a nominal headman.

A man obtains a wife by serving her father for two or three years, after which he returns with his family to his own relatives. Polygamy is general and wife lending common. Clans are lacking, marriage with a first cousin is permitted and kinship conforms to the Eskimo pattern. Old people are respected, but when decrepit they sometimes commit suicide or compel their relatives to kill them.

The Chukchi people the unseen world with nature spirits who control natural phenomena, benevolent celestial spirits who receive sacrifices, evil spirits who cause sickness and death and various mythical monsters. Men who receive a "call" become shamans. They can commune with spirits, cause injuries through incantations and cure disease in spiritualistic seances. Summoning their familiar spirits by singing and drum beating, they become possessed by them, dance with frenzy and ventriloquistic utterances and ultimately fall into a trance, during which they purportedly visit the spirit world and rescue the wandering soul of the patient.

CHULALONGKORN, PHRA PARAMINDR MAHA (1853–1910), king of Thailand (Siam), eldest son of King Maha Mongkut, was born on Sept. 20, 1853, and succeeded his father on the throne on Oct. 1, 1868. The young king, who had according to custom been brought up in a Buddhist monastery, again retired into seclusion until he came of age in 1873, the government being entrusted to a regency. He then took the step, unprecedented for an eastern Asiatic potentate, of travelling outside his dominions, in India and the Dutch East Indies. The fruits of his appreciation of foreign institutions appeared in the reforms which he instituted in Thailand: the abolition of slavery, the simplification of court etiquette, the grant of liberty of conscience, the erection of schools and hospitals and the further development of the army and navy. He established a standard coinage, postal and telegraph services, and arranged for the policing, sanitation and lighting of Bangkok. Several of his sons, including the crown prince, were educated in England, and he himself visited Europe in 1897. He died at Bangkok on Oct. 23, 1910.

CHUMBI VALLEY, a valley connecting Tibet (*q.v.*) with the frontier of India. On the southern slopes of the Himalayas about 9,500 ft. above the sea, the valley is wedged in between Bhutan and Sikkim, and does not belong geographically but only politically to Tibet. The valley is sparsely cultivated on small flats by the river.

CHUNAR, a town and ancient fortress in Mirzapur district, Uttar Pradesh, India, on the south bank of the Ganges, 16 mi. S.S.W. of Benares. Pop. (1951) 8,176. The fort is on the summit of an abrupt rock commanding the river. It was once a place of great strength and contains the remains of a Hindu palace with interesting carvings. The town was once a European settlement for the invalid or veteran battalion of the East India company's army. In the church, the school, some ruined houses

and the graveyards are traces of that colony of war-worn exiles. The chief industry is quarrying the excellent Chunar sandstone, which was used notably for the buildings and sculptures of the Maurya and Gupta dynasties. In 1530 Chunar became the residence of Sher Shah the Afghan, and 45 years later was recovered by the emperor Akbar after a siege of six months. It fell to the English under Col. John Carnac in 1763 after long resistance. A treaty with the nawab of Oudh was signed there by Warren Hastings on behalf of the East India company in Sept. 1781, and for a time it enjoyed military importance as the frontier post of the company's jurisdiction.

CHUNCHO (ANTI), a term used to distinguish several South American Indian tribes on the eastern slope of the Andes, *e.g.*, the Arawakan (*q.v.*), Campa and others, from the Quéchua (*q.v.*) (Quichua) and the Aymara of the highlands. (J. H. Sd.)

CHUNGKING, former treaty port and commercial emporium of the isolated but important and densely peopled inland basin of Szechwan in western China. Pop. (1942) *c.* 1,000,000.

It is built on a rocky peninsula at the confluence of the Kialing, the most easterly of the great rivers draining the Red basin, with the Yangtze, the arterial line of communication in middle China. Chungking is therefore the natural gateway through which Szechwan communicates with the rest of China and the ocean. Moreover it gathers up the trade of eastern Tibet and of much of the north of Kweichow and Yünnan.

Chungking claims a history of more than 4,200 years. It was the birthplace of the imperial consort of the legendary Emperor Yu of the Hsia dynasty of the 22nd century B.C. When Emperor Wu of the Chou dynasty became ruler of China he made the viscount of Pahtzeku ruler over the territory now called Chungking and its neighbouring towns. It was made a kingdom about 340 B.C. Pahtzekuo was absorbed, as a county, under the Ch'in dynasty. The region of Chungking served occasionally as basis for independent rebellious leaders as Gen. Min Yu-chen at the end of the Yüan dynasty in 1367–68 and Chang Hsien-chung in 1645–51 at the end of the Ming dynasty. The Sino-British treaty of Chefoo in 1876 and the treaty of Peking in 1890 opened Chungking as a treaty port. The Japanese gained the right to establish a concession in Chungking after the treaty of Shimonoseki in 1895. The Japanese concession established in 1901 was taken over by the Chinese when war broke out in 1937.

Chungking became a municipality in Feb. 1923; on Nov. 20, 1937, Chungking became the wartime capital of China. In May 1939 it was placed under the control of the executive yuan and became a special municipality. After being officially named an auxiliary capital in Oct. 1940, its municipal limits were extended to include the four districts of Hsiaolungkan, Shapingpa, Tzechikow and Koloshan. Total area after expansion equalled 116 sq.mi. Extensive damage was caused by the repeated bombings by the Japanese from 1938 to 1941. Large sections of the downtown area were destroyed.

CHUPATTY. An Anglo-Indian term for an unleavened cake of bread. The word represents the Hindustani *chapati*, and is applied to the usual form of native bread, the staple food of upper India. The chupatty is generally made of coarse wheaten flour, patted flat with the hand and baked upon a griddle. In 1857 chupatties were circulated as a sign of discontent.

CHUPRIYA or CUPRIJA, a city in the Morava department of Serbia, Yugo. The old name was Korea Margi. (Pop., 1948, 9,819.) It is on the railway from Belgrade to Nish, and on the Morava, which is navigable up to this point by small sailing vessels. A light railway runs to Senje, which has lignite and other collieries that were seriously damaged in World War I. Fine Serbian cattle are bred in the neighbouring lowlands, and the town has a large sugar-beet factory and considerable trade in plums and farm produce. A government nursery for mulberry trees has been started; sericulture, which flourished in the middle ages, died down under Turkish rule. There is a government stud farm in the district. In World War I Chupriya was the central ammunition depot of the Serbian army; in World War II it was occupied by Germany. Cloth is woven, and there are glassworks at Paracin, 5 mi. S. Jagodina, 8 mi. N.W., is an important market town. Both are connected with Chupriya by rail and road.

The 14th-century Ravanitsa monastery, with a ruined fort and an old church (their walls and frescoes pitted by Turkish bullets), is about 7 mi. distant. Legend says that there the Serbian tsar Lazar (1374–89) was visited by an angel who bade him choose between an earthly and a heavenly crown. In accordance with his choice Lazar fell fighting at the battle of Kossovo. He was buried at Ravanitsa, but his body was afterward removed. His crucifix is treasured among the monastic archives, which also contain a charter signed by Peter the Great of Russia (1672–1725). Manasia (Manasiya), the still more celebrated foundation of Stephen, the son and successor of Lazar, lies 12 mi. N. of Ravanitsa. Built in a cleft among the hills, this monastery is enclosed in a fortress whose square towers and curtain without loopholes or battlements remain largely intact. Within the curtain stand the monastic buildings, a large garden and a cruciform chapel, with many curious old stone carvings, half hidden beneath whitewash. Numerous gifts from the Russian court, such as gospels lettered in gold and silver relief and jewelled crucifixes, are preserved on the spot, but the valuable library was removed in the 15th century to the monastery of Hilendar on Mt. Athos.

CHUQUISACA, a department of southeast Bolivia. It lies partly upon the eastern plateau of Bolivia and partly upon the great plains of the upper La Plata basin; area, 19,893 sq.mi. The Pilcomayo, a large tributary of the Paraguay, crosses northwest to southeast the western part of the department. The climate of the lowlands is hot, humid and unhealthful, but that of the plateau is salubrious, though subject to greater extremes in temperature. The seasons are sharply divided into wet and dry, the eastern plains becoming great lagoons during the wet season and parched deserts during the dry. The mineral resources are important, but are less developed than those of Potosí and Oruro. Grazing is the principal industry of the plains, and cattle, sheep, goats and llamas are raised and cereals grown in the fertile valleys of the plateau. Rough highways connect Chuquisaca with its neighbours on the north and west, and pack animals are the common means of transporting merchandise. The only railway and the best highway in the department connect Sucre with Potosí. Pop. (1950) 282,980, largely Indians and mestizos. The plateau Indians are generally Aymaras, but on the eastern plains there are considerable settlements of partly civilized Chiriguanos, of Guaraní origin. The department is divided (1950) into ten provinces, the greater part of the lowlands being unsettled and without effective political organization. Its principal towns are Sucre (*q.v.*), the capital, San Lucas, Tarabuco and Yotala.

CHUR, the capital of the Swiss canton of the Grisons (Fr. Coire, Ital. Coira). It lies 1,950 ft. above sea level on the valley floor of the Vorder Rhein in the angle between the Plessur and the Rhine, and is overshadowed by the Mittenberg and Pizokel, hills that guard the entrance to the deep-cut Schanfigg (Plessur) valley. Pop. (1950) 19,382. In 1920, 12,644 were German-speaking, 1,871 were Romansch and 943 Italian. Protestants numbered 9,783 and Roman Catholics 5,733. The old city is on the west, and includes the cathedral church of St. Lucius (traditionally a 2nd-century British king), which was built between 1178 and 1282 on the site of an older church. Opposite is the Bishop's palace and not far off is the Episcopal seminary (built on the ruins of a 6th-century monastic foundation). The Raetian museum contains a great collection of objects relating to Raetia. Chur is 74 mi. by rail from Zürich: it is the meeting point of routes from Italy over many Alpine passes (the Lukmanier, the Splügen, the San Bernardino) and is the centre of an active trade, particularly in wine from the Valtelline. Electric trains run to Davos, St. Moritz, Arosa and Andermatt.

The episcopal see is first mentioned in 452, but probably existed a century earlier. The bishop soon acquired great temporal powers, and became a prince of the empire in 1170. In 1392 he became head of the League of God's House (originally formed against him in 1367), one of the three Raetian leagues, but in 1526, after the Reformation, lost his temporal powers, having fulfilled his historical mission. The bishopric still exists, with jurisdiction over the cantons of the Grisons, Glarus, Zürich and the three forest cantons, as well as over Liechtenstein. The guild constitution of the city of Chur lasted from 1465 to 1839.

CHURCH, FREDERICK EDWIN (1826–1900), American landscape painter, was born at Hartford (Conn.) on May 4, 1826. He was a pupil of Thomas Cole at Catskill (N.Y.), where his first pictures were painted. Developing unusual technical dexterity, Church from the beginning sought for his themes such marvels of nature as Niagara Falls, the Andes, and tropical forests—he visited South America in 1853 and 1857—volcanoes in eruption, and icebergs, the beauties of which he portrayed with great skill in the management of light, colour, and the phenomena of rainbow, mist and sunset, rendering these plausible and effective. In their time these paintings awoke the wildest admiration and sold for extravagant prices, collectors in the United States and in Europe eagerly seeking them, though their vogue has now passed away. In 1849 Church was made a member of the National Academy of Design. His "Great Fall at Niagara" (1857) is in the Corcoran Art Gallery, Washington (D.C.), and a large "Twilight" is in the Walters Gallery, Baltimore (Md.). Among his other canvases are "Andes of Ecuador" (1855), "Heart of the Andes" (1859), "Cotopaxi" (1862), "Jerusalem" (1870), and "Morning in the Tropics" (1877). He died on April 7, 1900, at his house on the Hudson river above New York city, where he had lived and worked for many years. He was the most prominent member of the "Hudson river school" of American artists.

CHURCH, GEORGE EARL (1835–1910), American geographer, was born in New Bedford (Mass.), on Dec. 7, 1835. He was educated as a civil engineer, and was early engaged on the Hoosac tunnel. In 1858 he joined an exploring expedition to South America. During the American Civil War he served (1862–65) in the Army of the Potomac, rising to the command of a brigade and the rank of colonel; and in 1866–67 he was war correspondent of the *New York Herald* in Mexico. He explored the Amazon (1868–79), and gradually became the leading authority on that region of South America. In 1880 he was appointed U.S. commissioner to report on Ecuador, and in 1895 visited Costa Rica to report on its debt and railways. He wrote extensively on South and Central American geography, and became a vice-president of the Royal Geographical Society (London), and in 1908 president of the geographical section of the British Association.

CHURCH, SIR RICHARD (1784–1873), British military officer and general in the Greek army, was the son of a Quaker, Matthew Church of Cork. He was born in 1784, and at the age of 16 ran away from home and enlisted in the army. For this violation of its principles he was disowned by the Society of Friends, but his father bought him a commission in the 13th (Somersetshire) Light Infantry. He served in the demonstration against Ferrol, and in the expedition to Egypt under Sir Ralph Abercromby in 1801. He accompanied the expedition which landed in Calabria, and fought a successful battle against the French at Maida on July 6, 1806. In the summer of 1809 Church sailed with the expedition sent to occupy the Ionian islands. Here he formed a Greek regiment in English pay. It included many of the men who were afterwards among the leaders of the Greeks in the War of Independence. Church drew up a report on the Ionian islands for the Congress of Vienna, in which he advocated the retention of the islands under the British flag and the permanent occupation by Great Britain of Parga and of other formerly Venetian coast towns on the mainland, then in the possession of Ali Pasha of Iannina. In 1817 he entered the service of King Ferdinand of Naples as lieutenant-general, with a commission to suppress the brigandage then rampant in Apulia. In 1820 he was appointed governor of Palermo and commander-in-chief of the troops in Sicily. The revolution which broke out in that year led to the termination of his services in Naples.

In 1827 Church became commander-in-chief of the Greek army. The rout of his army in an attempt to relieve the acropolis of Athens, then besieged by the Turks, proved that it was incapable of conducting regular operations. The acropolis capitulated, and Sir Richard (he had been knighted by George IV.) turned to partisan warfare in western Greece. Here his activity had beneficial results, for it led to a rectification in 1832, in a sense favourable to Greece, of the frontier drawn by the Powers in 1830 (*see* his *Observations on an Eligible Line of Frontier for Greece*, 1830). Church had, however, surrendered his commission, as a protest against the unfriendly Government of Capo d'Istria, on Aug. 25, 1829. He lived for the rest of his life in Greece, was created general of the army in 1854, and died at Athens on March 30, 1873.

See *Sir Richard Church*, by Stanley Lane Poole (1890); Z. D. Feniman, *Some English Philhellenes* (1917); *Sir Richard Church in Italy and Greece*, by E. M. Church (Edinburgh, 1895), based on family papers (an Italian version, *Brigantaggio e società segrete nelle Puglie, 1817–1828*, executed under the direction of Carlo Lacaita, appeared at Florence in 1899). The ms. correspondence and papers of Sir Richard Church, in 29 vols., now in the British Museum (add. mss. 36,543–36,571), contain invaluable material for the history of the War of Greek Independence, including a narrative of the war during Church's tenure of the command, which corrects many errors in the published accounts and successfully vindicates Church's reputation against the strictures of Finlay, Mendelssohn-Bartholdy and other historians of the war (see *Cam. Mod. Hist.* x. p. 804).

CHURCH, RICHARD WILLIAM (1815–1890), English divine, son of John Dearman Church, brother of Sir Richard Church (*q.v.*), a merchant, was born at Lisbon on April 25, 1815, his early years being mostly spent at Florence. He went up to Wadham college, Oxford, in 1833, took first-class honours in 1836, and in 1838 was elected fellow of Oriel. He was appointed tutor of Oriel in 1839, and was ordained the same year. He was an intimate friend of J. H. Newman at this period, and closely allied to the Tractarian party. In 1841 No. 90 of *Tracts for the Times* appeared, and Church resigned his tutorship. In 1844–45 he was junior proctor, and in that capacity, in concert with his senior colleague, vetoed a proposal to censure Tract 90 publicly. In 1846 Church, with others, started *The Guardian* newspaper, and he was an early contributor to *The Saturday Review*. He accepted in 1852 the small living of Whatley in Somersetshire, near Frome. In 1869 he refused a canonry at Worcester, but in 1871 he accepted, most reluctantly (calling it "a sacrifice *en pure perte*"), the deanery of St. Paul's, to which he was nominated by W. E. Gladstone. Dean Church died on Dec. 9, 1890.

His chief pub. works are a *Life of St. Anselm* (1870); the lives of *Spenser* (1879) and *Bacon* (1884) in Macmillan's "Men of Letters" series; an *Essay on Dante* (1878); *The Oxford Movement* (1891), together with many other vols. of essays and sermons. A coll. of his journalistic arts. was pub. in 1897 as *Occasional Papers*.

See *Life and Letters of Dean Church*, by his daughter, M. C. Church (1895); memoir by H. C. Beeching in *Dict. Nat. Biog.*; and D. C. Lathbury *Dean Church* (1907).

CHURCH. The word church refers both to the Christian religious community and to the building used for Christian worship. This article, after discussing the etymology of the word itself, will deal separately with these two subjects.

Etymology of the Word Church.—According to most authorities, the word is derived from the Gr. κυριακόν (δῶμα), "the Lord's (house)," and is common to many Teutonic, Slavonic and other languages, under various forms—*e.g.*, Scottish *kirk*, Ger. *kirche*, Swed. *kirka*, Dan. *kirke*, Russ. *tserkov*, Bulg. *cerkova*, Czech. *cirkev*, Finn. *kirkko*, etc. The word was originally applied to the building used for Christian worship, and subsequently extended to the Christian community (*ecclesia*) itself. Conversely, the Greek word *ecclesia* (ἐκκλησία) was transferred from the community to the building, and is used in both senses, especially in the modern Romance and Celtic languages (*e.g.*, Fr. *église*, Welsh *eglwys*, etc.). The Gothic New Testament of Ulfilas has *aikklesjo*.

A. THE CHURCH: THE RELIGIOUS COMMUNITY

The English word "church" represents the Greek ἐκκλησία (naturalized in Latin as *Ecclesia*) in its specifically Christian use. Other uses of the Greek word shed no light on this, and may prove misleading if brought into comparison. As so used, its earliest appearance that we can date is in the Epistles of St. Paul, where it is evidently a familiar term. In the earliest of them the apostle

writes, "ye have heard of my manner of life in time past in the Jews' religion, how that beyond measure I persecuted the Church of God, and make havock of it." This phrase, *the Church of God* (*τὴν ἐκκλησίαν τοῦ Θεοῦ*), has a history behind it, which will show exactly in what sense it was here used.

In the Old Testament are two Hebrew words *'edah*, and *ḳahal*, which in the LXX. are indiscriminately rendered *συναγωγή* or *ἐκκλησία*. In the Pentateuch both alike signify the general assembly of the people of Israel during the Wanderings. The word *ἐκκλησία*, which is so far confined to Deuteronomy is in this connection a natural Hellenism. Elsewhere they mean the people itself, especially in its relation to God, with little or no reference to assembling. Striking examples are Nehemiah xiii. 1 where the phrase is *ἐκκλησία θεοῦ*, and Ps. lxxiv. 2, *τῆς συναγωγῆς σου*. The word *συναγωγή* is the more frequent, and this alone survived in current use among Hellenistic Jews in the sense of a local congregation, the familiar *synagogue*. What has to be considered is the reason why the other word was revived in Christian use. The origin and the essential character of the Church are involved in this enquiry.

As historical sources there is nothing else, except in some sections of the Acts, so entirely contemporary as St. Paul's Epistles; but in the Gospels and in the rest of the Acts, though the language may be coloured by later thought or experience, valuable material can be found. It is clear that the gospel began as a proclamation of the Kingdom of God (or of Heaven) having close affinity both with older Messianic prophecy referring to the lineage of David, and with more recent apocalyptic dreams. The proclamation was renewed in both aspects by the Apostles on the basis of belief in the resurrection and ascension of Jesus as the Christ. They gathered at Jerusalem a considerable number of disciples, forming a close community which was entered by the rite of baptism. There is reason to think that it was organized as a synagogue, one of the many in Jerusalem. In Aramaic "synagogue" is *knishta*. The Church is still so called by the Aramaic Christians of Palestine. Hence, perhaps, the word *synagogue* in James ii. 2. In the 4th century Epiphanius writes clumsily of the Ebionites, *συναγωγὴν καλοῦσι τὴν ἑαυτῶν ἐκκλησίαν καὶ οὐχὶ ἐκκλησίαν* (*Adv. Haeres*, i. ii. 18). We hear of it later (Acts xv.) as governed by James with a bench of Presbyters, the usual equipment of a synagogue. Some Pharisees and some priests joined, and the disciples regularly took part in the worship of the Temple; but the high priest and the Sanhedrim were hostile, making intermittent attempts to suppress the movement.

The episode of Stephen was a turning point. It is evident that this Hellenistic Jew was out of sympathy with the dominant religious sentiments of Jerusalem, probably shared by the Apostles and most of their disciples. He seems to have anticipated revolutionary changes, involving the suppression of the Mosaic ordinances and even of the Temple. His defence before the Sanhedrim was a rapid survey of Old Testament history. That history is a record of repeated relapses and ruin of God's chosen people, followed by the recovery of a small remnant, the common subject of prophecy. Stephen is just approaching a prophetic warning when he is silenced. It is probable that this worked in the mind of St. Paul, as preparation for his conversion. It became a prominent element in his teaching that the prophetic doctrine of the Remnant was being fulfilled. The Jewish people as a whole had fallen away by their rejection of Jesus as Messiah; those who accepted him were the faithful remnant which was to be the beginning of a reconstitution of God's people. He develops the argument in Romans ix., xi., but the conclusion is condensed into one remarkable sentence, Philip iii. 3, "We are the circumcision, who worship by the spirit of God, and glory in Christ Jesus, and have no confidence in the flesh." In current speech "the circumcision" meant the Jewish people regarded as bound in covenant to God. The actual rite of circumcision was being abandoned by Christians, and the sentence may be paraphrased: "Not those who practise the circumcision of the flesh, but the believers in Jesus as the Christ, are all that circumcision signifies, the covenanted People of God." It is the proper conclusion of Stephen's interrupted argument. St. Paul himself, having heard the argument and taken an active part in the persecution that followed, was soon afterwards convinced of its truth. So he said that he had persecuted "the *ecclesia* of God."

Why that Greek word? It occurs in Stephen's defence, but we do not know that he spoke in Greek. It would be familiar to any diligent reader of the LXX. and peculiarly appropriate, as it appears in Nehemiah xiii. 1, where *ἐκκλησία Θεοῦ* means the returning exiles, the Remnant on which the people of God was to be reconstructed. Its use appears to be a deliberate archaism: the exact equivalent *συναγωγή* being current, but unsuitable because of its immediate associations. In the Aramaic of the Christians of northern Syria *'edta*, a variant of the Hebrew *'edah*, is a precisely similar archaism. A common place of origin is, perhaps, to be found at Antioch. Hort's hesitating suggestion that it may have been derived from the saying of our Lord recorded in Matt. xvi. 18 is unacceptable in view of the improbability that Greek was the language used on that occasion. If not, the use of *ἐκκλησία* there will be due to later coloration.

The use of the word thus indicates the definite application of the prophetic teaching about the Remnant to the new Christian community. This application was not peculiar to St. Paul; it is found also in the words quoted by James in Acts xv. 16, "I will build again the tabernacle of David which is fallen, and I will build again the ruins thereof." The rest of his quotation marks a second crisis: "That the residue of men may seek the Lord, and all the Gentiles, upon whom my name is called." It was not long after the episode of Stephen that St. Peter startled the community at Jerusalem by baptizing Cornelius the centurion at Caesarea, an example which appears to have been soon followed at Antioch. The Jewish Commonwealth had always been open to proselytes who received circumcision and undertook to observe the Mosaic law, but these new entrants did not conform to either condition. When the community at Jerusalem consented, perhaps reluctantly, to the innovation, a complete break with Judaism was bound to come. St. Paul was inclined to press it, arguing (rather inconsistently with the doctrine of the Remnant) that Jews and Gentiles had to enter equally into the new covenant (*Gal.* iii.), but he afterwards spoke of the Gentiles as engrafted into the stock of Israel (*Rom.* xi. 17).

The Church now became a Diaspora, like that of Judaism, extended in all directions by the work of the Apostles and their helpers, but retaining its headquarters at Jerusalem. Consequently, the word *ecclesia* speedily went the same way that the word *synagogue* had gone; from being the designation of the whole People of God, it became the designation also of local groups. This development was already complete when St. Paul addressed his first extant epistle to "the Churches of Galatia." Of the organization of these Churches we know very little, for our only informants had no occasion to describe what was familiar to those for whom they were writing. Two opinions on the subject stand in sharp contrast. The one is linked with Luther's conception of an "invisible" Church, the members of which are known only to God. Rudolph Sohm is the ablest recent exponent of this idea. According to him, believers in Jesus as Christ were at first united only by a spiritual nexus; but before long there was an inevitable attempt to bind together all putative believers in an external organization, which eventually claimed to be the true Church of God, thus corrupting the pure spirituality of the Gospel. The other opinion postulates a completely organized society, existing from the beginning and continuing, not indeed without changes, but in consistent development through subsequent ages. In reply to Sohm, Harnack stated this with much exaggeration, asserting that the Church began with an "abundant and elaborate equipment," and even with a "legal code" of complicated structure.

The truth seems to lie in a synthesis of the ideal and the actual contained in these extremes. Lightfoot constructed such a synthesis in his essay on *The Christian Ministry*. What discipleship meant was a spiritual union with the risen Christ, but this union was held to be mediated by the rite of baptism. According to St. Paul, to be baptized was to "put on Christ," (*Gal.* iii. 27). Those who thus "live by the Spirit" must also "walk by the Spirit"

(*Gal.* v. 25). But this spiritual walking was strictly controlled by the Apostles, who ruled the several Churches in a most peremptory manner, "So ordain I in all the Churches" (I. *Cor.* vii. 17) says St. Paul about the conduct of marriage. Their control secured some measure of uniformity; "We have no such custom, neither the Churches of God" (I. *Cor.* xi. 16) was sufficient reason for repressing an innovation. To keep things in order they visited the Churches, personally or by delegates, and in case of need wrote directive letters. In a striking metaphor they are to the Church as the foundation to a house (*Eph.* ii. 20), and this cannot refer only to the original preaching of the Twelve, for St. Paul certainly included Barnabas and himself. Thus the Apostolate extended as the Church extended, and was in the way of becoming a permanent institution. Of the interior order of the local Churches we know at least the existence of Presbyters, some of whom were called ἐπίσκοποι or overseers. Details must be treated elsewhere. The Church of the first age, therefore, certainly had an official equipment and some rules of conduct, but probably nothing so elaborate as Harnack supposed. Nor was this equipment alien to the spiritual character of the Church, for every function depended on a special gift of the Spirit, however mediated (I. *Cor.* xii.; *Eph.* iv.). (*See* MINISTRY, THE CHRISTIAN; EUCHARIST.)

For 30 years after St. Paul's latest epistle we are left without information. The *First Epistle of Clement* supplies nothing new, but 20 years later the *Epistles of Ignatius* show a development. The five Churches in Asia which he addresses are equipped with a hierarchy of deacons and presbyters under a chief who bears the old title of ἐπίσκοπος (*bishop*) but no longer as a subordinate; he appears to execute in that one Church all the functions of an apostle. It is a disputed question whether his office has grown out of the presbyterate or is a continuation of the apostolate. If he were invariably attached to a single city, the former theory would be strengthened; but it is not so, for Ignatius calls himself "bishop of Syria," and some years later a single bishop is found serving the whole of Gaul north of the Narbonensian province, a truly apostolic charge. The system of city-bishops became general within the Roman empire, but in northern Europe and elsewhere the system of regionary bishops has always prevailed from the earliest times.

In Ignatius we find the important word "Catholic" describing the whole Church as distinct from local Churches. It is evidently a current term. He relates the bishop to a local Church as Jesus Christ to the Catholic Church (*Smyrn.* viii. 2). But in the *Martyrium Polycarpi*, some years later, the Church of Smyrna is called Catholic, perhaps as locally representing the whole. The word afterwards takes on a much larger content, indicating adhesion to the Christian religion as a whole, in contrast with the particularities of heresy, and so can be applied even to individual persons.

The First Reasoned Theory.—The 3rd century presents to us for the first time in its history a reasoned theory of the Church in the writings of St. Cyprian. He bases it on the episcopate, which he entirely identifies with the apostolate. Bishops are appointed by Christ himself, as the Apostles were, though the divine appointment is mediated by consecration, and even by some elements of popular election. The episcopate is one, and he illustrates its unity by terms borrowed from the Roman law of corporations. Nevertheless in each single place there is a single bishop who represents the whole, and of that place those inhabitants who communicate with the bishop, and none else, are in the communion of the Catholic Church. He has been generally followed, except in two particulars. He maintained: (1) that all bishops are precisely equal in authority, and (2) that a bishop is responsible only to God, and can be removed from his place, as he was appointed, only by God. The latter contention was confronted, in his own practice, by the obvious difficulty of ascertaining when the Divine judgment has fallen. A solution was soon found in the obvious inferiority of a single bishop to a council of bishops, which could therefore depose him. The case of Paul of Samosata settled this. Irenaeus had already noted the special weight of authority (*potentior principalitas*) exerted by the bishop of Rome, and this was equally true of the other great capital cities, Alexandria and Antioch; Constantinople was afterwards added next to Rome, and the honorary addition of the restored Jerusalem completed the system of the patriarchates which dominated the Church in the eastern half of the Roman empire from Italy to the Euphrates. In the same part of the empire there was a similar aggrandisement of the bishop seated in the metropolis of each province, who presided over a manageable council of comprovincial bishops, and acquired a commanding influence in their appointment; a system which with some differences, was gradually extended westward, and into the countries beyond the empire.

Such is the working system of the Catholic Church, evolved from elements which we can discern in the first age. From the 5th century onward it has been complicated by claims made for the Church of Rome based on the promise of the Keys to St. Peter in Matt. xvi. 19. This requires separate treatment. It has been complicated also by obstinate schisms. Donatism in Africa was a passing trouble. Such also was the Arianism of the Goths, which for three centuries delayed the settlement of the Church in the new nations carved out of the Western empire. More permanent has been the separation, much more racial than theological, of Nestorians and Monophysites in the East from the orthodoxy of Constantinople. A succession of temporary quarrels between Constantinople and Rome led to the great breach of 1054 still continuing. (*See* PAPACY.)

In the 16th century the Reformation shattered the unity of the Western Church, contrary to the intention of the promoters, who aimed at reforming the whole Church "in head and members." The predestinarianism alike of Luther and of Calvin brought in the theory of the Invisible Church mentioned above, reducing the hierarchy to the level of a not indispensable expedient. Luther, regarding the Visible Church in this light, gave the chief control of it to the civil magistracy, in which he was followed or preceded by the Swiss Reformers and by those of the middle Rhine. Calvin established at Geneva a system of Presbytery, modelled on indications drawn from the Pauline Epistles and the Acts, acting in close connection with the magistracy and this was carried by his disciple, Theodore Beza, to the Reformed of France, in complete independence of a hostile State. The Genevan model was extended to the Netherlands, and the independent Presbytery of Beza was planted in Scotland by John Knox, to be afterwards perfected by Andrew Melville. This Presbyterianism followed with some exaggeration the lines of the Cyprianic episcopacy, while dropping the title of *bishop*, with all the associations which had gathered round it. In the Scandinavian countries the historic episcopate was retained by the reformers, and in England the organized administration connected with it also remained almost intact. The doctrinal aspects of the Reformation do not concern us here. (*See* REFORMATION.)

English Puritanism began as a demand for further reformation on the Swiss model, and with Thomas Cartwright took the form of an assertion of the Divine right of Presbyterianism, but a native development became much more important. Robert Browne, and after him Henry Barrow, deduced from the doctrine of the Invisible Church their conception of the "gathered Church," a group of believers voluntarily associated in complete independence, which they declared to be the only true Visible Church of the New Testament. This *Independency*, dominant during the crisis of the Civil War, survived its political failures, and remains, with various modifications, one of the chief factors in the Protestantism of English-speaking countries, where a "Church" is usually taken to be such an association, whether in its original form of a single congregation or in a close-knit and extensive system like those of the various Methodist connections. These developments will be found severally treated elsewhere. In their mutual antagonisms the idea of the Christian Church as a whole has been almost lost sight of, but it has recently revived in more friendly discussion, and is found to be firmly rooted in history.

B. THE CHURCH BUILDING

It is generally held that the Church, when established as part of the organization of the Roman Empire, adopted for its buildings the plan of the secular basilica, and the name basilican has been given to the plan consisting of a long hall or nave with aisles, and with a projecting semicircular apse at the end opposite the main entrance. It should be remembered that the secular basilica followed no stereotyped form of plan, and that other influences may have combined to determine the plan assumed by the Christian church fabric. Further, although the term basilica was very commonly applied to early Christian churches, it was by no means confined to aisled buildings, but was also used of simpler structures. The internal arrangement of the apse, however, closely resembled that of the apse of the basilican law-court. The altar, on the chord of the apse, took the place of the altar on which oaths were taken by deponents: the seats of the bishop and clergy, ranged behind it, corresponded to those of the secular magistrates. The *cancelli* or screen, which divided the tribunal from the body of the court, became the barrier between the congregation and the sacred rites, and gave its name to the chancel of the church.

Circular Plan.—An alternative plan to that of the long aisled nave was the circular or polygonal plan, radiating from a central point, of which the most famous example is the church of San Vitale at Ravenna. This had its origin in the plan of the Christian baptistery, which was symbolically derived from the centralized plans of funeral monuments. The centralized church-plan, however, was provided with an encircling aisle or ambulatory, above which was a tribune or gallery, and with a chancel for the altar. Thus the fundamental characteristic of the Christian church-plan is its division into the nave for the worshippers and the chancel for the altar and clergy. Covering the main entrance to the nave there was frequently a narthex or vestibule, originally used by catechumens or by penitents excluded from participation in the holy mysteries. In the earliest churches the chancel was at the west end of the building, and the celebrant at the altar faced the congregation, but eventually the custom of placing the chancel at the east end of the church, which first appears in the basilicas of Ravenna prevailed, the celebrant still facing eastward. Beneath the altar there was often a crypt, the *martyrium* or *confessio*, so called from its traditional identity with the place of death or burial of the saint to whom the church was dedicated. The choir of singers was accommodated on the altar platform on either side of which were the *ambones* or pulpits from which the epistle and gospel were read.

In the larger Romanesque churches of western Europe, the aisled nave was practically universal, and the problem of covering these long structures with vaults of stone produced the characteristic art of the middle ages. Towers rose at the west ends of the aisles, and the erection of a tower on piers and arches between nave and chancel led to the development of the transept or cross-arm for purposes of abutment. It was, however, at the east end of the church that the principal development of plan took place. An aisled presbytery was interposed between the apse and the nave, and the aisles were in many instances continued round the apse, forming an ambulatory with a ring of chapels opening eastward from it. This arrangement, dictated by the requirements of processions and by the need of additional altars, became the regular plan of the French Gothic church, producing those magnificent *chevets* of apse and chapels which are the greatest masterpieces of mediaeval art. The process of enlargement and rebuilding, which attained its height in the thirteenth century, was due to the necessity of a larger ritual space and to the multiplication of endowments for masses. The east arms of churches were reconstructed on a large scale. Behind the altar in many churches rose the shrine of the local saint, the object of pilgrimages which enriched the church and its fabric. A Lady chapel, where the mass of the Blessed Virgin was celebrated daily, was often the most prominent of the chapels at the east end of the church, though its position on the plan varied. The transepts had their eastern aisles of chapels, and the spaces between the buttresses of the nave were utilised for the same purpose.

The Small Parish Church, usually an aisleless structure with nave and chancel, and with western or central tower, also underwent enlargement as local needs demanded. The nave was aisled; the chancel was lengthened; chapels were added at various points in the plan, which sometimes became extremely complex. Such enlargements and additions did not imply growth of population and the consequent need of a larger area for worshippers. Their cause was local anxiety to contribute to the pious work of church-building, and, where the means of benefactors allowed, to provide altars at which masses, maintained by their endowments, could be celebrated for the health of their souls. In certain districts church-building was encouraged by agricultural or commercial prosperity, by the existence of gilds which vied with one another in founding chantries, and by abundance of good local material and ease or cheapness of carriage. The architectural history of parish churches was much affected by the division of responsibility for cost between the rector, who met the repairs of the chancel, and the parishioners, who maintained the rest of the building by their contributions to the fabric fund or "works," under the administration of the church wardens, the *custodes fabricae* or *operis*.

It is often stated that the church architecture of the middle ages was dictated by an elaborate scheme of religious symbolism. While symbolical ideas entered into the adoption of certain types of plan, as in the transference, already mentioned, of the mausoleum plan to the baptistery, experience shows that the lay masons who usually carried out the work of building were guided by practical considerations, structural and ritual, whose free and natural expression would have been fettered by adherence to artificial rules of symbolism. Anomalies or deviations from regularity of plan, for which deep significances have been sought, can generally be assigned to errors of setting-out or to imperfect workmanship. The beauty and nobility of mediaeval church architecture is the result of the perfectly natural and unaffected response of the builders to the necessities of construction and to the immediate demands of the religious cult for which they laboured.

Artistic Development.—In some later mediaeval churches especially those of friars, wide naves were provided for preaching purposes. Usually the interior of the church was broken up by the screens which enclosed the chapels in the aisles and beneath the arches. Between the nave and chancel was the screen, the western counterpart, with open tracery in its panels, of the closed iconostasis of the Eastern Church: above it was the loft or gallery and the beam on which stood the crucifix. In cathedral and collegiate churches the screen was habitually a solid erection of stone, shutting off the choir services from the nave; while in monastic churches, including several of the English cathedrals, there were two transverse screens, the choir-screen with its *pulpitum* or loft to the east, and the rood-screen a bay or two west of it. As the middle ages advanced, with the growth of specialization in various departments of church fittings, the church became more and more the frame and setting for works of art in stone, marble, alabaster, wood and stained glass. From the beginning colour played a large part in internal effect, as in the mosaic incrustation of early Christian churches. Rough walls were plastered and pictures or patterns painted on the dry surface or in fresco. The window-openings were filled with stained glass; pigments were lavishly employed on ceilings, on the surface of piers and vaults, and on furniture. In such prodigality of colour the mediaeval mind found the fullest satisfaction of its religious ideals. By the contemplation of the works of art that filled his church, Suger, the great abbot of Saint-Denis, tells us that he felt himself lifted in spirit from the world to a purer clime; and in Italy and Flanders the art of painting grew to perfection in the decoration of church walls and altars.

The Renaissance.—In countries which embraced the Reformation, the work of church-building was checked. The prime motive which up to that time had prompted the rebuilding or extension of so many churches was gone and existing buildings fully met the requirements of reformed worship. But in any case the Gothic art of the middle ages was already disappearing before the revival of classic art which had its birth in Italy. The ruthlessness which mediaeval artists had shown to the work of their predecessors was pursued by the architects of the Renaissance, who thought nothing of sweeping away great historic monuments like St. Peter's at Rome to make way for buildings in their new style. At the same time, while this implied a change in methods of construction and decoration, those methods were adapted to the traditional Christian church plan, and the combination of classical architecture with mediaeval traditions of planning and design is nowhere more clearly seen than in St. Paul's Cathedral and in other churches designed by Wren and the English architects who followed in his footsteps. While the church plan, during the period of Renaissance influence, underwent some simplification, and the idea of the large auditorium or hall of worship superseded the practice of the middle ages and survived in the churches of the Gothic revival, it still retained the fundamental character of the plan which had approved itself as suitable for the needs of the early church and had reached its highest development in conformity with the requirements of mediaeval ritual. CHURCH AND STATE. The relation of Church and State in England, conveniently summed up in the word "establishment," is curiously complicated, including elements of great antiquity and arrangements made as recently as the year 1919. The antiquary, the historian, the lawyer, and the ecclesiastic find ample materials for their several studies in the Church of England as by law established. With the partial exception of Sweden, England was the only country in which the Reformation did not involve an almost complete breach with the system of the mediaeval Church. The main lines of the existing ecclesiastical system are mediaeval—the hierarchy, the parochial system, the convocations, the presence of the archbishops and bishops in the House of Lords, the canon law in so far as it was perpetuated by the legislation of Henry VIII., and the ecclesiastical courts. The Reformation effected a threefold change—social, doctrinal and constitutional. By the abolition of the monasteries, and the confiscation of the monastic property, the spiritual estate was weakened and impoverished: by changes in doctrine and discipline the Church of England abandoned the distinctive beliefs and devotions of mediaeval Christianity; and by the acceptance of the royal supremacy, it not only repudiated the authority of the Roman pope, but received the status and constitution of an independent national Church. Since the 16th century the acceptance of the policy of religious toleration by the State, and the evolution of democracy, have affected importantly the system of the Established Church. The growth of nonconformity, the expansion of the insular kingdom into the British empire, the secularisation of parliament, and the development of denominational self-assertion within the Church itself have all affected the existing relations of Church and State in England. Establishment in its present form may be conveniently considered under five heads, viz., the royal supremacy, the authority of parliament, the ecclesiastical courts, patronage, the tenure of the ancient endowments.

The Royal Supremacy. Henry VIII. forced the convocations to recognize his "headship" of the Church of England, but mitigated the unquestionable innovation by the pretence that he was but vindicating and restoring to the Crown the authority in ecclesiastical matters which was inherent in the monarchy by divine right, and had been recognized in practice until the usurpation of the Roman popes had obscured and superseded it. The revolutionary statutes which abolished the papal authority, and severed the national Church from the larger ecclesiastical system of which it had hitherto formed part, adopted a demurely constitutional tone, emphasizing the ancient independence and imperial self-sufficiency of the realm under its monarch. Thus the Restraint of Appeals, A.D. 1533, begins:

> Where by divers sundry old authentic histories and chronicles it is manifestly declared and expressed, that this realm of England is an empire, and so hath been accepted in the world, governed by one supreme head and king, having the dignity and royal estate of the imperial crown of the same, unto whom a body politic, compact of all sorts and degrees of people, divided in terms, and by names of spiritualty and temporalty, be bounden and ought to bear, next to God, a natural and humble obedience, etc.

That the royal authority over the Church in England had been very great in the past, and that the power of the popes had grown to exorbitant proportions in the period immediately preceding the Reformation, were unquestionable facts, and they gave plausibility to a contention which was, none the less, essentially untrue. The supremacy which the royal headship implied was a new thing in Christendom, and had no real precedents in history. It owed its origin to the novel conditions of the age, and its form to the masterful despot who arrogated it to himself. The functions withdrawn from the pope were accumulated on the monarch. Henry VIII., uniting in his own hands the plenitude of power both civil and spiritual, became in Bishop Stubbs's notable phrase, "the pope, the whole pope, and something more than the pope." (*Lectures on Mediaeval and Modern History*, p. 301.) So monstrous a claim could not be maintained. Under Elizabeth the royal supremacy was defined and delimited, and the much debated title, "head of the Church," was laid aside. Article XXXVII., which still binds the English clergy, claims for the sovereign "that only prerogative, which we see to have been given always to all godly Princes in holy Scriptures by God himself; that is, that they should rule all estates and degrees committed to their charge by God, whether they be Ecclesiastical or Temporal, and restrain with the civil sword the stubborn and evildoers." The Article adds that "the Bishop of Rome hath no jurisdiction in this Realm of England." So long as the royal supremacy was exercised by a sovereign who was himself a Christian man this definition served well enough: but the development of the English constitution from the practical autocracy of the Tudor sovereigns to the limited monarchy of their latest successors, has had its effect on the ecclesiastical system, and raised some formidable questions, of which the answer is not yet apparent.

Parliament.—The legislative authority of the mediaeval Church had been "spiritual." In the last resort the Church in England was governed by the canons of general councils and by the decretals of the popes. These controlled the action of the provincial convocations, which held the status of subordinate legislatures. The abolition of extra-national authorities, papal and conciliar, left nothing but the convocations of Canterbury and York in existence. In these circumstances the king and parliament may be said to have taken over the legislative functions of the pope and the general council. The Church of England before the Restoration was governed by ordinances and statutes. Church and nation were identified, at first practically, and then theoretically. The identification was defended with impressive eloquence by Hooker (d. 1600) and became the assumption of the English establishment. The convocations continued to legislate under the severe limitations imposed by 25 Henry VIII. cap. 19. (The Submission of the Clergy and Restraint of Appeals, 1534), and the mediaeval canon law retained under the same act a carefully restricted authority, but the right of parliament to legislate for the national Church even in "spiritual" matters was asserted and acted upon. The right was grounded on the Christian character of parliament, and on its essential function. Only by recognizing the legislative supremacy of parliament could the unity of the church-nation be secured. The 17th century witnessed the triumph of constitutional government, and the beginning of religious toleration. Legislative authority once shared between king and parliament became vested in parliament alone. The national Church was no longer governed partly by royal ordinance. James II.'s claim to the dispensing power was disallowed. While, however, the Act of Settlement (1701), provided that "whosoever shall hereafter come to the possession of this Crown shall join in communion with the Church of England, as by law established," it did not provide

against the danger implicit in a change in the religious character of parliament. The danger of Roman Catholic members was indeed guarded against by the Test act (1673); but 45 Presbyterians were admitted by the Act of Union with Scotland, A.D. 1707, and in the course of the 19th century parliament was opened to Nonconformists, Roman Catholics, Jews, and nonbelievers of every description. Parliament, thus frankly divorced from an ecclesiastical character, retained its ecclesiastical functions unaltered. The anomaly was apparent and increasingly resented as the Church of England, waking from the deep slumbers of the 18th century, felt and acted as a spiritual society. The influence of the Oxford movement tended powerfully in the same direction. In 1852 the convocations, which had been suspended for 135 years, again were permitted to function. Parliament ceased to be the sole organ of ecclesiastical legislation and henceforth found its action conditioned by the constitutional rights of a clerical legislature, subordinate indeed, but as ancient as itself, and within its own sphere as independent. Nor was this all. While parliament became patently unqualified for ecclesiastical legislation, its secular task, ever waxing with the expansion of the empire, and the complexity of social life, required its undivided concern. Urgent ecclesiastical reforms were postponed for no better reason than the congestion of parliamentary business. Accordingly the demand for better legislative machinery became general, and, in the general reconstruction of the national system which followed World War I, was met by the Enabling act (1919). A new body, the national assembly, was created consisting of three "houses"—the diocesan bishops, the members of both convocations and elected laity. To this body legislative authority, subject to the veto of either house of parliament, was given. Measures affecting the Church of England passed by the national assembly, certified as constitutional by an ecclesiastical committee created for the purpose, and approved by both houses of parliament, were to have the force of statutes on receiving the royal assent. The constitution of the national assembly both reserved unaltered "the powers belonging to the convocations of the provinces of Canterbury and York or of any House thereof," and prohibited the assembly from "exercising any power or performing any function distinctively belonging to the bishops in right of their episcopal office."

This devolution of legislative power by parliament to the assembly did not destroy the right of parliament to make laws for the Church of England, but rendered the exercise of that right abnormal and improbable. The right of a spiritual society to be truly autonomous in spiritual matters is obviously patient of large secular control in other directions: but the line between spiritual and secular is not always easy to trace, and the intermingling of secular and ecclesiastical interests in an anciently Christian community is extremely close. The Enabling act, however, carries the possibility of future trouble. In twice rejecting the Prayer Book measure (1927 and 1928) the house of commons has precipitated a conflict on a plainly spiritual issue, which must affect gravely the Establishment itself and may even bring about its destruction.

The Ecclesiastical Courts.—The unique character of the English Reformation as at once conservative and revolutionary is nowhere better exhibited than in the ecclesiastical courts. They are the provincial and diocesan courts of the mediaeval church, but they are held in the king's name, the law they administer is the king's ecclesiastical law, and they are subject to the appellant authority of the king's privy council. The modern system has departed in some important respects from that which the Reformation created. It is much more nakedly secular, for the study of canon law having practically ceased, and the race of canonists having died out, there was left no effective check on the secularizing tendency of the lawyers, who of old time cherished a professional dislike of the ecclesiastical jurisdiction, and sought after a simplification of the legal system which paid little heed to tradition and the claims of the "spiritualty." In the course of time, notably during the 19th century the limits of ecclesiastical jurisdiction have been greatly contracted by the withdrawal of suits relating to wills, marriage and tithes. Acts of parliament are administered in the ecclesiastical courts, not any more the mediaeval canon law, save where this has acquired statutory force from the provisional legislation of Henry VIII. The ecclesiastical judges are laymen and they acknowledge the supreme appellant authority of the judicial committee of the privy council. This progressive secularization of the church's legal system did not provoke resentment until, largely as a consequence of the Oxford movement, the ecclesiastical courts had to deal with suits affecting the interpretation of rubrics and doctrinal standards. That such subjects, affecting the worship and belief of churchmen, should be handled by secular lawyers, who might not even themselves be Christians, offended the new sense of ecclesiastical independence and did violence to the religious conscience of many devout persons. The courts were denounced as "Erastian," and a disposition manifested itself to repudiate their authority. This disposition has certainly been strengthened by the course of national politics. A breach has opened between the general sentiment of English churchmen and the settled policy of the state in the matters of religious education and the marriage law, which is not likely to be closed, and which tends to create an attitude of apprehension and suspicion not favourable to the easy working of the establishment. A commission charged to make recommendations for the reform of the ecclesiastical courts was appointed by the national assembly and issued its report. The general discontent with the existing courts, and the widely extended disposition to ignore their verdicts, add an element of special embarrassment to the problem of maintaining discipline in the church.

Patronage.—No part of the establishment is more distinctive, and none more perplexing than "patronage," that is the process by which clergymen are appointed to office. It presents a curious blending of ancient and modern elements. The higher ecclesiastics—bishops, deans, some canons and many incumbents—are appointed by the crown on the nomination of the prime minister. In the case of the ancient sees the mediaeval process is still followed, viz., *congé d'élire* to the dean and chapter accompanied by letters missive containing the name of the person whom they are desired to elect, confirmation by the archbishop, consecration, homage, and enthronement in the cathedral. In the case of modern sees which have no cathedral chapters, the bishop is appointed by letters patent. Two archbishops and 24 bishops sit in parliament the archbishops and the bishops of London, Durham and Winchester by right of their sees, the other bishops by seniority of their consecration The incumbents are nominated to the bishop of the diocese by patrons, who are either public (the lord chancellor, the bishops, colleges, the deans and chapters and other ecclesiastics holding patronage by title of their benefices) or private. The bishop has a limited power of refusing institution, but, in the absence of disqualification duly proved, he must institute and induct the patron's nominee to the benefice. This system is criticized as providing no adequate protection of parishioners against unsuitable appointments, and various projects for amending it have been advanced; but it is generally allowed that patronage, although anomalous in theory does not work badly, and there is no agreement as to a satisfactory substitute. The system is closely bound up with the method by which the parochial clergy are remunerated. The parish is also a benefice, and the incumbent possesses a life tenure of the endowment attached to it. This also is much objected to by reformers, but it does not lack apologists. Opinion, however, seems to be tending toward an age limit, which would remedy the principal fault of the existing system, viz., the incompetence of aged and ailing clergymen. A recent measure securing a modest pension at the age of 70 has laid the foundation for further reforms.

Tenure of the Ancient Endowments.—The Church of England is an endowed church, and, if it were disestablished, its claim to retain possession of the ancient endowments would certainly be disallowed. These endowments—fabrics, tithes, glebes, investments—are held by a multitude of corporations, sole and aggregate, on a service tenure, which is stated in the statutes which prescribe the functions of the bishops and clergy. Disestablishment would involve the dissolution of all these corporations. Such property as might be left to the disestablished church would be held under conditions which the Act of Disestablishment and Disendowment would create. It is the tenure of the endowments which forms now the most important aspect of the English establishment, and the prospect of their partial or total loss constitutes the weightiest of all arguments against disestablishment. Statesmen shrink from the grievous social and economic disturbance which disendowment would involve. Churchmen dread the loss of the material resources which maintain throughout the country the ministrations of religion. Neither the reluctance of the first nor the apprehensions of the last could avert the catastrophe if a breach between Church and State on a point of religious principle were to take place and prove incapable of remedy.

SCOTLAND

If the establishment in England is the most complicated, that in Scotland is the simplest which Christendom includes. In Scotland a "clean sweep" of the mediaeval system was effected. The Church was equipped with a new polity and in the course of history acquired an unprecedented independence. Its constitution as set out in the Church of Scotland Act, 1921, exhibits the model of "a free Church in a free State," such as Cavour projected in the middle of the 19th century. The 3rd Article "declaratory of the Constitution of the Church of Scotland in Matters Spiritual" runs thus:

This Church, as part of the Universal Church wherein the Lord Jesus Christ has appointed a government in the hands of Church office-bearers, receives from Him, its Divine King and Head, and from Him alone, the right and power subject to no civil authority to legislate and to adjudicate finally, in all matters of doctrine, worship, government, and discipline in the Church, including the right to determine all questions concerning membership and office in the Church, the constitution and membership of its Courts, and the mode of election of its office-

bearers and to define the boundaries of the spheres of labour of its ministers and other office-bearers. Recognition by civil authority of the separate and independent government and jurisdiction of this Church in matters spiritual, in whatever manner such recognition be expressed, does not in any way affect the character of this government and jurisdiction as derived from the Divine Head of the Church alone, or give to the civil authority any right of interference with the proceedings or judgments of the Church within the sphere of its spiritual government and jurisdiction.

Partly, this unique independence may be ascribed to the presbyterian polity which, while magnifying the ministry, gave comparatively little importance to any section of it. There was nothing in Scotland parallel in political function to the episcopate in England. Partly, the emphasizing of ecclesiastical independence has grown from the union of the kingdoms, at first personal and then, since 1707, parliamentary also. When the centre of national government had been removed to London, and Scottish business became a comparatively subordinate element in British politics, the Church of Scotland ceased to move the anxious concern of statesmen, while it acquired in the popular regard an ever greater importance as the principal, almost the only surviving, witness of an independent Scottish nationality. In more recent times, in Scotland as elsewhere, the secularization of society has deprived all ecclesiastical concerns of much of their former importance. The attendance of the king's commissioner at the annual meeting of the general assembly, and the appointment of a number of presbyterian ministers as royal chaplains, form the chief tokens of that connection with the State which is the core of establishment. The State exercises no control over legislation, or ecclesiastical courts or patronage. Establishment in Scotland has no practical importance, though unquestionably its sentimental value as a solemn recognition of national Christianity is still great, and its abolition would be regretted by many, probably by most, Scottish citizens.

THE UNITED STATES AND THE BRITISH DOMINIONS

Save in Great Britain, there is no established Church throughout the English-speaking communities, though the relations of the Churches to the State are everywhere friendly. Bryce's description of the situation in the United States holds good throughout the British Dominions:

The legal position of a Christian church is in the United States simply that of a voluntary association, or group of associations, corporate or unincorporate, under the ordinary law. There is no such thing as a special ecclesiastical law; all questions, not only of property but of church discipline and jurisdiction, are, if brought before the courts of the land, dealt with as questions of contract; and the court, where it is obliged to examine a question of theology, as for instance whether a clergyman has advanced opinions inconsistent with any creed or formula to which he has bound himself—for it will prefer, if possible, to leave such matters to the proper ecclesiastical authority—will treat the point as one of pure legal interpretation, neither assuming to itself theological knowledge, nor suffering considerations of policy to intervene.

Religious bodies are in so far the objects of special favour that their property is in most States exempt from taxation; and this is reconciled to theory by the argument that they are serviceable as moral agencies, and diminish the expense incurred in respect of police administration.

It would perhaps be true to say that there is an informal establishment of Christianity though not of the Churches. It is assumed that society is Christian. Religious acts inaugurate the sessions of the representative assemblies, and no public function would be considered complete without them. Undoubtedly this informal establishment by public opinion and social habit is menaced by the increasing secularization of society, but it is still strongly entrenched in the public sentiment of all English-speaking communities. Establishment in the true sense is limited to England and Scotland, and only in England does it possess any importance or present any legal and constitutional problems.

(H. H. H.)

CHURCH ARMY, an English religious organization, founded in 1882 by the Rev. Wilson Carlile (afterwards prebendary of St. Paul's), who banded together in an orderly army of "soldiers" and

convinced him that the moral condition of the lowest classes of the people called for new and aggressive action on the part of the Church, and that this work was most effectively done by laymen and women of the same class as those whom it was desired to touch. It is essentially a working men's and women's mission to working people. As the work grew, a training institution for evangelists was started in Oxford but soon moved (1886) to London where, in Bryanston Street near the Marble Arch, the headquarters of the army are now established. Working men are trained as evangelists and working women as mission sisters. Officers and sisters are paid a limited sum for their services either by the vicar or by voluntary local contributions. Church Army mission and colportage vans circulate throughout the country parishes, if desired, with itinerant evangelists who hold simple missions without charge and distribute literature. Each van missioner has a clerical "adviser." Missions are also held in prisons and workhouses, at the invitation of the authorities. In 1888 (before the similar work of the Salvation Army was inaugurated) the Church Army established labour homes in London and elsewhere, with the object of giving a "fresh start in life" to the outcast and destitute. The Army has lodging homes, employment bureaus, cheap food depots, old clothes department, dispensary and a number of other social works. There is also an extensive emigration system under which carefully tested men and families of good character, chiefly of the unemployed class, are placed in permanent employment in Canada through the agency of the local clergy.

See Carlile, art. "Church Army" in Hasting's *Encyclopaedia of Religion and Ethics;* Rowan, *Wilson Carlile and the Church Army; The Church Army Review,* and other publications of Headquarters.

CHURCH COUNCIL: *see* COUNCIL and CHURCH HISTORY.

CHURCHES OF CHRIST. The Churches of Christ are the conservative wing of the U.S. religious movement which began with the work of Thomas Campbell, a Presbyterian minister. In the *Declaration and Address* (1809), Campbell stated the principle that "where the Scriptures speak, we speak; where they are silent, we are silent." He and his son, Alexander, hoped to lead all Christian denominations into a single body united by adherence to the New Testament, considered as the final authority in all matters of church government and patterns of worship. The New Testament was to be treated as a religious constitution whose directions were to be minutely and literally followed. The Campbells seceded from the Presbyterian Church, and from 1813 till 1830 the movement was nominally Baptist. From the Baptists came the practice of total immersion as the only acceptable type of baptism. But beginning as early as 1826 many of the followers of the Campbells withdrew from the Baptist connection and organized Disciple congregations. (*See* DISCIPLES OF CHRIST.) These Disciples rejected all the historic creeds and the traditional dogmas, and many of them spoke of churches still using such creeds and dogmas as "man-made" in contrast with their own practice of following closely the text of the New Testament in polity, worship and organization.

As early as 1906 the conservative group, which constituted about one-fourth the Disciples, came to be recognized as a separate body. This group thought that the larger group had permitted unscriptural practices to creep into the church.

The Disciples and the Churches of Christ are congregational in their church government. They accept only two sacraments—baptism by immersion and the Lord's Supper, the communion service which is celebrated each Sunday, or Lord's Day, as they prefer to call it. Worship consists in reading the Bible and preaching, the observation of the Lord's Supper as a memorial and not a sacrifice, the contribution of money to the Lord's work, praying and singing without instrumental accompaniment. These conservatives objected to modernism, higher criticism of the Bible, missionary societies, mechanical instruments in worship services and acceptance of members from other church bodies which do not practice immersion on confession of faith. They do not fraternize with interdenominational agencies. The local churches, which are self-governing, have two classes of officials—elders and deacons. Persons are admitted to the church when three requirements are met: faith in Jesus Christ as the Son of God, repentance from sin and baptism by immersion.

About 80% of the Churches of Christ are in rural areas, and the greatest concentration is in Texas, Tennessee, Arkansas, Oklahoma, Alabama and Kentucky. Local churches maintain missionaries in Germany, the Netherlands, Belgium, France and other countries. There were about 12,000 churches in the United States, and outside the United States there were about 170 churches at mid-20th century. In the United States there were 16 colleges controlled by members of the churches, 15 homes for the aged and orphans and 45 periodicals published by individual members. There were approximately 800,000 members.

The title Church of Christ is used by other groups, including several old Congregational churches in New England. The title is frequently used by churches which belong to the Disciples and which have introduced practices regarded as unauthorized in

Scripture by the conservatives. (J. H. Cb.)

CHURCH HISTORY. In the following account of the historical evolution of the Church, the subject will be treated in three sections:—(A) The ancient Church to the beginning of the pontificate of Gregory the Great (A.D. 590); (B) The Church in the middle ages; (C) The modern Church.

A. THE ANCIENT CHURCH

The crucifixion of Jesus Christ resulted in the scattering of His followers, but within a short time they became convinced that He had risen from the dead, and would soon return to set up the expected Messianic kingdom, and so to accomplish the true work of the Messiah (*cf.* Acts i. 6 ff.). They were thus enabled to retain the belief in His Messiahship which His death had threatened to destroy permanently. This belief laid upon them the responsibility of bringing as many of their countrymen as possible to recognize Him as Messiah, and to prepare themselves by repentance and righteousness for the coming kingdom (*cf.* Acts ii. 21, 38, iii. 19 *et seq.*). In Jerusalem the new movement had its centre, and the church established there is rightly known as the mother church of Christendom. The life of the early Jewish disciples, so far as can be judged from our very meagre sources, was very much the same as that of their fellows. They continued faithful to the established synagogue and temple worship (*cf.* Acts iii. 1), and did not think of founding a new sect, or of separating from the household of Israel (*cf.* Acts x. 14, xv. 5, xxi. 21.) There is little evidence that their religious or ethical ideals differed in any marked degree from those of the more serious-minded among their countrymen, for the emphasis which they laid upon the need of righteousness was not at all uncommon. In their belief, however, in the Messiahship of Jesus, and their consequent assurance of the speedy establishment by Him of the Messianic kingdom, they stood alone. The first need of the hour, therefore, was to show that Jesus was the promised Messiah in spite of His crucifixion, a need that was met chiefly by testimony to the resurrection, which became the burden of the message of the early disciples to their fellow-countrymen (*cf.* Acts ii. 24 ff., iii. 15 ff., v. 31). It was this need which led also to the development of Messianic prophecy and the ultimate interpretation of the Jewish Bible as a Christian book (*see* BIBLE). The second need of the hour was to bring the nation to repentance and righteousness in order that the Kingdom might come (*cf.* Acts iii. 19).

Its Early Difficulties.—Meanwhile the new movement spread quite naturally beyond the confines of Palestine and found adherents among the Jews of the dispersion. Among the Christians who did most to spread the gospel in the Gentile world was the apostle Paul, whose conversion was the greatest event in the history of the early Church. In his hands Christianity became a new religion, fitted to meet the needs of all the world, and freed entirely of the local and national meaning which had hitherto attached to it. Paul saw in Jesus much more than the Jewish Messiah. He saw in Christ the divine Spirit, who had come down from heaven to transform the lives of men, all of whom are sinners. The Kingdom of which the early disciples were talking was interpreted by Paul as righteousness and peace and joy in the Holy Ghost (Rom. xiv. 17), a new principle of living, not a Jewish State. But Paul taught also, on the basis of a religious experience and of a distinct theory of redemption, that the Christian is freed from the obligation to observe the Jewish law. He thus did away with the fundamental distinction between Jews and Gentiles. The transformed spiritual life of the believer expresses itself not in the observance of Jewish law, but in love, purity and peace. This precipitated a very serious conflict, of which we learn something from the Epistle to the Galatians and the Book of Acts (xv. and xxii.).

It was Christianity in its universal form which won its great victories, and finally became permanently established in the Roman world. The appeal which it made to that world was many-sided. It was a time when men were awaking to the need of better and purer living. To all who felt this need Christianity offered high moral ideals, and a tremendous moral enthusiasm, in its devotion to a beloved leader, in its emphasis upon the ethical possibilities of the meanest, and in its faith in a future life of blessedness for the righteous. It was a time of great religious interest, when old cults were being revived and new were finding acceptance on all sides. Christianity, with its one God, and its promise of redemption and a blessed immortality based upon divine revelation, met as no other contemporary faith did the awakening religious needs. It was a time also of great social unrest. With its principle of Christian brotherhood, its emphasis upon the equality of all believers in the sight of God, and its preaching of a new social order to be set up at the return of Christ, it appealed strongly to multitudes, particularly of the poorer classes. That it won a permanent success, and finally took possession of the Roman world, was due to its combination of appeals.

Christianity was essentially a proselytizing religion, not content to appeal simply to one class or race of people, and to be one among many faiths, but believing in the falsity or insufficiency of all others and eager to convert the whole world, but it did not win its victory without a struggle. Superstition, misunderstanding and hatred caused the Christians trouble for many generations, and governmental repression they had to suffer occasionally, as a result of popular disturbances. No systematic effort was made by the imperial authorities to put an end to the movement until the reign of Decius (250–251), whose policy of suppression was followed by Diocletian (303 ff.) and continued for some years after his abdication. In spite of all opposition the Church steadily grew, until in 311 the emperor Galerius upon his death-bed granted it toleration; and in 313 the emperors Constantine and Licinius published the edict of Milan, proclaiming the principle of complete religious liberty, and making Christianity a legal religion in the full sense.

Constantine, recognizing the growing strength of the Church and wishing to enlist the loyal support of the Christians, treated them with increasing favour, and finally was baptized upon his death-bed (337). Under his successors, except during the brief reign of Julian (361–363), when the effort was made to reinstate paganism in its former place of supremacy, the Church received growing support, until, under Theodosius the Great (379–395), orthodox Christianity, which stood upon the platform adopted at Nicaea in 325, was finally established as the sole official religion of the state, and heathen worship was put under the ban. The union between Church and State thus constituted continued unbroken in the East throughout the middle ages. The division of the Empire resulted finally in the division of the Church, which was practically complete by the end of the 6th century, but was made official and final only in 1054, and the Eastern and Western halves, the Greek Catholic and the Roman Catholic Churches, went each its separate way.

For long after the establishment of Christianity as the State religion, paganism continued strong, especially in the country districts, and in some parts of the world had more adherents than Christianity, but at length the latter became, at any rate nominally, the faith of the whole Roman world. Meanwhile already before the 3rd century it went beyond the confines of the Empire in Asia, and by the end of the period was strong in Armenia, Persia, Arabia and even farther east. It reached the barbarians on the northern and western borders at an early day, and the Goths were already Christians of the Arian type before the great migrations of the 4th century began. Other barbarians became Christian, some in their own homes beyond the confines of the Empire, some within the Empire itself, so that when the hegemony of the West passed from the Romans to the barbarians the Church lived on. Thenceforth for centuries it was not only the chief religious, but also the chief civilizing, force at work in the Occident.

The Christian Life.—The most notable thing about the life of the early Christians was their vivid sense of being a people of God, called and set apart. They regarded themselves as separate from the rest of the world and bound together by peculiar ties: their citizenship was in heaven, not on earth (*cf.* Phil. iii.

20, and the epistle to Diognetus, c. 5), and the principles and laws by which they strove to govern themselves were from above: the present world was but temporary, their true life was in the future; Christ was soon to return, and the employments and labours and pleasures of this age were of small concern. The belief that the Church was a supernatural institution found further expression in the conviction of the presence and power of the Holy Spirit, supposed to be manifest in various striking ways, in prophecy, speaking with tongues and miracle-working. In this idea Paul also shared, but he carried the matter farther than most of his contemporaries and saw in the Spirit the abiding power and ground of the Christian life. Not simply in extraordinary phenomena, but also in the everyday life of Christians, the Holy Spirit was present, and all the Christian graces were the fruits (*cf.* Gal. v. 22). A result of this belief was to give their lives a peculiarly enthusiastic or inspirational character. Theirs were not the everyday experiences of ordinary men, but of men lifted out of themselves and transported into a higher sphere. With the passing of time the early enthusiasm waned, the expectation of the immediate return of Christ was widely given up, the conviction of the Spirit's presence became less vivid, and the conflict with heresy in the 2nd century led to the substitution of official control for the original freedom (*see* below). The late 2nd century movement known as Montanism was in essence a revolt against this growing secularization of the Church, but the movement failed, and the development against which it protested was only hastened. The Church as an institution now looked forward to a long life upon earth and adjusted itself to the new situation, taking on largely the forms and customs of the world in which it lived. This did not mean that the Church ceased to regard itself as a supernatural institution, but only that its supernatural character was shown in a different way; the early conviction of the essential difference between the life of this world and that of the next lived on, and, as the Church became increasingly a world-institution, found vent in monasticism, which was simply the effort to put into more consistent practice the other-worldly life, and to make more thoroughgoing work of the saving of one's soul.

There were Christian monks as early as the 3rd century, and before the end of the 4th monasticism (*q.v.*) was an established institution both in East and West. The monks and nuns were looked upon as the most consistent Christians, and were honoured accordingly. Those who did not adopt the monastic life endeavoured on a lower plane and in a less perfect way to realize the common ideal, and by means of penance to atone for the deficiencies in their performance. The existence of monasticism made it possible at once to hold up a high moral standard before the world and to permit the ordinary Christian to be content with something lower. With the growth of clerical sacerdotalism the higher standard was demanded also of the clergy, and the principle came to be generally recognized that they should live the monastic life so far as was consistent with their active duties in the world. The chief manifestation of this was clerical celibacy, which had become widespread already in the 4th century. Among the laity, on the other hand, the ideal of holiness found realization in the observance of the ordinary principles of morality recognized by the world at large, in attendance upon the means of grace provided by the Church, in fasting at stated intervals, in eschewing various popular employments and amusements, and in almsgiving and prayer. Christ's principle of love was widely interpreted to mean chiefly love for the Christian brotherhood, and within that circle the virtues of hospitality, charity and helpfulness were widely exercised.

Worship.—The primitive belief in the immediate presence of the Spirit affected the religious services of the Church. They were regarded in early days as occasions for the free exercise of spiritual gifts. As a consequence the completest liberty was accorded to Christians to take such part as they chose, it being assumed that they did so only under the Spirit's prompting. But the result of this freedom was confusion and discord, as is indicated by Paul's 1st Epistle to the Corinthians (*see* ch. xi., xiv.). This led to the erection of safeguards. Particular Christians were designated to take charge of the services, and orders of worship were framed out of which grew ultimately elaborate liturgies (*see* LITURGY). The Lord's Supper first took on a more stereotyped character, and prayers to be used in connection with it are found in the *Didachē* (ch. ix., x.). There developed in the 3rd or 4th century what is known as the *arcani disciplina*, or secret discipline of the Church, involving concealment from the uninitiated and unholy of the more sacred parts of the Christian cult, such as baptism and the eucharist, with their various accompaniments, including the Creed and the Lord's Prayer. The same interest led to the division of the services into two general parts, which became known ultimately as the *missa catechumenorum* and the *missa fidelium*,—that is, the more public service of prayer, praise and preaching open to all, including the catechumens or candidates for Church membership, and the private service for the administration of the eucharist, open only to full members of the Church in good and regular standing. Meanwhile, as the general service tended to grow more elaborate, the *missa fidelium* tended to take on the character of the current Greek mysteries (*see* EUCHARIST). Many of the terms in common use in them were employed in connection with the Christian rites, and many of the conceptions, particularly that of sharing in immortality by communion with deity, became an essential part of Christian doctrine. Thus the early idea of the services, as occasions for mutual edification through the interchange of spiritual gifts, gave way in course of time to the theory that they consisted of sacred and mysterious rites by means of which communion with God is promoted. The emphasis accordingly came to be laid increasingly upon the formal side of worship, and a value was given to the ceremonies as such, and their proper and correct performance by duly qualified persons, *i.e.*, ordained priests, was all-important.

Doctrine.—Two tendencies appeared in the thought of the primitive Church, the one to regard Christianity as a law given by God for the government of men's lives, with the promise of a blessed immortality as a reward for its observance; the other to view it as a means by which the corrupt and mortal nature of man is transformed, so that he becomes a spiritual and holy being. The latter tendency appeared first in the New Testament in Paul, and afterwards in the Gospel and 1st Epistle of John. The former found expression in most of our New Testament writings, in all of the apostolic fathers except Ignatius, and in the Apologists of the 2nd century. The two tendencies were not always mutually exclusive, but the one or the other was predominant in every case. Towards the end of the 2nd century they were combined by Irenaeus, bishop of Lyons. To him salvation bears a double aspect, involving both release from the control of the devil and the transformation of man's nature by the indwelling of the Divine. Only he is saved who on the one hand is forgiven at baptism and so released from the power of Satan, and then goes on to live in obedience to the divine law, and on the other hand receives in baptism the germ of a new spiritual nature and is progressively transformed by receiving the body and blood of the divine Christ in the eucharist. This double conception of salvation and of the means thereto was handed down to the Church of subsequent generations and became fundamental in its thought.

The twofold conception referred to had its influence also upon thought about Christ. The effect of the legal view of Christianity was to make Christ an agent of God in the revelation of the divine will and truth, and so a subordinate being between God and the world, the Logos of current Greek thought. The effect of the mystical conception was to identify Christ with God in order that by His incarnation the divine nature might be brought into union with humanity and the latter be transformed. In this case too a combination was effected, the idea of Christ as the incarnation of the Logos or Son of God being retained and yet His deity being preserved by the assertion of the deity of the Logos. The recognition of Christ as the incarnation of the Logos was practically universal before the close of the 3rd century, but His deity was still widely denied, and the Arian controversy which distracted the Church of the 4th century concerned the latter question. At the council of Nicaea in 325 the deity of Christ received official sanction and was given formulation in the

original Nicene Creed. Controversy continued for some time, but finally the Nicene decision was recognized both in East and West as the only orthodox faith. The deity of the Son was believed to carry with it that of the Spirit, who was associated with Father and Son in the baptismal formula and in the current symbols, and so the victory of the Nicene Christology meant the recognition of the doctrine of the Trinity as a part of the orthodox faith.

The assertion of the deity of the Son incarnate in Christ raised another problem which constituted the subject of dispute in the Christological controversies of the 4th and following centuries. What is the relation of the divine and human natures in Christ? At the council of Chalcedon in 451 it was declared that in the person of Christ are united two complete natures, divine and human, which retain after the union all their properties unchanged. This was supplemented at the 3rd council of Constantinople in 680 by the statement that each of the natures contains a will, so that Christ possesses two wills. The Western Church accepted the decisions of Nicaea, Chalcedon and Constantinople, and so the doctrines of the Trinity and of the two natures in Christ were handed down as orthodox dogma in West as well as East.

Meanwhile in the Western Church the subject of sin and grace, and the relation of divine and human activity in salvation, received special attention; and finally, at the 2nd council of Orange in 529, after both Pelagianism and semi-Pelagianism had been repudiated, a moderate form of Augustinianism was adopted, involving the theory that every man as a result of the Fall is in such a condition that he can take no steps in the direction of salvation until he has been renewed by the divine grace given in baptism, and that he cannot continue in the good thus begun except by the constant assistance of that grace, which is mediated only by the Catholic Church. This decision was confirmed by Boniface II., and became the accepted doctrine in the Western Church of the middle ages.

Organization.—The origin and early development of ecclesiastical organization are involved in obscurity.

In the earliest days the Church was regarded as a divine institution, ruled not by men but by the Holy Spirit. At the same time it was believed that the Spirit imparted different gifts to different believers, and each gift fitted its recipient for the performance of some service, being intended not for his own good but for the good of his brethren (*cf.* 1 Cor. xii.; Eph. iv. 11). The chief of these was the gift of teaching, that is, of understanding and interpreting to others the will and truth of God. Those who were endowed more largely than their fellows with this gift were commonly known as apostles, prophets and teachers (*cf.* Acts xiii. 1; 1 Cor. xii. 28; Eph. ii. 20, iii. 5, iv. 11). The apostles were travelling missionaries or evangelists; there were many of them in the primitive Church, and only gradually did the term come to be applied exclusively to the twelve and Paul. There is no sign that the apostles, whether the twelve or others, held any official position in the Church: that they had a large measure of authority goes without saying, but it depended always upon their brethren's recognition of their possession of the divine gift of apostleship, and the right of Churches or individuals to test their claims and to refuse to listen to them if they did not vindicate their divine call was everywhere recognized. Witness, for instance, Paul's reference to false apostles in 2 Cor. xi. 13, and his efforts to establish his own apostolic character to the satisfaction of the Corinthians and Galatians (1 Cor. ix. 1 ff.; 2 Cor. x. 13; Gal. i. 8 ff.), and the reference in Rev. ii. 2 to the fact that the Church at Ephesus had tried certain men who claimed to be apostles and had found them false.

Between the apostles, prophets and teachers no hard-and-fast lines can be drawn. The apostles were commonly missionary prophets, called permanently or temporarily to the special work of evangelization (*cf.* Acts xiii. 1), while the teachers seem to have been distinguished both from apostles and prophets by the fact that their spiritual endowment was less strikingly supernatural. The indefiniteness of the boundaries between the three classes, and the free interchange of names, show how far they were from being definite offices or orders within the Church.

But at an early day we find regular officers in this and that local Church, and early in the 2nd century the three permanent offices of bishop, presbyter and deacon existed at any rate in Asia Minor. Their rise was due principally to the necessity of administering the charities of the Church, putting an end to disorder and confusion in the religious services, and disciplining offenders. Regular officers within the local Churches gradually made their appearance, sometimes simply recognized as charged with responsibilities which they had already voluntarily assumed (*cf.* 1 Cor. xvi. 15), sometimes appointed by an apostle or prophet or other specially inspired man (*cf.* Acts xiv. 23; Titus i. 5; 1 Clement 44), sometimes formally chosen by the congregation itself (*cf.* Acts vi.). These men naturally acquired more and more, as time passed, the control and leadership of the Church in all its activities, and out of what was in the beginning more or less informal and temporary grew fixed and permanent offices, the incumbents of which were recognized as having a right to rule over the Church, a right which once given could not lawfully be taken away unless they were unfaithful to their trust. Not continued endowment by the Spirit, but the possession of an ecclesiastical office now became the basis of authority. The earliest expression of this genuinely official principle is found in Clement's Epistle to the Corinthians (ch. xliv.).

The earliest distinct evidence of the organization of Churches under a single head is found in the Epistles of Ignatius of Antioch, which date from the latter part of the reign of Trajan (*c.* 116). Ignatius bears witness to the presence in various Churches of Asia Minor of a single bishop in control, with whom are associated as his subordinates a number of elders and deacons. This form of organization ultimately became universal. Where there were one bishop and a number of presbyters and deacons in a church, the presbyters constituted the bishop's council, and the deacons his assistants in the management of the finances and charities and in the conduct of the services.

Meanwhile the rise and rapid spread of Gnosticism (*q.v.*) produced a crisis in the Church of the 2nd century, and profoundly affected the ecclesiastical organization. The views of the Gnostics, and of Marcion as well, seemed to the majority of Christians destructive of the gospel, and it was widely felt that they were too dangerous to be tolerated. The original dependence upon the Spirit for light and guidance was inadequate. The men in question claimed to be Christians and to enjoy divine illumination as truly as anybody, and so other safeguards appeared necessary. It was in the effort to find such safeguards that steps were taken which finally resulted in the institution known as the Catholic Church. The first of these steps was the recognition of the teaching of the apostles as the exclusive standard of Christian truth. This found expression in the formulation of our New Testament, and of an apostolic rule of faith, of which the old Roman symbol, the original of our present Apostles' Creed, is one of the earliest examples. Over against the claims of the Gnostics that they had apostolic authority, either oral or written, for their preaching, were set these two standards, by which alone the apostolic character of any doctrine was to be tested (*cf.* Irenaeus, *Adversus Haereses*, i. 10, iii. 3, 4; Tertullian, *De Prescriptione Haereticorum*). But these standards proved inadequate to the emergency, for it was possible, especially by the use of the allegorical method, to interpret them in more than one way, and their apostolic origin and authority were not everywhere admitted. In view of this difficulty, it was claimed that the apostles had appointed the bishops as their successors, and that the latter were in possession of special divine grace enabling them to transmit and to interpret without error the teaching of the apostles committed to them. This is the famous theory known as "apostolic succession." The idea of the apostolic appointment of church officers is as old as Clement of Rome, but the use of the theory to guarantee the apostolic character of episcopal teaching was due to the exigencies of the Gnostic conflict. Irenaeus (*op. cit.* iii. 3, iv. 26, 33, v. 20), Tertullian (*op. cit.*, 32) and Hippolytus (*Philosophumena*, bk. i., preface) are about our earliest witnesses to it, and Cyprian sets it forth quite clearly in his epistles. The Church was thus in possession not only of authoritative apostolic doctrine, but also of a permanent apostolic office, to which alone belonged the right to determine what that

doctrine is. The combination of this idea with that of clerical sacerdotalism completed the Catholic theory of the Church and the clergy. Saving grace is recognized as apostolic grace, and the bishops as successors of the apostles become its sole transmitters. Bishops are therefore necessary to the very being of the Church, which without them is without the saving grace for the giving of which the Church exists (*cf.* Cyprian, *Ep.* 33, "ecclesia super episcopos constituitur"; 66, "ecclesia in episcopo"; also *Ep.* 59, and *De unitate ecclesiae* 17).

These bishops were originally not diocesan but congregational, that is, each church, however small, had its own bishop. This is the organization testified to by Ignatius, and Cyprian's insistence upon the bishop as necessary to the very existence of the Church seems to imply the same thing. Congregational episcopacy was the rule for a number of generations. But after the middle of the 3rd century diocesan episcopacy began to make its appearance here and there, and became common in the 4th century under the influence of the general tendency toward centralization, the increasing power of city bishops, and the growing dignity of the episcopate (*cf.* canon 6 of the council of Sardica, and canon 57 of the council of Laodicea; and see Harnack, *Mission und Ausbreitung*, pp. 319 *seq.*). This enlargement of the bishop's parish and multiplication of the churches under his care led to a change in the functions of the presbyterate. So long as each church had its own bishop the presbyters constituted simply his council, but with the growth of diocesan episcopacy it became the custom to put each congregation under the care of a particular presbyter, who performed within it most of the pastoral duties formerly discharged by the bishop himself. The presbyters, however, were not independent officers. They were only representatives of the bishop, and the churches over which they were set were all a part of his parish, so that the Cyprianic principle, that the bishop is necessary to the very being of the Church, held good of diocesan as well as of congregational episcopacy.

The belief in the unity of the entire Church had existed from the beginning. Though made up of widely scattered congregations, it was thought of as one body of Christ, one people of God. This ideal unity found expression in many ways. Intercommunication between the various Christian communities was very active. Christians upon a journey were always sure of a warm welcome and hospitable entertainment from their fellow-disciples. Messengers and letters were sent freely from one church to another. Documents of various kinds, including gospels and apostolic epistles, circulated widely. Thus in various ways the feeling of unity found expression, and the development of widely separated parts of Christendom conformed more or less closely to a common type. It was due to agencies such as these that the scattered churches did not go each its own way and become ultimately separate and diverse institutions. But this general unity became official, and expressed itself in organization, only with the rise of the conciliar and metropolitan systems. Already before the end of the 2nd century local synods were held in Asia Minor to deal with Montanism, and in the 3rd century provincial synods became common, and by the council of Nicaea (canon 5) it was decreed that they should be held twice every year in every province. Larger synods representing the churches of a number of contiguous provinces also met frequently; for instance, in the early 4th century at Elvira, Ancyra, Neo-Caesarea and Arles, the last representing the entire Western world. Such gatherings were specially common during the great doctrinal controversies of the 4th century. In 325 the first general or oecumenical council, representing theoretically the entire Christian Church, was held at Nicaea. Other councils of the first period now recognized as oecumenical by the Church both East and West are Constantinople I. (381), Ephesus (431), Chalcedon (451), Constantinople II. (553). All these were called by the emperor, and to their decisions he gave the force of law. Thus the character of the Church as a State institution voiced itself in them (*see* COUNCIL).

The theory that the bishops are successors of the apostles, and as such the authoritative conservators and interpreters of apostolic truth, involves of course the solidarity of the episcopate, and the assumption that all bishops are in complete harmony and bear witness to the same body of doctrine. This assumption, however, has not always been sustained by the facts. Serious disagreements even on important matters developed frequently. As a result the oecumenical council came into existence especially for the purpose of settling disputed questions of doctrine, and giving to the collective episcopate the opportunity to express its voice in a final and official way. At the council of Nicaea, and at the oecumenical councils which followed, the idea of an infallible episcopate giving authoritative and permanent utterance to apostolic and therefore divine truth, found clear expression, and has been handed down as a part of the faith of the Catholic Church both East and West.

Meanwhile the Roman episcopate developed into the papacy, which claimed supremacy over the entire Christian Church, and actually exercised it increasingly in the West from the 5th century on. This development was forwarded by Augustine, who in his famous work *De civitate Dei* identified the Church with the Kingdom of God, and claimed that it was supreme over all the nations of the earth, which make up the *civitas terrena* or earthly state. Augustine's theory was ultimately accepted everywhere in the West, and thus the Church of the middle ages was regarded not only as the sole ark of salvation, but also as the ultimate authority, moral, intellectual and political. Upon this doctrine was built, not by Augustine himself but by others who came after him, the structure of the papacy, the bishop of Rome being finally recognized as the head under Christ of the *civitas Dei*, and so the supreme organ of divine authority on earth (*see* PAPACY and POPE).

B. THE CHRISTIAN CHURCH IN THE MIDDLE AGES

The middle ages came into being at the time when the political structure of the world, based upon the conquests of Alexander the Great and the achievements of Julius Caesar, began to disintegrate. They were present when the believers in Mohammed held sway in provinces which Alexander had brought under the influence of Hellenism; while the Lombards, the West Goths, the Franks and the Anglo-Saxons had established kingdoms in Italy, Spain, Gaul and Britain.

The East.—Ancient and mediaeval times were not separated by so deep a gulf in the East as in the West; for in the East the Empire continued to exist, although within narrow limits, until towards the end of the middle ages. Constantinople only fell in 1453. Ecclesiastical Byzantinism is therefore not a product of the middle ages; it is the outcome of the development of the eastern half of the empire from the time of Constantine the Great. Imperial power extended equally over State and Church. Since the emperor ruled the Church there was no longer any question of independence for the bishops.

The *orthodoxy* of the Eastern Church was also a result of the Church's development after the time of Constantine. In the long strife over dogma the old belief of the Greeks in the value of knowledge had made itself felt, and this faith was not extinct in the Eastern Church. But the strife over dogma ended with the 7th century. After the termination of the Monothelite controversy (638–680), creed and doctrines were complete; it was only necessary to preserve them intact. Theology, therefore, now resolved itself into the collection and reproduction of the teaching of ancient authorities. The great dogmatist of the Eastern Church, John of Damascus (*c.* 699–753), who stood on the threshold of the middle ages, formulated clearly and precisely his working principle: to put forward nothing of his own, but to present the truth according to the authority of the Bible and of the Fathers of the Church.

In the Eastern Church the religious interest concerned itself more keenly with the mystic rites of divine worship than with dogma. Here was more than knowledge; here were representations of a mystic sensuousness, solemn rites, which brought the faithful into immediate contact with the Divine, and guaranteed to them the reception of heavenly powers. We may gauge the energy with which the Greek intellect turned in this direction if we call to mind that the controversy about dogma was replaced by the controversy about images. This raged in the Eastern Church for more than a century (726–843), and only sank to rest when the

worship of images was unconditionally conceded. In this connection the image was not looked upon merely as a symbol, but as the vehicle of the presence and power of that which it represented.

Consistent with this circle of ideas is the cultivation of religious experience. A beginning had been made, in the 5th century, by the Neo-platonic Christian who addressed his contemporaries under the mask of Dionysius the Areopagite. He is the first of a series of theological mystics which continued through every century of the middle ages. It is this striving after religious experience that gives to the Oriental *monasticism* (*q.v.*) of the middle ages its peculiar character; in it the old Hellenic ideal of the wise man who has no wants, *αὐτάρκεια*, was from the first fused with the Christian conception of unreserved self-surrender to God as the highest aim and the highest good.

The Eastern Church, then, throughout the middle ages, remained true in every particular to its ancient character. It did not develop as did the Western Church during this period, but room for *expansion* was found in the new nations which had sprung into existence since the beginning of the middle ages: the Bulgarians, the Serbians, and the multifarious peoples grouped under the name of Russians. One outcome of this expansion was the impossibility of continuing to share the life of the Western Church. Neither in the East nor in the West was a *separation* desired; but it was inevitable, since the lives of East and West were moving in different directions.

Since the time when the church of eastern Syria had decided, in opposition to the church of the Empire, to cling to the ancient views of Syrian theologians—therefore also to the teaching and person of Nestorius—her relations were broken off with the church in western Syria and in Greek and Latin countries; but the power of *Nestorian* Christianity was not thereby diminished. Separated from the West, it directed its energies towards the East, and here its nearest neighbour was the Persian church. The latter followed, almost without opposition, the impulse received from Syria; from the rule of the patriarch Babaeus (498–503) it may be considered definitely Nestorian. Thus there survived in mid-Asia a widely-scattered remnant, which, although out of touch with the ancient usages of Christian civilization, yet in no way lacked higher culture. Nestorian philosophers and medical practitioners became the teachers of the great Arabian natural philosophers of the middle ages, and the latter obtained their knowledge of Greek learning from Syriac translations of the works of Greek thinkers.

Political conditions at the beginning of the middle ages favoured the Nestorian church, and the fact that the Arabs had conquered Syria, Palestine and Egypt, made it possible to exert an influence on the Christians in these countries. Of still more importance was the brisk commercial intercourse between central Asia and the countries of the Far East; for this led the Nestorians into China. But with the consolidation of Mohammedan power the greater part of Nestorian Christendom was swallowed up by Islam, and only remnants of this once extensive church have survived until modern times. The middle ages were even more disastrous for *Monophysite* Christianity; in their case there was no alternation of rise and decline, and there is only a long period of gradual exhaustion to chronicle, alike in Syria and in Egypt.

The West.—(i.) During the *early middle ages* the central fact in the history of the Church is the influence of the foundation of the Teutonic States. While the Eastern Church was stereotyping those peculiar characteristics which made her a thing apart, the Church of the West was brought face to face with the greatest revolution that Europe has ever experienced. At the end of the 6th century all the provinces of the Empire had become independent kingdoms, in which conquerors of Germanic race formed the dominant nationality. This is the great fact which stands out at the beginning of the history of the Church in the middle ages. The continuity of the political history of Europe was violently interrupted by the Germanic invasion, but not that of the history of the Church. Creed and dogma, above all, remained unchanged. The doctrinal decisions of the ancient Church remained the indestructible canon of belief, and what the theologians of the ancient Church had taught was reverenced as beyond improvement. The entire form of divine worship remained therefore unaltered. Even where the Latin tongue was not understood by the people, the Church preserved it in the mass and in the administration of the sacraments, in her exorcisms and in her benedictions. The organization of ecclesiastical offices; and the property and social status of the Church and of the hierarchy, remained unchanged.

Nevertheless, the new conditions did exercise the strongest influence upon the character of the Church. The churches of the Lombards, West Goths, Franks and Anglo-Saxons, all counted themselves parts of the Catholic Church; but the Catholic Church had altered its condition; it lacked the power of organization, and split up into territorial churches. Under the Empire the oecumenical council had been looked upon as the highest representative organ of the Catholic Church; but the earlier centuries of the middle ages witnessed the convocation of no oecumenical councils. Under the Empire the bishop of Rome had possessed in the Church an authority recognized and protected by the State; among the new territorial churches, respect for Rome and for the successor of Peter was not forgotten but had altered in character; legal authority had become merely moral authority; its wielder could exhort, warn, advise, but could not command. The bishops continued to meet in synods as before, but the councils became territorial synods; they were called together at irregular intervals by the king, and their decisions obtained legal effect only by royal sanction.

In the middle ages *the civilizing task of the Church* was first approached in England. Aldhelm (d. 709) and the Venerable Bede (d. 735) were the first scholars of the period. England was also the home of Winfrid Bonifatius (St. Boniface, d. *c.* 757), who, in co-operation with the bishops of Rome, began the reorganization of the Frankish church, which had fallen into confusion and decay during the political disorders of the last years of the Merovingians. It was Boniface, too, who, with the aid of numerous English priests, monks and nuns, introduced the literary culture of England into Germany.

Charlemagne (d. 814) built on the foundations laid by St. Boniface. The importance of Charlemagne's work, from the point of view of the Church, consists in his having led back the Frankish Church to the fulfilment of her functions as a religious and civilizing agent. This was the purpose of his ecclesiastical legislation. The principal means to this end taken by him was the raising of the status of the clergy. For the purpose of carrying out his ideas Charlemagne gathered round him the best intellects of Europe. None was more intimately associated with him than the Anglo-Saxon Alcuin (d. 804); but he was only one among many. Under this guidance theology flourished in the Frankish empire. It was as little original as that of Bede; for on the continent, too, scholars were content to think what those of old had thought before them. But in so doing they did not only repeat the old formulae; the ideas of the men of old sprang into new life. This is shown by the searching discussions to which the Adoptionist controversy gave rise. At the same time, the controversy with the Eastern Church over the adoration of images shows that the younger Western theology felt itself equal, if not superior to the Greek.

The second generation of Frankish theologians did not lag behind the first. Hrabanus of Fulda (who died archbishop of Mainz in 856) was in the range of his knowledge undoubtedly Alcuin's superior. He was the first learned theologian produced by Germany. His disciple, Abbot Walafrid Strabo of Reichenau (d. 849), was the author of the *Glossa Ordinaria*, a work which formed the foundation of biblical exposition throughout the middle ages. France was still more richly provided with theologians in the 9th century: her most prominent names are Hincmar, archbishop of Reims (d. 882), Bishop Prudentius of Troyes (d. 861), the monks Servatus Lupus (d. 862), Radbert Paschasius (d. *c.* 860), and Ratramnus (d. after 868); and the last theologian who came into France from abroad, Johannes Scotus Erigena (d. *c.* 880). The real strength of Erigena was in the field of speculative metaphysics; the controversy about

predestination, which, in the 9th century, Hincmar and Hrabanus fought out with the monk Gottschalk of Fulda, as well as the discussions that arose from the definition of the doctrine of transubstantiation by Radbert, enable us to gauge the intellectual energy with which theological problems were being handled.

Charlemagne followed his father's policy in carrying out his ecclesiastical measures in close association with the bishops of Rome. The relation was one of co-operation, without supremacy on either side. There were, indeed, forces tending in the contrary direction; and these were present in the Frankish empire. Evidence of this is given by the canon law forgeries of the 9th century: especially the great collection of the Pseudo-Isidorian Decretals (*see* DECRETALS), the fundamental idea being that all lay control in ecclesiastical affairs is wrong. For the moment, however, this party met with no success. Of more importance was the fact that at Rome the old conditions, the old claims, and the old law were unforgotten. For example, Nicholas I. (858–867) drew a picture of the divine right and unlimited power of the bishop of Rome, which anticipated all that the greatest of his successors were, centuries later, actually to effect. The time had not, however, yet come for the establishment of the papal world-dominion. For, while the power of Charlemagne's successors was decaying, the papacy itself became involved in the confusion of the party strife of Italy and of the city of Rome, and was plunged in consequence into such an abyss of degradation (the so-called Pornocracy), that it was in danger of forfeiting every shred of its moral authority over Christendom.

(ii.) During the central period of the Middle Ages the antagonism between the German conception of ecclesiastical affairs and Roman views of ecclesiastical law found inevitable expression. This was most obvious in the matter of appointment to bishoprics. At Rome canonical election was alone regarded as lawful; in Germany, on the other hand, developments since the time of Charlemagne had led to the actual appointment of bishops being in the hands of the king, although the form of ecclesiastical election was preserved.

The practice customary in Germany was finally transferred to Rome itself. The desperate position of the papacy in the 11th century obliged Henry III. to intervene. When, in Dec. 1046, after three rival popes had been set aside, he nominated Suidgar, bishop of Bamberg, as bishop of Rome before all the people in St. Peter's, the papacy was bestowed in the same way as a German bishopric; and what had occurred in this case was to become the rule. By procuring the transference of the patriciate from the Roman people to himself Henry assured his influence over the appointment of the popes, and accordingly also nominated the successors of Clement II.

His intervention saved the papacy. For the popes nominated by him, Leo IX. in particular, were men of high character, who exercised their office in a loftier spirit than their corrupt predecessors. They placed themselves at the head of the movement for ecclesiastical reform. But it was not possible for the relation between Empire and Papacy to remain what Henry III. had made it.

The original sources of this reform movement lay far back, in the time of the Carolingians. It has been pointed out how Charlemagne pressed the monks into the service of his civilizing aims; but he thereby alienated monasticism from its original ideals. These, however, had far too strong a hold upon the Roman world for a reaction against the new tendency to be long avoided. This reaction began with the reform of Benedict of Aniane (d. 821), the aim of which was to bring the Benedictine order back to the principles of its original rules. In the next century the reform movement acquired a fresh centre in the Burgundian monastery of Cluny. A large number of the reformed monasteries attached themselves to the congregation of Cluny, thus assuring the influence of reformed monasticism upon the Church, and securing likewise its independence of the diocesan bishops, since the abbot of Cluny was subordinate of the pope alone (*see* CLUNY, BENEDICTINES, and MONASTICISM). Everywhere the object was the same: the supreme obligation of the Rule, the renewal of discipline, and also the economic improvement of the monasteries. The reform movement had originally no connection with ecclesiastical politics; but that came later when the leaders turned their attention to the abuses prevalent among the clergy, to the conditions obtaining in the Church in defiance of the ecclesiastical law. "Return to the canon law!" was now the battle-cry. The programme of reform thus included the freeing of the Church from the influence of the State, the recovery of her absolute control over all her possessions, the liberty of the Church and of the hierarchy.

As a result, the party of reform placed itself in opposition to those ecclesiastical conditions which had arisen since the conversion of the Teutonic peoples. It was, then, a fact pregnant with the most momentous consequences that Leo IX. attached himself to the party of reform. For, thanks to him and to the men he gathered round him (Hildebrand, Humbert and others), their principles were established in Rome, and the pope himself became the leader of ecclesiastical reform. But the carrying out of reforms led at once to dissensions with the civil power, the starting-point being the attack upon simony, this term covering all transferences by laymen of ecclesiastical offices or benefices, even though no money changed hands in the process. Thus the lord who handed over a living was a simonist, and so too was the king who invested a bishop. The Church at first concentrated her attack upon investiture. In 1059 the new system of papal election introduced by Nicholas II. (*see* CONCLAVE) ensured the occupation of the Holy See by a pope favourable to the party of reform; and in 1078 Gregory VII. issued his prohibition of lay investiture. In the years of conflict that followed Gregory looked far beyond this point; he set his aim ever higher, until, in the end, his idea was to concentrate all ecclesiastical power in the hands of the pope, and to raise the papacy to the dominion of the world. Thus was to be realized the old dream of Augustine: that of a Kingdom of God on earth under the rule of the Church. But it was not given to Gregory to reach this goal, and his successors had to return again to the strife over investiture; and the long struggle ended in a compromise by the Concordat of Worms (1122), the essential part of which was that the Empire accepted the canonical election of bishops, while the Church acknowledged that the bishop held his temporal rights from the Empire, and was therefore to be invested with them by a touch from the royal sceptre. A similar solution was arrived at in England. In France the demands of the Church were successful to the same degree as in England and Germany, but without any conflict. Thus the Germanic element in the law regarding appointment to bishoprics was eliminated. Somewhat later it disappeared also in the case of the churches of less importance, patronal rights over these being substituted for the former absolute ownership. The pontificate of Alexander III. (1159–81) decided this.

The Teutonic peoples had been taking the lead in the expansion of Christianity; but the spirit of the Latin races now began to assert itself. Scholasticism, the new theology, had its home in the Latin countries. Reason as well as authority had been appealed to as the foundation of theology; but for the theologians of the 9th and 10th centuries, whose method had been merely that of restatement, *ratio* and *auctoritas* were in perfect accord. Then Berengar of Tours (d. 1088) ventured to set up reason against authority: by reason the truth must be decided. This involved the question of the relation in theology of authority and reason, and of whether the theological method is authoritative or rational. These questions Berengar could not settle; he was ruined by his opposition to Radbert's doctrine of transubstantiation. The Lombard Anselm (d. 1109), archbishop of Canterbury, was the first to deal with the subject. He took as his starting-point the traditional faith; but he was convinced that whoever has experience of the truths of the faith would be able to understand them, by the exercise of his natural reason.

It was a bold conception—too bold for the mediaeval world, for which faith was primarily the obligation to believe. It was easy, therefore, to understand why Anselm's method did not become the dominant one in theology. Not he, but the Frenchman Abelard (d. 1142), was the creator of the scholastic method. Abelard, too, started from tradition; but he discovered that the statements of

the various authorities are very often in the relation of *sic et non*, yes and no. Upon this fact he based his pronouncement as to the function of theology: it must employ the dialectic method to reconcile the contradictions of tradition, and thus to shape the doctrines of the faith in accordance with reason. By teaching this method Abelard created the implements for the erection of the great theological systems of the schoolmen of the 12th and 13th centuries: Peter Lombard (d. 1160), Alexander of Hales (d. 1245), Albertus Magnus (d. 1280) and Thomas Aquinas (d. 1275). They adventured a complete exposition of Christian doctrine that should be altogether ecclesiastical and at the same time altogether rational. In so doing they set to work to complete the development of ecclesiastical dogma; the formulation of the Catholic doctrine of the Sacraments was the work of scholasticism.

Canon law is the twin-sister of scholasticism. At the very time when Peter Lombard was shaping his Sentences, the monk Gratian of Bologna was making a new collection of laws. It was not only significant that in the *Concordia discordantium canonum* ecclesiastical laws, whether from authentic or forged sources, were gathered together without regard to the existing civil law; of even greater eventual importance was the fact that Gratian taught that the contradictions of the canon law were to be reconciled by the same method as that used by theology to reconcile the discrepancies of doctrinal tradition. Thus Gratian became the founder of the science of canon law, a science which, like the scholastic theology, was entirely ecclesiastical and entirely rational (*see* CANON LAW).

Like the new theology and the new science of law, the new monasticism was also rooted in Latin soil. The duty of the priest-monk is not only to work out his own salvation, but, by preaching and cure of souls, to labour for others. This was the dominant idea of the order of friars preachers founded in 1216 by St. Dominic (*see* DOMINIC, SAINT; DOMINICANS). It was also the basis of the order of friars minor, founded in 1210 (*see* FRANCIS OF ASSISI, ST.; FRANCISCANS). This alone would serve to indicate the remarkable deepening of the religious life that had taken place in the Latin countries. In the 12th century the most influential exponent of this new piety was Bernard (*q.v.*) of Clairvaux, who taught men to find God by leading them to Christ. Contemporary with him were Hugh of St. Victor (*q.v.*) and his pupil Richard of St. Victor (*q.v.*), both monks of the abbey of St. Victor at Paris, the aim of whose teaching was a mystical absorption of thought in the Godhead and the surrender of self to the Eternal Love. Under the influence of these ideas, in part purely Christian and in part Neoplatonic, piety gained in warmth and depth and became more personal; and though at first it flourished in the monasteries, and in those of the mendicant orders especially, it penetrated far beyond them and influenced the laity everywhere. The new piety did not set itself in opposition either to the hierarchy or to the institutions of the Church, such as the sacraments and the discipline of penance, nor did it reject those foreign elements (asceticism, worship of saints and the like) which had passed of old time into Christianity from the ancient world. Its temper was not critical, but aggressively practical.

All this meant a mighty exaltation of the Church, which ruled the minds of men as it had hardly ever done before. Nor was it possible that the position of the bishop of Rome, the supreme head of the Western Church, should remain unaffected by it. Two of the most powerful of the German emperors, Frederick I. and his son Henry VI., struggled to renew and to maintain the imperial supremacy over the papacy. But when at the peace of Venice (1177) Frederick recognized Alexander III. as pope, he relinquished the hope of carrying out his Italian policy; while Henry died at the early age of thirty-two (1197), before his far-reaching schemes had been realized.

The field was thus cleared for the full development of papal power. This had greatly increased since the Concordat of Worms, and reached its height under Innocent III. (1198–1216). Innocent believed himself to be the representative of God, and as such the supreme possessor of both spiritual and temporal power. He therefore claimed in both spheres the supreme administrative, legislative and judicial authority. The bishops described themselves as holding office "by grace of the Apostolic See," for they administered their dioceses as plenipotentiaries of the pope; and even the criminal jurisdiction of the church (*see* INQUISITION) became more and more concentrated in his hands. And just as he considered himself entitled to appoint to all ecclesiastical offices, so also he invested the emperor with his empire and kings with their kingdoms. Not only did he despatch his decretals to the universities to form the basis of the teaching of the canon law and of the decisions founded upon it, but he considered himself empowered to annul civil laws. Thus he annulled the Great Charter in 1215. Just as the Curia was the supreme court of appeal in ecclesiastical causes, so also the pope threatened disobedient princes with deposition, *e.g.*, the emperor Otto IV. in 1210, and John of England in 1212. But the papal claim to supreme temporal authority proved impossible to maintain, although Innocent III. had apparently enforced it. The long struggle against Frederick II., carried on by Gregory IX. (1227–41) and Innocent IV. (1243–54), did not result in victory; no papal sentence, but only death itself, deprived the emperor of his dominions; and when Boniface VIII. (1294–1303), who gave the papal claims to universal dominion their classical form, quarrelled with Philip IV. of France about the extension of the royal power, he could not but perceive that the national monarchy had become a force which it was impossible for the papacy to overcome.

(iii.) At the close of the middle ages we come to a period of disintegration. While the Church was yet at the height of her power began the great revolution which was to end in the disruption of that union between the Temporal and the Spiritual which, under her dominion, had characterized the life of the West. The Temporal now claimed its proper rights. The political power of the Empire, indeed, had been shattered; but this left all the more room for the vigorous development of national states, notably of France and England. At the same time intellectual life was enriched by a wealth of fresh views and new ideas, partly the result of the busy intercourse with the East to which the Crusades had given the first impetus, and which had been strengthened and extended by lively trade relations, partly of the revived study, eagerly pursued, of ancient philosophy and literature (*see* RENAISSANCE). The life of the Church, moreover, was affected by the economic changes due to the rise of the power of money as opposed to the old economic system based upon land.

The effects of these changes made themselves felt on all sides, in no case more strongly than in that of the papal claims to the supreme government of the world. Theoretically they were still unwaveringly asserted; but after Boniface VIII. no pope seriously attempted to realize them; to do so had in fact become impossible, for from the time of their residence at Avignon (1305–77) the popes were in a state of complete dependence upon the French crown. In France Philip IV.'s jurists maintained that the temporal power was independent of the spiritual. In Italy, a little later, Dante championed the divine right of the emperor (*De Monarchia*, 1311). In Germany, Marsiglio of Padua and Jean of Jandun, the literary allies of the emperor Louis IV., ventured to define anew the nature of the civil power from the standpoint of natural law, and to assert its absolute sovereignty (*Defensor pacis*, *c.* 1352); while the Franciscan William of Occam (d. 1349) examined, also in Louis' interests, into the nature of the relation between the two powers. He too concluded that the temporal power is independent of the spiritual, and is even justified in invading the sphere of the latter in cases of necessity.

While these thoughts were filling men's minds, opposition to the papal rule over the Church was also gaining continually in strength. The reasons for this were numerous, first among them being the abuses of the papal system of finance, which had to provide funds for the vast administrative machinery of the Curia. There was also the boundless abuse and arbitrary exercise of the right of ecclesiastical patronage; and further the ever-increasing traffic in dispensations, the abuse of spiritual punishments for worldly ends, and so forth. No means, however, existed of enforcing any remedy until the papal schism occurred in 1378. Such a schism as this, so intolerable to the ecclesiastical sense of the

middle ages, necessitated the discovery of some authority superior to the rival popes, and therefore able to put an end to their quarrelling. General councils were now once more called to mind; but these were no longer conceived as mere advisory councils to the pope, but as the highest representative organ of the universal Church, and as such ranking above the pope, and competent to demand obedience even from him. The council of Constance (1414–18) did actually put an end to the schism; but the reforms begun at Constance and continued at Basel (1431–49) proved insufficient. Above all, the attempt to set up the general council as an ordinary institution of the Catholic Church failed; and the Roman papacy, restored at Constance, preserved its irresponsible and unlimited power over the government of the Church (*see* PAPACY; CONSTANCE, COUNCIL OF; and BASEL, COUNCIL OF). Neither France nor Germany, however, was prepared to forgo the reforms passed by the council. France secured their validity, as far as she herself was concerned, by the Pragmatic Sanction of Bourges (July 7, 1438); Germany followed with the Acceptation of Mainz (March 26, 1439). The theory of the papal supremacy held by the Curia was thus at least called in question.
